* *Bulata.* In the twelfth edition of this work, allusion was made to a product analogous to gutta-percha, said to be produced by a tree, *Sapota Mulleri*, growing in great abundance in Dutch Guiana in S. America. Under the name of *bulata*, this product has recently attracted considerable attention, having been imported into England from Demarara. It is said to have properties which will render it, in some instances, a useful substitute for gutta-percha, which it resembles in elasticity and exceeds in ductility, while requiring a much higher heat to soften. Its solubilities in various menstrua do not seem to have been determined; but they are probably analogous to those of gutta-percha and caoutchouc. As above stated, it is the concrete juice of *Sapota Mulleri*, or the bullet tree. The idea is entertained that it may serve as a good insulating material for submarine telegraphic wires. Another possible substitute for gutta-percha has been found in the concrete juice of an *Apocynea* growing in Ceylon, named *Alstonia scholaris*. (*Pharm. Journ. and Trans.*, 2d ser., vi. 490, A. D. 1865.)—*Note to the thirteenth edition.*

now imported into Europe and this country. As found in commerce it is generally impure, containing fragments of vegetable matter and earth. From these it may be freed by kneading it in hot water, or by melting it with oil of turpentine, straining, and evaporating. It may also be purified by means of chloroform. One part of gutta-percha cut into small pieces, put into a flask with 20 parts of chloroform, and frequently shaken, will be fully dissolved in two or three days. To this solution, which cannot be readily filtered, add one-fourth of a part of water, shaking the mixture, and then allowing it to rest for two weeks. The impurities rise or sink, and the clear intervening liquid yields pure gutta-percha by the distillation of the chloroform. (*Chem. Cent. Blatt*, Feb. 1857, p. 108.)*

Properties. Gutta-percha is of a dull-white or whitish colour, of a feeble odour, tasteless, at ordinary temperatures hard and almost horny, somewhat flexible in thin pieces, having an unctuous feel under the fingers, and very tenacious. Its sp. gr. is 0·9791. (*Soubeiran.*) At about 120° F., it becomes softer and more flexible, but is still elastic, resisting, and tenacious. At 150° or 160°, it is soft, very plastic, and capable of being welded and moulded into any form. It is thus softened, whether by means of hot water or by dry heat. On cooling it reassumes its former state, and retains any form which may have been given to it. In the softened state it is readily cut with a knife, though with some difficulty when cold. Exposed to a heat of 330° it loses a portion of water, and on hardening becomes translucent and gray; but it recovers its original characters if immersed in water. Subjected to igneous distillation, it yields volatile products, resembling closely the volatile oil obtained from caoutchouc by the same process. Heated in an open vessel, it melts, foams up, and takes fire, burning with a brilliant flame and smoke. A portion thus melted retains the state of a viscid fluid on cooling. Gutta-percha is a non-conductor of electricity. It is insoluble in water, alcohol, alkaline solutions, and the weak acids. Ether and the volatile oils soften it in the cold, and imperfectly dissolve it with the aid of heat. Oil of turpentine dissolves it perfectly, forming a clear colourless solution, which yields it unchanged by evaporation. It is also dissolved by bisulphuret of carbon, chloroform, and benzole. According to Soubeiran, it contains, besides pure gutta-percha, small portions of a vegetable acid, casein, and two resins, one soluble in ether and oil of turpentine, the other in alcohol. (*Journ. de Pharm.*, 3e sér., xi. 22.) Freed from these impurities, it has an ultimate composition closely analogous if not identical with that of caoutchouc. For a particular account of the distinctive properties of pure gutta-percha, and the two resins mixed with it, the

* A more satisfactory method is probably by dissolving one part of gutta-percha in twenty of boiling benzole, shaking the solution frequently with sulphate of lime, which upon standing two or three days carries down with it the colouring matter, then decanting the clear liquid, and adding it, in small portions at a time, to alcohol, agitating continually. During this process the gutta-percha is deposited perfectly white. To dry it thoroughly requires an exposure of several weeks; but the result may be hastened by rubbing in a mortar. (*Journ. de Pharm.*, Août, 1863, p. 138.)—*Note to the twelfth edition.*

Pure white gutta-percha. For dental purposes, as for filling carious hollows, it is desirable that gutta-percha should be purified, and rendered perfectly white. But what is sold as such in the market is said to consist largely of the white oxide of zinc, and is on this account badly adapted to the purpose intended. Mr. F. Baden Benger recommends the following method of purification for dentists' use. He states that good crude gutta-percha will yield at least 75 per cent. of the purified. Four ounces of the gutta-percha, in small pieces, are to be digested for a few days with five pounds of methyllated chloroform; and the solution thus formed should be filtered in such a way as to permit little or no loss of chloroform. To the liquid thus filtered, which should be nearly colourless, an equal bulk of alcohol should be added, or a sufficiency to precipitate the gutta-percha, which will separate as a white mass. This is to be washed with alcohol, pressed in a cloth, and dried by exposure to the air. In this state, the gutta-percha is perfectly white, but too porous for use. To give it the proper consistence, it should be boiled for half an hour in a porcelain capsule, and rolled into cylinders while hot. The dentist can readily prepare this himself, and with sufficient economy if he guard against the loss of chloroform. This may be separated from alcohol by washing with water, and the alcohol from the water by distillation. (*Pharm. Journ. and Trans.*, Sept. 1868, p. 160.)—*Note to the thirteenth edition.*

reader is referred to an article by M. Payen, in the *Journ. de Pharm.* (3e sér., xxii. 183), also in the *Chem. Gaz.* (x. 353). According to Baumhauer, pure gutta-percha, as it issues from the tree, is a carbohydrogen, with the formula $C_{20}H_{16}$, which he calls *gutta*, and by the oxidation of which, in various degrees, the different bodies constituting gutta-percha are produced. This carbohydrogen can be separated by treating gutta-percha with dilute muriatic acid, and boiling the residue with ether, which deposits the gutta on cooling; but the ethereal treatment must be frequently repeated to obtain it quite pure. (*Journ. für prakt. Chem.*, lxxviii. 279.) M. Arppe considers gutta-percha as a mixture of six different resins, which may have been formed from a carbohydrogen $C_{10}H_8$. (See *Chem. Gaz.*, ix. 471.) This vegetable product resists putrefaction strongly; but in certain situations, as when employed to protect underground telegraph wires passing near the roots of the oak, it has been observed to undergo speedy decomposition, in consequence, as is supposed, of the action of fungi arising from sporules generated in such exposures. (*Pharm. Journ.*, xvii. 193.)

Gutta-percha has been applied to many useful and ornamental purposes. Its plasticity when moderately heated, great firmness and tenacity at ordinary temperatures, and insolubility in water and alcohol are the properties to which it chiefly owes its value. By immersing it in hot water, it is made susceptible of being formed into any desirable shape; so that utensils of various kinds, ornamental impressions, casts, sheets, bands, cords, sticks, tubes, &c., applicable to numerous purposes in the arts, may be made from it with great facility. To give it greater pliability, it is sometimes mixed with the tar resulting from the igneous decomposition of caoutchouc, or with its own tar and lampblack. It may be vulcanized, in the same manner as caoutchouc, and undergoes a similar change of properties. (See *Caoutchouc.*) In the dissolved state it may be employed as a varnish, impervious to moisture.

Medical Uses. Gutta-percha has been introduced into surgery, in order to preserve limbs and joints in fixed positions; and has been used beneficially in club-foot, fractures, and diseases of the joints. It is employed for these purposes in the shape of bands, two or three inches broad and about a line thick, which, being softened in water, are applied in this state, and, when they harden, form a firm case for the limb. Holes should be made through the bands, for the escape of the vapour from the surface. It may in some cases be applied by moulding it, in its soft state, upon the part to be kept at rest, as to the hip and adjacent parts of the body and thigh, in cases of hip-joint disease, for which, when dried, it will form a support equal to the most accurately carved wooden splint. It is also used for the formation of catheters and other tubes, splints, stethoscopes, bougies, specula, pessaries, and various other instruments useful in surgery. The author has seen it employed, in the form of a bandage, in fracture of the thigh, in the hospital at Edinburgh. Being softened by immersion in warm water at the time, it was applied without difficulty; and, hardening, afterwards, it acted as a splint to the injured limb. Vogel recommends the solution in bisulphuret of carbon as an application to the skin in incised wounds. The liquid speedily evaporates, producing a refrigerant effect; while the gutta-percha hardens, and holds the edges of the wound firmly together. According to Mr. Acton, the best substance for protecting the surface from the contact of poisons, contagions, &c., is prepared by dissolving with a gentle heat a drachm of gutta-percha in an ounce of benzole, and ten grains of caoutchouc in the same quantity of the same menstruum, and mixing the solutions. It may be applied by a brush, and a delicate film is left by the evaporation of the liquid. A saturated solution in chloroform is very useful in slight superficial injuries and in various chronic affections of the skin. It is applied by means of a camel's-hair pencil, and forms, on the evaporation of the solvent, a thin, elastic covering, which completely excludes the air, and acts like an artificial cuticle to the part. The crusts or scales should be previously removed by poultices or alkaline solutions. The affections in which it has been found most efficacious are the dry scaly and tubercular diseases of the skin, especially psoriasis. It has been used also to render the

variolous eruption abortive. The preparation is now officinal under the name of *Liquor Gutta-perchæ.* (See *Part II.*) Another application of gutta-percha is to serve as a vehicle of certain caustic substances, particularly chloride of zinc, and caustic potassa. The preparation is made by reducing the caustic substance to fine powder, and then thoroughly mixing it with its weight of gutta-percha, melted at the lowest possible temperature. (See *Potassa*, and *Zinci Chloridum.*) A great advantage of the preparation is that it may be made into any desirable form, and will retain that form without spreading when applied.

HÆMATOXYLON. *U. S.*

Logwood.

The wood of Hæmatoxylon Campechianum. *U. S.*

Off. Syn. HÆMATOXYLI LIGNUM. *Logwood.* The sliced heart-wood of Hæmatoxylum Campechianum. *Br.*

Bois de Campêche, *Fr.;* Blutholz, Kampeschenholz, *Germ.;* Legno di Campeggio, *Ital.;* Palo de Campeche, *Span.*

HÆMATOXYLON. *Sex. Syst.* Decandria Monogynia. — *Nat. Ord.* Fabaceæ or Leguminosæ.

Gen. Ch. Calyx five-parted. *Petals* five. *Capsule* lanceolate, one-celled, two-valved, with the valves boat-form. *Willd.*

Hæmatoxylon Campechianum. Willd. *Sp. Plant.* ii. 547; Woodv. *Med. Bot.* p. 455, t. 163; Carson, *Illust. of Med. Bot.* i. 33, pl. 25. This is a tree of middle size, usually not more than twenty-four feet high, though, under favourable circumstances, it sometimes rises forty or fifty feet. The trunk, seldom exceeding twenty inches in diameter, is often very crooked, and is covered with a dark rough bark. The branches are also crooked, with numerous smaller ramifications, which are beset with sharp spines. The sap-wood is yellowish, but the interior layers are of a deep-red colour. The leaves are alternate, abruptly pinnate, and composed of three or four pairs of sessile, nearly obcordate, obliquely nerved leaflets. The flowers, which are in axillary spikes or racemes near the ends of the branches, have a brownish-purple calyx and lemon-yellow petals. They exhale an agreeable odour, said to resemble that of the jonquil.

The tree is a native of Campeachy, the shores of Honduras Bay, and other parts of tropical America; and has become naturalized in Jamaica. The wood, which is the part used in medicine, is a valuable article of commerce, and largely employed in dyeing. It comes to us in logs deprived of the sap-wood, and having a blackish-brown colour externally. For medical use it is cut into chips, or rasped into coarse powder, and in these states is kept in the shops.

Properties. Logwood is hard, compact, heavy, of a deep-red colour becoming dark by exposure, of a slight peculiar odour, and a sweet, somewhat astringent taste. It imparts its colour to water and to alcohol. The infusion made with cold water, though red, is less so than that with boiling water. It affords precipitates with sulphuric, nitric, muriatic, and acetic acids, alum, sulphate of copper, acetate of lead, and sulphate of iron, striking a bluish-black colour with the last-mentioned salt. (*Thomson's Dispensatory.*) Precipitates are also produced with it by lime-water and gelatin. Chevreul found in logwood a volatile oil, an oleaginous or resinous matter, a brown substance the solution of which is precipitated by gelatin (*tannin*), another brown substance soluble in alcohol but insoluble in water or ether, an azotized substance resembling gluten, free acetic acid, various salts, and a peculiar principle, called *hematoxylin* or *hematin*, on which the colouring properties of the wood depend. This is obtained by digesting the aqueous extract in alcohol, evaporating the tincture till it thickens, then adding a little water, and submitting the liquid to a new but gentle evaporation. Upon allowing it to rest, hematoxylin is deposited in crystals, which may be purified by washing with alcohol and drying. Thus procured, the crystals are

taining, of a yellowish rose colour, bitterish, acrid, and slightly astringent to the taste, readily soluble in boiling water, forming an orange-red solution which becomes yellow on cooling, and soluble also in alcohol and ether. According to Erdman, who obtained hematoxylin by the process of Chevreul, substituting ether for alcohol, its crystals, when quite pure, are yellow, without a tinge of redness; its taste is sweet, like that of liquorice, without bitterness or astringency; and it is not of itself a colouring substance, but affords beautiful red, blue, and purple colours, by the joint action of an alkaline base and the oxygen of the air. It consists of carbon, hydrogen, and oxygen. (*Journ. de Pharm.*, 3e sér., ii. 293.) Its formula in crystals is given as $C_{32}H_{14}O_{12}+2HO$, or $C_{32}H_{14}O_{12}+6HO$, according to the amount of its water of crystallization. (*Chem. Gaz.*, June 15, 1859, p. 227.) It is sometimes found in distinct crystals in the crevices of the wood.

Medical Properties and Uses. Logwood is a mild astringent, devoid of irritating properties, and well adapted to the treatment of that relaxed condition of bowels which is apt to succeed cholera infantum. It is also occasionally used with advantage in ordinary chronic diarrhœa and chronic dysentery. It may be given in decoction or extract.

HEDEOMA. *U. S.*

Hedeoma. American Pennyroyal.

Herb of Hedeoma pulegioides. *U. S.*

This herb, first attached to the genus *Melissa*, and afterwards to *Cunila*, is at present universally considered by botanists as belonging to the *Hedeoma* of Persoon. It has been very erroneously confounded by some with *Mentha Pulegium*, or European pennyroyal.

Hedeoma. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Lamiaceæ or Labiatæ.

Gen. Ch. Calyx bilabiate, gibbous at the base, upper lip three-toothed, lower two; dentures all subulate. *Corolla* ringent. *Stamens* two, sterile; the two fertile stamens about the length of the corolla. *Nuttall.*

Hedeoma pulegioides. Barton, *Med. Bot.* ii. 165.—*Cunila pulegioides.* Willd. *Sp. Plant.* i. 122. This is an indigenous annual plant, from nine to fifteen inches high, with a small, branching, fibrous, yellowish root, and a pubescent stem, which sends off numerous slender erect branches. The leaves are opposite, oblong-lanceolate or oval, nearly acute, attenuated at the base, remotely serrate, rough or pubescent, and prominently veined on the under surface. The flowers are very small, pale-blue, supported on short peduncles, and arranged in axillary whorls along the whole length of the branches. The plant is common in all parts of the United States, preferring dry grounds, and, where abundant, scenting the air for a considerable distance with its grateful odour.

Both in the recent and dried state it has a pleasant aromatic smell, and a warm, pungent, mint-like taste. It readily imparts its virtues to boiling water. The volatile oil upon which they depend may be separated by distillation, and employed instead of the herb itself.

Medical Properties and Uses. Pennyroyal is a gently stimulant aromatic, and may be given in flatulent colic and sick stomach, or to qualify the action of other medicines. Like most of the aromatic herbs, it possesses the property, when administered in warm infusion, of promoting perspiration, and of exciting the menstrual flux when the system is predisposed to the effort. Hence it is much used as an emmenagogue in popular practice, and frequently with success. A large draught of the warm tea is given at bedtime, in recent cases of suppression of the menses, the feet having been previously bathed in warm water.

HELIANTHEMUM. *U. S. Secondary.*

Frostwort.

The herb of Helianthemum Canadense. *U. S.*

HELIANTHEMUM. *Sex. Syst.* Polyandria Monogynia. — *Nat. Ord.* Cistaceæ.

Gen. Ch. Calyx five-leaved, the two exterior sepals bract-like, smaller, or wanting. *Petals* five, rarely three, sometimes abortive. *Stigma* capitate, sometimes subsessile. *Capsule* triangular, three-valved, with the dissepiments in the middle of the valves. *Seeds* angular.

Helianthemum Canadense. Michaux, *Flor.* i. 308; Torrey & Gray, *Flor. of N. Am.* i. 151. — *Cistus Canadensis.* Willd. *Sp. Plant.* ii. 1199. The *frostwort, frost-weed,* or *rock rose,* as this plant is variously called, is an herbaceous perennial, from six to eighteen inches high, with a slender, rigid, pubescent stem, oblong, somewhat lanceolate leaves about an inch in length, and large yellow flowers, the calyx and peduncles of which, as well as the branches, are covered with a white down. The flowers which first appear are terminal, few or solitary, large, on short peduncles, with erosely emarginate petals about twice as long as the calyx. Later in the season, or on different plants, other flowers appear, very small, axillary, solitary or somewhat clustered, nearly sessile, sometimes destitute of petals, and usually wanting the two outer sepals of the calyx. The fruit is a capsule, smooth and shining, with brown, scabrous, punctate seeds. Eaton states that, in the months of November and December, he has seen hundreds of these plants sending out, near the roots, broad, thin, curved ice crystals, about an inch in breadth, which melted in the day, and were renewed in the morning. (*Manual of Botany,* 7th ed., p. 246.)

Frostwort grows in all parts of the United States, preferring dry sandy soils, and flowering in June in the Middle States.

Medical Properties and Uses. The herb has an astringent, slightly aromatic, and bitterish taste; and appears to possess tonic and astringent properties. Attention has only recently been attracted to it as a medicine. We have been told that it was first introduced into regular practice by Dr. Ives, of New Haven, Connecticut, who considered it a valuable remedy in scrofula. The late Dr. Isaac Parrish, of Philadelphia, informed us that he had employed it with much apparent benefit, as an internal remedy, in scrofulous affections of the eyes. In a pamphlet upon the frost-weed, by Dr. D. A. Tyler, published at New Haven, A. D. 1846, it is stated that *H. corymbosum* possesses similar properties, and is indiscriminately employed with *H. Canadense.* He found both useful in scrofula, diarrhœa, and secondary syphilis, and locally as a gargle in scarlatina, and a wash in prurigo. The plant has been used in the forms of powder, decoction, tincture, and syrup; and may be given freely with impunity. Dr. Tyler, however, has known the strong decoction and the extract to produce vomiting. He considers two grains of the latter as a full dose for an adult. W.

HELLEBORUS. *U. S.*

Black Hellebore.

Root of Helleborus niger. *U. S.*

Ellébore noire, *Fr.;* Schwarze Niesswurzel, *Germ.;* Elleboro nero, *Ital.;* Helebor negro, *Span.*

HELLEBORUS. *Sex. Syst.* Polyandria Polygynia. — *Nat. Ord.* Ranunculaceæ.

Gen. Ch. Calyx none. *Petals* five or more. *Nectaries* bilabiate, tubular. *Capsules* many-seeded, nearly erect. *Willd.*

Helleborus niger. Willd. *Sp. Plant.* ii. 1336; Woodv. *Med. Bot.* p. 473, t. 169; Carson, *Illust. of Med. Bot.* i. 8, pl. 1. The root or rhizoma of the black hellebore is perennial, knotted, blackish on the outside, white within, and sends off numerous long, simple, depending fibres, which are brownish-yellow when fresh, but become dark-brown upon drying. The leaves are pedate, of a deep-

green colour, and stand on long footstalks which spring immediately from the root. Each leaf is composed of five or more leaflets, one terminal, and two, three, or four on each side, supported on a single partial petiole. The leaflets are ovate-lanceolate, smooth, shining, coriaceous, and serrated in their upper portion. The flower-stem, which also rises from the root, is six or eight inches high, round, tapering, and reddish towards the base, and bears one or two large, pendent, rose-like flowers, accompanied with floral leaves, which supply the place of the calyx. The petals, five in number, are large, roundish, concave, spreading, and of a white or pale rose-colour, with occasionally a greenish tinge. There are two varieties of the plant—*humilifolius* and *altifolius*—in the former of which the leaves are shorter than the flower-stem, in the latter longer. It is a native of the mountainous regions of southern and temperate Europe, and is found in Greece, Austria, Italy, Switzerland, France, and Spain. It is cultivated in gardens for the beauty of its flowers, which expand in the middle of winter, and have thus given it the name of *Christmas rose.*

Till the publication of Tournefort's travels in the Levant, this plant was regarded as identical with the hellebore of the ancient Greeks and Romans. But in the island of Anticyra, and various parts of continental Greece, in which it appears from the testimony of ancient writers that the hellebore abounded, this traveller discovered a species entirely distinct from those before described, and particularly from *H. niger*. He called it *H. orientalis*, and reasonably inferred that it was the true hellebore of the ancients; and botanists at present generally coincide in this opinion. But, as *H. niger* is also found in some parts of Greece, it is not impossible that the two plants were indiscriminately used. It is, indeed, highly probable that they possess similar properties; and a third, *H. viridis*, which grows in the west of Europe, is said to be frequently substituted for *H. niger*, which it closely resembles, if it does not equal in medicinal power. The roots of various other plants, not belonging to the same genus, are said to be frequently substituted for the black hellebore. They may usually be readily distinguished by attending to the characters of the genuine root.*

* The following minute description of the root, which we translate from Geiger's *Handbuch der Pharmacie*, may, perhaps, be useful in enabling the druggist to distinguish this from other analogous roots, mingled with or substituted for it in commerce. "It is usually a many-headed root, with a caudex or body half an inch thick or less, seldom thicker, and several inches long, horizontal, sometimes variously contorted, uneven, knotty, with transverse ridges, slightly striated longitudinally, presenting on its upper surface the short remains of the leaf and flower stalks, and thickly beset upon the sides and under surface with fibres of the thickness of a straw, and from six to twelve inches long. These are undivided above, but, at the distance of from two to six inches from their origin, are furnished with small, slender branches. The colour of the root is dark-brown, sometimes rather light-brown, dull, and for the most part exhibiting a gray, earthy tinge. Internally it is whitish, with a somewhat darker pith, which, when cut transversely, shows lighter converging rays. Sometimes it is porous. It has a medullary or fleshy, not a ligneous consistence. The fibres, when dried, are wrinkled, very brittle, sometimes grayish internally, horny, with a white point in the centre. The odour of the dried root is feeble, somewhat like that of seneka, but more nauseous, especially when it is rubbed with water. The taste is at first sweetish, then nauseously acrid and biting, but not very durable, and slightly bitterish." (*Handbuch*, ii. *s.* 1181.)

A root said to be not unfrequently substituted for or mixed with the genuine, and often to be met with in the shops of this country, is thought to be that of the *Actæa spicata* of Europe. This has been particularly described by Dr. Carson in the *American Journal of Pharmacy* (xx. 163). The points of difference upon which that writer especially insists are the diffuse, jointed, stem-like character of the caudex of the false root, the straggling, separated, and horizontal arrangement of the fibres, and their dense, woody structure, and reddish-brown colour, contrasted with the thickness, double-headed form, and sponginess of the genuine caudex, the close-set, perpendicular position of its fibres, and their wrinkled appearance, soft texture, and grayish-brown colour. The transverse section of the fibre of the Actæa presents the appearance of a cross, which is not obvious in that of the black hellebore, though the central point of this, if closely examined, will be found to present a somewhat stellate appearance. In the *Pharm. Journ. and Trans.* for Aug. 1861 (p. 112), Prof. Bentley states that solution of perchloride of iron produces little change of colour and little or no precipitation with an infusion of black hellebore, while, with a similar infusion of the Actæa root, it causes a deep-blue or black colour and a copious precipitate.

The medicine of which we are treating is sometimes called *melampodium*, in honour of Melampus, an ancient shepherd or physician, who is said to have cured the daughters of King Prætus by giving them the milk of goats which had been fed on hellebore.

Properties. Though the whole root is kept in the shops, the fibres are the portion usually recommended. They are about as thick as a straw, when not broken from four inches to a foot in length, smooth, brittle, externally black or deep brown, internally white or yellowish white, with little smell, and a bitterish, nauseous, acrid taste. In their recent state they are extremely acrimonious, producing on the tongue a burning and benumbing impression, like that which results from taking hot liquids into the mouth. This acrimony is diminished by drying, and still further impaired by age. MM. Feneulle and Capron obtained from black hellebore a volatile oil, an acrid fixed oil, a resinous substance, wax, a volatile acid, bitter extractive, gum, albumen, gallate of potassa, supergallate of lime, a salt of ammonia, and woody fibre. Mr. William Bastick discovered a peculiar crystalline principle, which he proposed to call *helleborin*. It was obtained by diluting with water a strong tincture of the root, expelling the alcohol by heat, filtering to separate the resin, adding carbonate of potassa in excess, and agitating the mixture with three or four times its volume of ether. The ethereal solution was separated, and on evaporation yielded the helleborin, which was purified by solution in alcohol, and crystallization. It is in white, translucent crystals, of a bitter taste with a tingling effect on the tongue, not volatilizable, slightly soluble in water, more so in ether and alcohol, and more readily in these liquids hot than cold. Though nitrogenous, it is neither acid nor alkaline. It probably exists uncombined in the root. (*Pharm. Journ.*, xii. 274.) Water and alcohol extract the virtues of the root, which are impaired by long boiling.

Some interesting results, chemical and physiological, in relation to both the black and green hellebore, which in these respects may be considered as one, have been obtained by Marme and Husemann. A solution of an extract of the root, having been purified by precipitation with solution of subacetate of lead, and then freed from lead by sulphuretted hydrogen, yielded with phospho-molybdic acid a precipitate, which was found to have poisonous properties. Unfortunately, they gave to this principle the name of *helleborin*, which had been already appropriated by Mr. Bastick. They ascertained that it was a glucoside, separable by boiling with acid into glucose and a peculiar principle which they propose to call *helleboretin*. The helleborin of these chemists exists both in the root and leaves. It has a taste at once sweet and bitter, is soluble in water and weak alcohol, and much less so in ether and absolute alcohol, and is crystallizable in rhomboidal prisms. It is precipitable by tannic acid and the protacetate of mercury. (*Journ. de Pharm. et de Chim*, 4e sér., ii. 258.) In the *American Journ. of Pharm.* (May, 1866, p. 247), quoting from the *Druggists' Circular*, an account is given of a second glucoside obtained by the same chemists from the same source, which they distinguish by the name of *helleborein;* but the mode of its preparation, and its precise chemical properties, are not given. May it not be the helleborin of Bastick? Though both the principles referred to by the German chemists mentioned are poisonous, the products of their decomposition are said to be harmless. Neither of them is volatile. Helleborein is strongly irritant to the mucous membranes, causing, when applied to the conjunctiva, redness, swelling, and increased secretion with indirect enlargement of the pupil, and to the nasal membrane, sneezing, though in less degree than veratria. The salivary secretion appears to be stimulated not only by its application to the mouth, but also through the system. Small doses produce little effect on the stomach; but, repeated and accumulated, they cause anorexia, nausea even to vomiting, pain, increased secretion, and inflammation both of the stomach and bowels. The kidneys and generative organs in women are also stimulated. In very small doses, it lessens the frequency of the pulse; but in large doses, it accelerates the circulation, often even fatally. Gradual paralysis and convulsions are among its poisonous effects. The *helleborin* of Marme

and Husemann is a more active poison, though less irritant to the mucous membrane. It acts on the tongue like aconite. Its action appears to be directed especially to the nervous system. In the lower animals it causes quickened breathing, restlessness, tension and trembling of the muscles, uncertainty of movement; then retardation of the breathing and pulse, irritability of the peripheral nerves, dilatation of the pupil, loss of hearing, and finally almost complete anæsthesia, with cerebral and spinal congestion, even to apoplexy.

Medical Properties and Uses. Black hellebore is a drastic hydragogue cathartic, possessed of emmenagogue powers, which by some are ascribed to a specific tendency to the uterus, by others are supposed to depend solely on the purgative property. In overdoses it produces inflammation of the gastric and intestinal mucous membrane, with violent vomiting, hypercatharsis, vertigo, cramp, and convulsions, which sometimes end in death. The fresh root applied to the skin produces inflammation and even vesication. The medicine was very highly esteemed by the ancients, who employed it in mania, melancholy, amenorrhœa, dropsy, epilepsy, various cutaneous affections, and verminose diseases. By the earlier modern physicians it was also much used. *Bacher's pills*, celebrated for the cure of dropsy, consisted chiefly of black hellebore. It is at present little employed except as an emmenagogue, in which capacity it is highly esteemed by some practitioners. Dr. Meade considered it superior to all other medicines belonging to this class. It may be given in substance, extract, decoction, or tincture. The dose of the powdered root is from ten to twenty grains as a drastic purge, two or three grains as an alterative. The decoction is prepared by boiling two drachms in a pint of water, of which a fluidounce may be given every four hours till it operates. The extract and tincture are officinal.

HEMIDESMI RADIX. *Br.*

Hemidesmus Root. Indian Sarsaparilla.

The dried root of Hemidesmus indicus. *Br.*

Hemidesmus. *Sex. Syst.* Pentandria Digynia. — *Nat. Ord.* Asclepiadaceæ.

Gen. Ch. Corolla rotate. *Filaments* connate at the base, not united above, inserted into the tube of the corolla. *Anthers* cohering separate from the stigma, with twenty pollen-masses *Stigma* flattish, pointless.

Hemidesmus Indicus. R. Brown, *Hort. Kew.* ii. 75; Lindley, *Flor. Med.* p. 543. — *Periploca Indica.* Willd. *Sp. Plant.* i. 1251. This is a climbing plant, with twining, woody, slender stems, and opposite petiolate leaves, which are entire, smooth, shining, and of a firm consistence. The leaves vary much in size and shape, some being linear and acute, others broad-lanceolate, and others again oval or ovate. The flowers are small, green on the outside, purple within, and disposed in axillary racemes. The calyx is five-parted, with acute divisions; the corolla flat, with oblong, pointed divisions. The fruit consists of two long, slender, spreading follicles.

This plant is common over the whole peninsula of Hindostan. The officinal portion is the root, which has long been used in India as a substitute for sarsaparilla. It is long, slender, tortuous, cylindrical, and little branched, consisting of a ligneous centre, and a brownish, corky bark, marked with longitudinal furrows and transverse fissures. It has an aromatic odour and bitter taste. Mr. Garden obtained from it a peculiar volatilizable acid principle, which he named *smilasperic acid*, under the erroneous impression that the root was derived from *Smilax aspera.* Pereira proposed to call it *hemidesmic acid.*

Medical Properties and Uses. Indian sarsaparilla is said to be tonic, diuretic, and alterative. It was introduced into Great Britain from India, and was employed for some time under the name of *smilax aspera.* It is used for the same purposes as sarsaparilla. In some instances it is said to have proved successful in syphilis when that medicine had failed; but it cannot be relied on. The na-

tive practitioners in India are said to employ it in nephritic complaints, and in the sore-mouth of children. It is used in the form of infusion or decoction, made in the proportion of two ounces of the root to a pint of water. A pint may be given, in wineglassful doses, in the course of the day. A syrup is directed in the British Pharmacopœia. (See *Syrupus Hemidesmi.*)

HEPATICA. *U. S. Secondary.*

Liverwort.

The leaves of Hepatica Americana. *U. S.*

Hepatica. *Sex. Syst.* Polyandria Polygynia. — *Nat. Ord.* Ranunculaceæ.

Gen. Ch. Calyx three-leaved. *Petals* six to nine. *Seeds* naked. *Nuttall.*

Hepatica Americana. De Cand.; Eaton, *Manual of Botany*, p. 241. — *H. triloba.* Willd. *Enum.;* figured in Rafinesque's *Med. Flor.* i. 238. Botanists generally admit but one species of Hepatica, *H. triloba*, and consider as accidental the difference of structure and colour observable in the plant. Pursh speaks of two varieties, one with the lobes of the leaf oval and acute, the other with the lobes rounded and obtuse. These are considered as distinct species by De Candolle, and the latter is the one adopted by the Pharmacopœia, and popularly employed as a medicine in this country, under the name of *liverwort.* Both have a perennial fibrous root, with three-lobed leaves, cordate at their base, coriaceous, nearly smooth, glaucous and purplish beneath, and supported upon hairy footstalks from four to eight inches long, which spring directly from the root. The scapes or flower-stems are several in number, of the same length with the petioles, round, hairy, and terminating in a single white, bluish, or purplish flower. The calyx is at a little distance below the corolla, and is considered by some an involucre, while the corolla takes the name of the calyx. In *H. acutiloba* the leaves are cordate, with from three to five entire, acute lobes; and the leaflets of the calyx are acute. In *H. Americana* the leaves are cordate-reniform, with three entire, roundish, obtuse lobes; and the leaflets of the calyx are obtuse. Both are indigenous, growing in woods upon the sides of hills and mountains; the former, according to Eaton, preferring the northern, the latter the southern exposure. The leaves resist the cold of the winter, and the flowers make their appearance early in spring. The whole plant is used.

It is without smell, and has a mucilaginous, somewhat astringent, slightly bitterish taste. Water extracts all its active properties.

Medical Properties and Uses. Liverwort is a very mild, demulcent tonic and astringent, supposed by some to possess diuretic and deobstruent virtues. It was formerly used in Europe in various complaints, especially chronic hepatic affections, but has fallen into entire neglect. In this country some years since, it acquired considerable popular reputation, which, however, it has not maintained, as a remedy in hæmoptysis and chronic coughs. It may be used in infusion, and taken ad libitum. The term *liverwort* properly belongs to the cryptogamous genus *Marchantia.* W.

HEUCHERA. *U. S. Secondary.*

Alum-root.

The root of Heuchera Americana. *U. S.*

Heuchera. *Sex. Syst.* Pentandria Digynia. — *Nat. Ord.* Saxifragaceæ.

Gen. Ch. Calyx five-cleft. *Petals* five, small. *Capsule* bi-rostrate, bi-locular, many-seeded. *Nuttall.*

Heuchera Americana. Willd. *Sp. Plant.* i. 1328; Barton, *Med. Bot.* ii. 159. — *H. cortusa.* Michaux, *Flor. Boreal. Am.* i. 171. — *H. viscida.* Pursh, *Flor. Am. Sept.* p. 187. The *alum-root* or *American sanicle* is a perennial, herbaceous plant, the leaves of which are all radical, petiolate, cordate, with rounded

lobes, furnished with obtuse mucronate teeth. There is no proper stem; but numerous scapes or flower-stems are sent up by the same root, from one to three feet in height, very hairy in their upper part, and terminating in long, loose, pyramidal, dichotomous panicles. The calyx is small, with obtuse segments; the petals lanceolate, rose-coloured, and of the same length as the calyx; the filaments much longer, yellowish, and surmounted by small, red, globose anthers The whole plant is covered with a viscid pubescence.

It is found in shady, rocky situations, from New England to Carolina, and flowers in June and July. The root, which is officinal, is horizontal, somewhat compressed, knotty, irregular, yellowish, and of a strongly styptic taste.

Medical Properties. Alum-root is powerfully astringent, and may be employed in similar cases with other medicines belonging to the same class. It has hitherto, however, been little used. We are informed, in Dr. Barton's "Collections," that it is applied by the Indians to wounds and obstinate ulcers, and that it is the basis of a powder which, when the author wrote, enjoyed some reputation as a cure for cancer. Mr. Frederick Stearns, in a report to the Am. Pharmaceutical Association in reference to the medicinal plants of Michigan (*Proceedings*, A. D. 1858, p. 263), speaks of two other species, *H. caulescens* and *H. pubescens*, as having similar properties. W

HIRUDO. *Br.*

The Leech.

Sanguisuga medicinalis, the *Speckled Leech;* and S. officinalis, the *Green Leech, Br.*

Sangsue, *Fr.;* Blutegel, *Germ.;* Mignátta, *Ital.;* Sanguijuela, *Span.*

Hirudo. *Class* 1, Annelides. *Order* 3, Abranchiatæ. *Family* 2, Asetigeræ. *Cuvier.*

The leech belongs to that class of invertebrated articulated animals called *Annelides.* This class contains the worms with red blood, having soft retractile bodies composed of numerous segments or rings, breathing generally by means of branchiæ, with a nervous system consisting in a double knotted cord, destitute of feet, and supplying their place by the contractile power of their segments or rings. The third order of this class—*Abranchiatæ*—comprehends those worms which have no apparent external organ of respiration. This order is again divided into two families, to the second of which—the *Asetigeræ*, or those not having setæ to enable them to crawl—the leech belongs.

It is an aquatic worm with a flattened body, tapering towards each end, and terminating in circular flattened disks, the hinder one being the larger of the two. It swims with a vertical undulating motion, and moves when out of the water by means of these disks or suckers, fastening itself first by one and then by the other, and alternately stretching out and contracting its body. The mouth is placed in the centre of the anterior disk, and is furnished with three cartilaginous lens-shaped jaws at the entrance of the alimentary canal. These jaws are lined at their edges with fine sharp teeth, and meet so as to make a triangular incision in the flesh. The head is furnished with small raised points, supposed by some to be eyes. Respiration is carried on through small apertures ranged along the inferior surface. The nervous system consists of a cord extending the whole length, furnished with numerous ganglions. The intestinal canal is straight, and terminates in the anus, near the posterior disk. Although hermaphrodite, leeches mutually impregnate each other. They are oviparous, and the eggs, varying from six to fifteen, are contained in a sort of spongy, slimy cocoon, from half an inch to an inch in diameter. These are deposited near the edge of the water, and hatched by the heat of the sun. The leech is torpid during the winter, and casts off from time to time a thick slimy coating from its skin. It can live a considerable time in sphagnous moss, or in moistened earth, and is frequently transported in this manner to great distances by the dealers.

Savigny has divided the genus Hirudo of Linnæus into several genera. The

true leech is the Sanguisuga of this author, and is characterized by its three lenticular jaws, each armed with two rows of teeth, and by having ten ocular points. Several species are used for medical purposes, of which the most common are the gray and the green leech of Europe, both of which are varieties of the *Hirudo medicinalis* of Linnæus; and the *Hirudo decora* of this country.

1. *Hirudo medicinalis.* Linn. *Ed. Gmel.* i. 3095. — *Sanguisuga officinalis.* Savigny, *Mon. Hir.* p. 112, t. 5, f. 1. *The green leech.* — *Sanguisuga medicinalis.* Savigny, *Mon. Hir.* p. 114, t. 5, f. 2. *The gray leech.* Many of the best zoologists regard the *Sanguisuga officinalis* and *S. medicinalis* of Savigny as mere varieties. They are both marked with six longitudinal dorsal ferruginous stripes, the four lateral ones being interrupted or tesselated with black spots. The colour of the black varies from a blackish to a grayish-green. The belly in the first variety is of a yellowish-green colour, free from spots, and bordered with longitudinal black stripes. In the second it is of a green colour, bordered and maculated with black. This leech varies from two to four inches in length. It inhabits marshes and running streams, and is abundant throughout Europe.*

The great use made of leeches in the modern practice of medicine has occasioned them to become a considerable article of commerce. They are collected in Spain, France, Italy, Germany, and Sweden, and carried in large numbers to London and Paris. They are also frequently brought to this country; as the practitioners in some of our large cities use only the foreign leech, although our own waters furnish an inexhaustible supply of this useful worm.†

2. *Hirudo decora.* Say, *Colonel Long's Second Expedition*, ii. 268. The medicinal leech of America has been described by Say under the name of *Hirudo decora*, in the Appendix to the Second Expedition of Colonel Long. Its back is of a deep pistachio-green colour, with three longitudinal rows of square spots. These spots are placed on every fifth ring, and are twenty-two in number. The lateral rows of spots are black, and the middle range, of a light brownish-orange colour. The belly is of the latter colour, variously and irregularly spotted with black. The American leech sometimes attains the length of four or five inches, although its usual length is from two to three. It does not make so large and deep an incision as the European leech, and draws less blood.

The indigenous leech is much used in the city of Philadelphia. The practi-

* A variety of the leech has recently come into use in Europe, called in commerce *African leeches*. They are of a beautiful light-green colour, varying to a deep-green, and often inclining to red, with black points on the back, and broad streaks of a bright orange-yellow, which are black towards the abdomen. They correspond perfectly with the *Sanguisuga interrupta* of Moquin-Tandon. These leeches draw very well. (*Pharm. Journ.*, x. 38, from *Buchner's Repertorium*, A. D. 1850, p. 376.) The leeches from Algiers, called in French commerce *dragons* (*Sanguisuga troctena* of Moquin-Tandon), of which considerable numbers have been taken to France, are said by M. A. de Quatrefages, contrary to former opinion, to be quite equal to the European. (*Journ. de Pharm.*, 3e sér., xxxiii. 105.) It is stated in the *Pharmaceutical Journal and Transactions* (June, 1867, p. 735) that great numbers of leeches are collected in Australia, and sent to Melbourne, whence a large proportion are exported to Europe and America, chiefly to London and Paris in the former continent, and San Francisco, Panama, and New York in the latter. It is estimated that two or three millions annually pass through the hands of the Murray River Fishing Company. In the same journal (March, 1865, p. 481), the leech is said to abound in almost every river and lagoon in Australia, and to differ from the ordinary English leech only, that the olive streaks are much lighter in the former. They are collected by throwing into the water a fresh sheep-skin, to which they attach themselves. They bear transportation wonderfully well. (*Note to the ninth, twelfth, and thirteenth editions.*) W.

† Attempts have been made, in France, on a large scale, to propagate leeches for sale. This is done by means of natural meadows, in which numerous small ponds are made, where the leeches, with certain precautions as to nourishment and preservation, multiply and grow so rapidly as to become a source of profit. In order that they may propagate, it is necessary that they should be fed on blood, which is given them either by causing animals, as horses, cows, &c., to be driven into the meadows, or by obtaining blood from slaughter-houses, and, after depriving it of fibrin by agitation, immersing the animals for a time in it while yet warm. For very interesting particulars in relation to this kind of culture, the reader is referred to papers in the *Journ. de Pharm.* (Jan 1854 p. 5, and Mai, 1854, p. 336).—*Note to the eleventh edition.* W.

tioners of New York and Boston are supplied chiefly from abroad. The leeches employed in Philadelphia are generally brought from Bucks and Berks counties, in Pennsylvania, and occasionally from other parts of the State.

The proper preservation of leeches is an object of importance to the practitioner, as they are liable to a great and sudden mortality. They are usually kept in jars, in clear, soft water, which should be changed twice a week in winter, and every other day in summer. The jar must be covered with a linen cloth, and placed in a situation not liable to sudden changes of temperature. They will live a long time and continue active and healthy, without any other attention than that of frequently changing the water in which they are kept. M. Derheims has proposed the following excellent method of preserving them. In the bottom of a large basin or trough of marble he places a bed, six or seven inches deep, of a mixture of moss, turf, and fragments of wood. He strews pebbles above, so as to retain them in their place without compressing them too much, or preventing the water from freely penetrating them. At one end of the trough, and about midway of its height, is placed a thin slab of marble or earthenware, pierced with numerous holes, and covered with a bed of moss, which is compressed by a thick layer of pebbles. The reservoir being thus disposed is half filled with water, so that the moss and pebbles on the shelf shall be kept constantly moist. The basin is protected from the light by a linen cover stretched over it. By this arrangement the natural habits of the leech are not counteracted. One of these habits, essential to its health, is that of drawing itself through the moss and roots to clear its body from the slimy coat which forms on its skin and is a principal cause of its disease and death. Mr. James Banes recommends that, when kept in jars, they should be cleansed by means of a whisk of very fine broom or willow, when the water is changed. M. Lahache, an apothecary at Bruyères, strongly recommends the carrageen or Irish moss (*Chondrus crispus*), as admirably adapted to the habits and wants of the leech, furnishing the animal, as he supposes, with nutriment, as it does not die of inanition when thus kept. The water should be renewed in the jars daily. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 128.)*

* M. Soubeiran considers it important that they should be kept in running water, and has figured an apparatus for this purpose in the second edition of his Treatise on Pharmacy. The addition of a solution of chlorine to the water, in the proportion of one or two drops to the pint, or of a little muriatic or sulphuric acid to neutralize the ammonia which forms, has sometimes been found a preservative against disease. (*Journ. de Pharm.*, 3e sér., x. 186.) M. Domine has found the following plan for preserving leeches most successful. He selects the greenest moss he can find, washes it perfectly clean, and puts alternately it and the leeches, also well washed, into a glass vessel of convenient size, taking care to fill the vessel completely with the loosened moss, and then to cover it with a piece of linen. In winter, it is sufficient merely to introduce the leeches and moss moistened; but, as soon as warm weather approaches, a little water should be put at the bottom of the vessel. It is not necessary to change often in winter; but in summer the moss should be renewed nearly every other day, and the vessel should be kept in the cellar. (*Ibid.*, xvi. 110.)—*Note to the ninth edition.* W.

Mr. Alfred Allchin has had great success in the preservation of leeches by the use of *aquaria*, in which the natural conditions necessary for the health of the animal are supplied, by introducing a living and growing water plant, to afford oxygen and consume carbonic acid, and water snails to consume the decaying vegetable matter, the confervæ which grow on the sides of the vessel, and the slimy matter given off by the leeches themselves. For full particulars in relation to the structure and management of these aquaria, the reader is referred to the *Am. Journ. of Pharm.* (xxviii. 222), and the *Pharm. Journ.* (xv. 453), in the latter of which journals the account was originally published. (*Note to the eleventh edition.*) W.

An interesting account of the culture of both the Spanish and American leech (the latter H. decora) has been published in the "*Proceedings of the American Pharmaceutical Association" for the year* 1857, by Mr. Frederick Stearns, of which the following is an epitome. A wooden tank, eight feet in length by six in breadth and four in depth, is placed in the ground, near a running stream, so that a portion of the water passes through it, the orifices through which it enters and escapes being covered with wire-gauze to prevent the exit of the animal. A layer of cobble stones eighteen inches thick is placed in the bottom of the tank. The outlet is about ten inches below the top of the tank, and from the edge at top, all round, a ledge of boards is made to project inward. A few frogs are thrown in once a week for food. In winter the animal is torpid, and the tank

Medical Uses. Leeches afford the least painful, and in many instances the most effectual means for the local abstraction of blood. They are often applicable to parts which, either from their situation or their great tenderness when inflamed, do not admit of the use of cups; and, in the cases of infants, are under all circumstances preferable to that instrument. They are indeed a powerful therapeutic agent, and give to the physician, in many instances, a control over disease which he could obtain in no other way. Their use is in great measure restricted to the treatment of local inflammation; and, as a general rule, they should not be resorted to until the force of the circulation has been diminished by bleeding from the arm, or in the natural progress of the complaint.

In applying leeches to the skin, care should be taken to shave off the hair, if there be any, and to have the part well cleansed with soap and water, and afterwards with pure water. If the leech do not bite readily, the skin should be moistened with a little blood, or milk and water. It is said to bite more freely if the skin is previously reddened by a sinapism, and then washed perfectly clean. Sometimes the leech is put into a large quill open at both ends, and applied with the head to the skin until it fastens itself, when the quill is withdrawn. If it be desirable that the leech shall bite in a particular spot, this end may be attained by cutting a small hole in a piece of blotting-paper, and then applying this moistened to the skin, so that the hole shall be immediately over the spot from which the blood is to be taken. Leeches continue to draw blood until they are gorged, when they drop off * The quantity of blood which they draw varies with the part to which they are applied, and the degree of inflammation existing in it. From the loose and vascular textures they will abstract more than from those which are firm and compact, and more from an inflamed than a healthy part. As a general rule, our leechers apply six for every fluidounce of blood. A single European leech will draw from half an ounce to an ounce. The quantity may often be much increased by bathing the wound with warm water. Leeches will continue to suck after their tails are cut off, which is sometimes done, although it is a barbarous practice.† It is said that they will draw better if put into cold beer, or diluted wine, and allowed to remain until they become very lively. They may be separated from the skin at any time by sprinkling a little salt upon them. After they drop off, the same application will make them disgorge the blood they have swallowed. Some leechers draw the leeches from the tail to the head through their fingers, and thus squeeze out the blood, after which all that is necessary is to put them in clean water, and change it frequently.‡ Leeches

is allowed to remain frozen over till spring. The eggs are produced in June and July; the leech is mature in about two years, and will live fifteen. (*Note to the twelfth edition.*) W.

* As a very efficient mode of applying leeches, it is recommended, after having moistened the skin with pure warm water, to put the leeches into a tumbler half full of cold water, and by an adroit movement invert it upon the part. The leeches are said to attach themselves so rapidly that it seems to the patient as though they made but a single bite. When they are all attached, the glass is to be carefully removed, the water being absorbed, as it runs off on one side, by a sponge or linen cloths.

Another method of increasing the efficiency of leeches, recommended by Dr. C. R. Sloan, of Ayr, Scotland, is to cover them with a cupping-glass, and, by means of an air-pump, moderately exhaust the air over them. An extraordinary increase in their activity is immediately observable. (*Ed. Monthly Journ. of Med. Sci.*, Aug. 1852, p. 126.) W.

† Under the name of *bdellatomy*, a practice has been introduced into Germany, of making a small incision in the side of the leech while drawing. The blood escapes through the wound, and the animal will continue to suck for a long time, so that one will perform the office of many in the quantity of blood taken. It is asserted that the operation causes little or no pain, but is in fact a source of gratification by prolonging the pleasure of taking food. Some years since, the author received a communication on the subject from the originator of the process; but he regrets that it has been mislaid, and he cannot give the name, as he would desire. (*Note to the thirteenth edition.*) W.

‡ MM. Soubeiran and Bouchardat, after numerous experiments upon the different modes of fitting the gorged leeches for use again, came to the conclusion, that a carefully managed pressure is the best. Two conditions, however, are necessary to success; one that they should be disposed to disgorge the blood, and the other that they should be immersed in warm water previously to the stripping. The first object is effected by com-

which are gorged with blood should be kept in a vessel by themselves; as they are more subject to disease, and often occasion a great mortality among the others. They should not be again used until they have recovered their activity. In cases where the bleeding from leech-bites continues longer than is desirable, it may be stopped by continued pressure, with the application of lint, by the use of collodium, or by touching the wounds with lunar caustic.* It may sometimes be necessary, in the case of a deep bite, to sew the wound, which is readily done with a single stitch of the needle, that need not penetrate deeper than the cutis.†

D. B. S.

mon salt. The following plan is recommended. The leeches are to be thrown into a solution of 16 parts of common salt in 100 of water, from which they are to be taken out one by one, and, being held by the tail, are to be dipped into water which feels hot to the hand, but yet can be borne by it, and then passed lightly between the fingers. Thus treated, they easily give up the blood. After being stripped, they should be placed in vessels containing fresh water, which should be renewed once a day. At the end of eight or ten days, they are fit for reapplication. (*Journ. de Pharm.*, 3e sér., xi. 343 and 350.) It is said that, in the French military hospitals, a mixture of vinegar and water, consisting of one part of the former to eight of the latter, is preferred to salt water for promoting disgorgement. (*Lond. Med. Times and Gaz.*, Oct. 1856, p. 375.)

It has been stated that, if the leeches, after being stripped, be put into water sweetened with a little white sugar, and the solution be renewed several times, at intervals of six or twelve hours, they will speedily recover their activity, and may be reapplied two or three times in the course of a few days. Immersion in camphor water, for a few moments, is said by Mr. Boyce to cause them to vomit the blood. They should afterwards be put into clean water, to be changed in half an hour. Dr. Frodsham, of England, has found camphor water preferable either to salt water or diluted vinegar, for disposing the gorged leech to part with blood.

M. Grannat, a French military pharmaceutist, has found the natural process of disgorging preferable to all others. He placed some gorged leeches in wooden tubs, containing at bottom a little clay and water, and renewed the water every forty-eight hours. After eight days, the leeches, now in good health, were transferred to a pond prepared for the purpose, where they propagated. He put 1000 leeches in the pond, and at the end of a year had taken out 850 fit for service, without interfering with the reproduction. (*Journ. de Pharm.*, 3e sér., xx. 186.)

M. Vayson's plan of preserving leeches has been highly commended. It consists simply in putting them, after stripping, if they have been used, in an earthenware vessel of the shape of an inverted truncated cone, with holes in the bottom so small as to prevent the escape of the leech, and filled with turfy earth. After the introduction of the leech the opening is to be closed with a coarse cloth. The vessel is then placed in a tub containing water four inches deep. If to be sent to a distance, the earth in the vessel should be moistened throughout. W.

* A little cotton, impregnated with a saturated solution of alum in boiling-hot water, and, after it has become sufficiently cool, but before the alum has begun to crystallize, pressed upon the wound, will often prove effectual. Another mode of repressing the hemorrhage is to press upon the bite a piece of thin caoutchouc, previously softened upon one side by heat, so as to become adhesive. If lunar caustic be applied, the stick must first be brought to a fine point, which is to be inserted in the wound. Some have even recommended the use of a fine wire made red hot. When the part wounded is without a bony basis, pressure may be made by pinching the wound between the fingers. W.

† An instrument has been invented called the *mechanical leech*, by which the attempt has been made to imitate the action of the leech in drawing blood. It consists essentially of two parts, one for making the puncture, and the other for abstracting blood through the agency of atmospheric pressure. In other words, it is a minute cupping instrument. Practically, however, it has not been found so convenient as to supersede the use of the living leech. For an account of the instrument, see the *Am. Journ. of the Med. Sciences* (xvi. 207). W.

Danger from Leeches. Young leeches are sometimes swallowed by men and animals while drinking from streams or ponds inhabited by them. If swallowed they probably perish in the stomach; but occasionally they attach themselves in the passages, in man most frequently to the fauces or pharynx, but in the lower animals also to the gums, cheeks, soft palate, and even the nasal passages. The animal has been known to attach itself within the larynx, with the most alarming effects. It grows in its new quarters, living on the blood which it draws, much of which also escapes from the punctures, causing spitting of blood, which probably first calls attention to the case. There are also various morbid sensations, such as arise from the presence of a foreign body in the throat, and symptoms of impending suffocation when the animal is near the glottis. Death has occurred from this cause. Generally there is little danger, and anemic symptoms are the most

HORDEUM. *U.S.*

Barley. Pearl Barley.

The decorticated seed of Hordeum distichon. *U.S.*

Off. Syn HORDEUM DECORTICATUM. *Pearl Barley.* The husked seeds of Hordeum distichon. *Br.*

Orge, *Fr.*; Gerstengraupen, *Germ.*; Orzo, *Ital.*; Cebada, *Span.*

HORDEUM. *Sex. Syst.* Triandria Digynia. — *Nat. Ord.* Graminaceæ.

Gen. Ch. Calyx lateral, two-valved, one-flowered, three-fold. *Willd.*

Several species of Hordeum are cultivated in different parts of the world. The most common are *H. vulgare* and *H. distichon*, both of which have been introduced into the United States.

1. *Hordeum vulgare.* Willd. *Sp. Plant.* i. 472; Loudon's *Encyc. of Plants*, p. 73. The culm or stalk of common barley is from two to four feet in height, fistular, and furnished with alternate, sheathing, lanceolate, roughish and pointed leaves. The flowers are all perfect, and arranged in a close terminal spike, the axis of which is dentate, and on each tooth supports three sessile flowers. The calyx or outer chaff has two valves The corolla or inner chaff is also composed of two valves, of which the interior is larger than the other, and terminates in a long, rough, serrated awn or beard. The seeds are arranged in four rows.

2. *H. distichon.* Willd. *Sp. Plant.* i. 473; Loudon's *Encyc. of Plants*, p. 73. This species is distinguished by its flat spike or ear, which on each flat side has a double row of imperfect or male florets without beards, and on each edge, a single row of bearded perfect or hermaphrodite florets. The seeds, therefore, are in two rows, as indicated by the specific name of the plant.

The original country of the cultivated barley is unknown. The plant has been found growing wild in Sicily, and various parts of the interior of Asia. *H. vulgare* is said by Pursh to grow in some parts of the United States, apparently in a wild state. The seeds are used in various forms.

1. In their natural state they are oval, oblong, pointed at one end, obtuse at the other, marked with a longitudinal furrow, of a yellowish colour externally, white within, having a faint odour when in mass, and a mild sweetish taste. They contain, according to Proust, in 100 parts, 32 of starch, 3 of gluten, 5 of sugar, 4 of gum, 1 of yellow resin, and 55 of *hordein*, a principle closely analogous to lignin. Berzelius suggests that hordein may be an intimate mixture of vegetable fibre with gluten and starch, which are very difficultly separable as they exist in this grain. Einhoff found in 100 parts 67·18 of starch, 5·21 of uncrystallizable sugar, 4·62 of gum, 3·52 of gluten, 1·15 of albumen, 0·24 of phosphate of lime, and 7·29 of vegetable fibre; the remainder being water and loss.

2. *Malt* consists of the seeds made to germinate by warmth and moisture, and then baked so as to deprive them of vitality. By this process the sugar, starch, and gum are increased at the expense of the *hordein*, as shown by the analysis of Proust, who found in 100 parts of malt, 56 of starch, 1 of gluten, 15 of sugar, 15 of gum, 1 of yellow resin, and only 12 of *hordein*. Berzelius attributes the diminution of the hordein to the separation, during germination, of the gluten or starch from the fibrous matter with which he supposes them to be associated in that substance. It is in the form of malt that barley is so largely consumed in the manufacture of malt liquors.

An interesting substance, called *diastase*, was discovered by MM. Payen and Persoz in the seeds of barley, oats, and wheat, and in the potato. It is found, however, only after germination, in which process the production of it appears to be the first step. Germinated barley seldom contains it in larger proportion

serious of those existing. The animal can generally be seen when in the fauces, and may be removed by seizing it with an instrument. If it cannot be seized, or if invisible, as in the nares, it should be attacked by solution of salt or vinegar, which will cause it to give up its hold. Emetics have been recommended, and in one instance laryngotomy was performed. (See *Archives Gén.*, Août, 1863, p. 161.)—*Note to the twelfth edition.* W.

than two parts in a thousand. It is obtained by bruising freshly germinated barley, adding about half its weight of water, expressing strongly, treating the viscid liquid thus obtained with sufficient alcohol to destroy its viscidity, then separating the coagulated albumen, and adding a fresh portion of alcohol, which precipitates the diastase in an impure state. To render it pure, it must be redissolved as often as three times in water, and precipitated by alcohol. It is solid, white, tasteless, soluble in water and weak alcohol, but insoluble in the latter fluid when concentrated. Though without action upon gum and sugar, it has the extraordinary property, when mixed, in the proportion of only one part to 2000, with starch suspended in water, and maintained at a temperature of about 160°, of converting that principle into dextrin and sugar of grapes. The whole of the starch undergoes this change, except the teguments of the granules, amounting to about 4 parts in 1000. The change which barley undergoes during germination, and in malting, is of a similar character.

3. *Hulled barley* is merely the grain deprived of its husk, which, according to Einhoff, amounts to 18·75 parts in the hundred.*

4. *Barley meal* is formed by grinding the seeds, previously deprived of their husk. It has a grayish-white colour, and contains, according to Fourcroy and Vauquelin, an oleaginous substance, sugar, starch, azotized matter, acetic acid, phosphates of lime and magnesia, silica, and iron. It may be made into a coarse, heavy, hard bread, which in some countries is much used for food.

5. *Pearl barley* (*hordeum perlatum*) is the seed deprived of all its investments, and afterwards rounded and polished in a mill. It is in small round or oval grains, having the remains of the longitudinal furrow of the seeds, and of a pearly whiteness. It is wholly destitute of hordein, and abounds in starch, with some gluten, sugar, and gum. This is the proper officinal form of barley, and is kept in the shops almost to the exclusion of the others.

Medical Properties. Barley is one of the mildest and least irritating of farinaceous substances; and, though not medically used in its solid state, forms, by decoction with water, a drink admirably adapted to febrile and inflammatory complaints, and much employed from the time of Hippocrates to the present. Pearl barley is the form usually preferred for the preparation of the decoction, though the hulled grain is sometimes used, and malt affords a liquor more demulcent and nutritious. (See *Decoctum Hordei.*) The decoction of malt may be prepared by boiling from two to four ounces in a quart of water and straining. When hops are added, the decoction takes the name of wort, and acquires tonic properties, which render it useful in debility, especially when attended with suppuration.

* M. Lemoine, a French pharmaceutist, proposes a chemical method of decorticating barley and other seeds. Putting 100 parts of the seeds into a wooden vessel, he pours upon them 15 parts of sulphuric acid, stirs the mixture for 15 or 20 minutes, applying in the case of barley a gentle heat, then adds 50 parts of water, which he decants after a very few moments of constant agitation. After sufficient washing, and the neutralization of the last remains of acid by solution of carbonate of soda or potassa, he puts the grain upon a piece of cloth with large meshes stretched upon a frame, where he allows it to drain for about an hour, then transfers it to a similar cloth, and exposes it to a current of air for several days to dry. (*Journ. de Pharm.*, Mars, 1863, p. 223.)—*Note to the twelfth edition.*

obliquely spreading, entire. *Corolla* none. *Styles* two. *Seed* one, within a leafy calyx. *Willd.*

Humulus Lupulus. Willd. *Sp. Plant.* iv. 769; Bigelow, *Am. Med. Bot.* iii. 163. The root of the hop is perennial, and sends up numerous annual, angular, rough, flexible stems, which twine around neighbouring objects in a spiral direction, from left to right, and climb to a great height. The leaves are opposite, and stand upon long footstalks. The smaller are sometimes cordate; the larger have three or five lobes; all are serrate, of a deep-green colour on the upper surface, and, together with the petioles, extremely rough, with minute prickles. At the base of the footstalks are two or four smooth, ovate, reflexed stipules. The flowers are numerous, axillary, and furnished with bractes. The male flowers are yellowish-white, and arranged in panicles; the female, which grow on a separate plant, are pale-green, and disposed in solitary, peduncled aments, composed of membranous scales, ovate, acute, and tubular at the base. Each scale bears near its base, on its inner surface, two flowers, consisting of a roundish compressed germ, and two styles, with long filiform stigmas. The aments are converted into ovate membranous cones or strobiles, the scales of which contain, each, at its base, two small seeds, surrounded by a yellow, granular powder.

The hop is a native of North America and Europe. It is occasionally found growing wild in the Eastern States, and, according to Mr. Nuttall, is abundant on the banks of the Mississippi and Missouri. In parts of New England, New York, and Michigan, it is extensively cultivated, and most of the hops consumed in the United States are supplied by those districts. The part of the plant used is the fruit or strobiles. These when fully ripe are picked, dried by artificial heat, packed in bales, and sent into the market under the name of hops.

They consist of numerous thin, translucent, veined, leaf-like scales, which are of a pale greenish-yellow colour, and contain near the base two small, round, black seeds. Though brittle when quite dry, they are pulverized with great difficulty. Their odour is strong, peculiar, somewhat narcotic, and fragrant; their taste very bitter, aromatic, and slightly astringent. Their aroma, bitterness, and astringency are imparted to water by decoction; but the first-mentioned property is dissipated by long boiling. The most active part of hops is a substance formed on the surface of the scales, and, in the dried fruit, existing in the state of very small granules. This substance was called *lupulin* by the late Dr. A. W. Ives, of New York, by whom its properties were first investigated and made generally known; though it was previously noticed by Sir J. E. Smith, of England, and M. Planche, of France. The scales themselves, however, are not destitute of virtues, and contain, as shown by MM. Payen and Chevallier, the same active principles as the lupulin, though in less proportion.*

* Hops are often subjected in Germany to the fumes of burning sulphur, from the supposition that they keep better when thus treated. Besides, by being partially bleached by the process, old hops, which have suffered from time, having become darker, generally spotted, and weaker, assume a brighter appearance, as if fresher, and generally command a better price in the market. To detect the consequent presence of sulphurous acid, the brewers put a silver spoon in a mixture of hops and water, under the impression that it will produce a black stain upon the silver. But this test will answer only when applied within a fortnight after the use of the sulphur. A more delicate method is that of Dr. Heidenreich, who puts 20 or 30 cones of the hops in a flask with zinc and muriatic acid, and passes the hydrogen evolved through solution of acetate of lead. If sulphurous acid be present, sulphuretted hydrogen will be produced, which will occasion a dark precipitate with the solution. But even this plan often fails when the hops have been kept more than three or four weeks. A modification of this test has been proposed by Dr. R. Wagner. For the solution of acetate of lead used in Heidenreich's method, there is to be substituted a solution of nitroprusside of sodium, so weak as to have a very light-brown colour, to which have been added a few drops of solution of potassa. If the gas evolved contain the minutest proportion of sulphur, a violet colour will be produced when the first bubble passes into the solution; and this will by a continuance of the process become a magnificent purple. The least trace of sulphurous acid may thus be found; but, a few months after the sulphuring of hops, none at all can be detected. (*Chem. Gaz.*, April 1, 1856; from *Comptes Rendus.*)

Hops are said to be sometimes threshed in order to separate the lupulin, which is sold

Lupulina. *U. S. Lupulin.* This is obtained separate by rubbing or threshing and sifting the strobiles, of which it constitutes from one-sixth to one-tenth by weight. It is in the state of a yellowish powder, mixed with minute particles of the scales, from which it cannot be entirely freed when procured by a mechanical process. It has the peculiar flavour of hops, and appeared to MM. Lebaillif and Raspail, when examined by the microscope, to consist of globules filled with a yellow matter, resembling in this respect the pollen of vegetables; but, from the investigations of M. Personne, it would seem to be of the nature of a gland, commencing in a cell formed among those of the epidermis, and, when fully developed, secreting a resinous matter. (*Journ. de Pharm.*, 3e sér., xxvi. 242.) It is inflammable, and when moderately heated becomes somewhat adhesive. MM. Chevallier and Payen obtained from 200 parts, 105 of resin and 25 of a peculiar bitter principle, beside volatile oil, gum, traces of fixed oil, a small quantity of an azotized substance, and various salts. Dr. Ives found in 120 grains, 5 of tannin, 10 of extractive, 11 of bitter principle, 12 of wax, 36 of resin, and 46 of lignin. M. Personne found in the liquid distilled from it not only volatile oil, but also *valerianic acid.* (*Ibid.*, p. 333.) The virtues of the powder probably reside in the volatile oil and bitter principle, and are readily imparted to alcohol. By boiling in water the bitterness is extracted, but the aroma is partially driven off. The *volatile oil*, which may be obtained by distillation with water, is yellowish, of the odour of hops, of an acrid taste, and lighter than water. It was formerly supposed to be narcotic, but this is denied by Dr Wagner, who gave twenty drops of it to a rabbit, with no observable effect. (*Chem. Gaz.*, July 15, 1853.) It is said to consist of a carbohydrogen isomeric with pure oil of turpentine, and of an oxygenated oil.

The bitter principle, which has been named *lupulite* or *lupuline*, but ought to be called *humulin*, may be procured by treating with alcohol the aqueous extract of lupulin, previously mixed with a little lime, evaporating the tincture thus formed, treating the resulting extract with water, evaporating the solution, and washing the residue with ether. When pure it is yellowish or orange-yellow, inodorous at common temperatures, but of the smell of hops when heated, of the peculiar bitter taste of hops, partially soluble in water which takes up 5 per cent. of its weight, readily soluble in alcohol, almost insoluble in ether, neither acid nor alkaline in its reaction, and destitute of nitrogen. It is scarcely affected by the weak acids or alkaline solutions, or by the metallic salts. It is probably the tonic principle of the medicine.*

Hops, according to Wagner, contain from 3 to 7 per cent. of tannic acid, of the variety which precipitates the salts of iron greenish, and differing, moreover, from the tannic acid of galls in not being convertible into gallic acid, and in not having the characteristic property of the glucosides. Besides the tannin, Wagner has discovered in hops a yellow substance which appeared to him to be quercitrin. (*Pharm. Journ.*, Dec. 1859, p. 459.)

Medical Properties and Uses. Hops are tonic and moderately narcotic, and have been highly recommended in diseases of general or local debility, associated

separately. Their efficiency is thus, no doubt, greatly impaired. Hops thus treated have the scales more or less broken; and any parcel presenting this appearance may be suspected. Hops often contain a variable quantity of lupulin, in consequence of the granules of this substance separating, especially on agitation, and seeking the lower portion of the mass, which thus becomes richer, while the upper is poorer. They should always be examined in reference to the lupulin they contain, and, if nearly or quite destitute of it, should be deemed of inferior value, though not worthless. (*Note to the eleventh and twelfth editions.*)

* It is extremely doubtful whether the lupulite thus obtained is the active principle in a pure state. Dr. J. C. Lermer has recently obtained from hops a crystalline bitter principle, which he believes to have acid properties, and the composition of which is represented by the formula $C_{32}H_{25}O_7$. He obtained it by a very complex process; and it is, perhaps, somewhat doubtful whether it may not be a product of the operation rather than an educt; especially as he has found two other crystalline bitter principles, which he was still investigating. (See *Am. Journ. of Pharm.*, Nov. 1863, p. 540.)—*Note to the twelfth edition.*

with morbid vigilance, or other nervous derangement. They have some tendency to produce sleep and relieve pain, and may be used for these purposes in cases where opiates, from their disposition to constipate, or other cause, are inadmissible. Diuretic properties have also been ascribed to them, but are by no means very obvious. The complaints in which they have been found most useful are dyspepsia, and the nervous tremors, wakefulness, and delirium of drunkards. Dr. Maton found the extract advantageous in allaying the pain of articular rheumatism. Dr. W. Y. Godberry, of Benton, Miss., has found hops efficacious in intermittents, and considers them inferior in antiperiodic powers only to quinia. (*West. Journ. of Med. and Surg.*, March, 1853.)

The medicine may be given in substance, infusion, tincture, or extract. From three to twenty grains are mentioned as the dose of the powder; but the quantity is too small to produce any decided effect; and this mode of administration is scarcely ever resorted to. An infusion, prepared with half an ounce of hops and a pint of boiling water, may be given in the dose of two fluidounces three or four times a day. In intermittents Dr. Godberry gives, in the apyrexia, a pint of the infusion made with an ounce of hops. The extract and tincture are officinal. (See *Extractum Lupuli* and *Tinctura Humuli.*) A pillow of hops has proved useful in allaying restlessness and producing sleep in nervous disorders. They should be moistened with spirit previously to being placed under the head of the patient, in order to prevent rustling. Fomentations with hops, and cataplasms made by mixing them with some emollient substance, are often beneficial in local pains and tumefactions. An ointment of the powder with lard is recommended by Mr. Freake as an anodyne application to cancerous sores.

The effects of hops may be obtained most conveniently by the use of *lupulin*, though Dr. Fronmüller, having after two trials with it obtained no soporific effect, denies it a place among the narcotics with hypnotic properties. (*B. and F. Medico-chirurg. Rev.*, April, 1867, pp. 526–7.) Dr. Wm. Byrd Page, of Philadelphia, has found this substance very effectual as an antaphrodisiac, in the treatment of gonorrhœa, spermatorrhœa, and other irritated conditions of the genito-urinary apparatus; and the same result has been obtained by other practitioners. We have found it apparently effectual in irritable bladder, when other narcotics had failed. The dose of lupulin in substance is from six to twelve grains, given in the form of pills, which may be made by simply rubbing the powder in a warm mortar till it acquires the consistence of a ductile mass, and then moulding it into the proper shape. There is an officinal tincture. (See *Tinctura Lupulinæ.*) Mr. Livermore proposes an alcoholic extract of lupulin, prepared by exhausting commercial lupulin with alcohol by the process of percolation, and exposing the tincture thus formed to spontaneous evaporation. The dose will be about one-third less than that of lupulin itself. (*Am. Journ. of Pharm.*, xxv. 294.) A fluid extract and oleoresin have been introduced into the U. S. Pharmacopœia. (See *Part II.*) Lupulin may be incorporated with poultices, or formed into an ointment with lard, and used externally for the same purposes as hops.

HYDRARGYRUM. *U. S., Br.*

Mercury.

Quicksilver; Mercurius, *Lat.;* Mercure, Vif argent, *Fr.;* Quecksilber, *Germ.;* Mercurio, *Ital.;* Azógue, *Span.* and *Port.*

Mercury is found pure, forming an amalgam with silver, in the form of protochloride (native calomel), but most abundantly as the bisulphuret, or native cinnabar. Mines of this metal are found at Almaden in Spain, at Idria in Carniola, in the Duchy of Deux-ponts, in Corsica, in the Philippine Islands and

China, near Huancavelica in Peru, near Azogue in New Granada, at Durasco in Mexico, and at New Almaden, New Idria, and other localities in Santa Clara county, California, about sixty-six miles from San Francisco. The most ancient mine is that of Almaden in Spain, which was worked before the Christian era. This mine, and the mines in California, are the most productive at the present day; the Spanish mine yielding about three millions of pounds, and the California more than this amount annually. The ore in all the mines mentioned is cinnabar. The cinnabar from old Almaden is of a dull-red colour in mass, of a dull brick-red colour when in fine powder, and of the sp. gr. 3·6. That from New Almaden is of a bright-red colour, slightly inclining to purple, not so hard as the Spanish ore, of a brilliant vermilion colour in powder, and having the sp. gr 4·4. The California cinnabar is richer in mercury, because purer, than the Spanish; the former yielding about 70, the latter about 38 per cent. of mercury, according to the analyses of Mr. Adam Bealey. The California mine had been long known to the Indians, but its commercial value was first made known, about 1843, by a Mexican, named Castillero, who became its first owner. At present it is in the hands of Americans. (See *Pharm. Journ.*, Feb. 1855; also a paper by Dr. Ruschenberger, U. S. N., in the *Am. Journ. of Pharm.*, March, 1856.) Dr. Ruschenberger has detected selenium in California cinnabar. A quicksilver ore has recently been found in Macon county, Tennessee, where it is said to exist in vast quantities. According to Mr. E. S. Wayne, it is a talcose rock, and contains mercury in the metallic state, yielding 7·5 per cent. of the metal. (*Am. Journ. of Pharm.*, Jan. 1868, p. 76.)

Extraction, &c. Mercury is obtained almost exclusively from the bisulphuret, or native cinnabar. It is extracted by two principal processes. According to one process, the mineral is picked, pounded, and mixed with lime. The mixture is then introduced into cast-iron retorts, which are placed in rows, one above the other, in an oblong furnace, and connected with earthenware receivers, one-third full of water. Heat being applied, the lime combines with the sulphur, so as to form sulphuret of calcium and sulphate of lime; while the mercury distils over, and is condensed in the receivers. The other process is practised at Almaden in Spain. Here a square furnace is employed, the floor of which is pierced with many holes, for the passage of the flame from the fireplace beneath. In the upper and lateral part of the furnace, holes are made, communicating with several rows of *aludels*, formed of adapters passing into one another, which terminate in a small chamber that serves both as condenser and receiver. The mineral, having been picked by hand and pulverized, is kneaded with clay, and formed into small masses, which are placed on the floor of the furnace. Heat being applied, the sulphur undergoes combustion; while the mercury, being volatilized, passes through the aludels to be condensed in the chamber. The process pursued at New Almaden is described by Dr. Ruschenberger. (See *Am. Journ. of Pharm.*, March, 1856.)

Mercury, as found in commerce, is contained in cylindrical wrought-iron bottles, called flasks, each containing 75 pounds. Since the regular working of the California mine of New Almaden, the importation of the metal from Spain and Austria has gradually diminished, and at present the domestic production is sufficient not only to supply the home consumption, but to give an excess for exportation. The value of American mercury exported was 94,335 dollars for the year ending June 30th, 1854, and 806,119 dollars, or more than eight-fold, for the next fiscal year. (*Treasury Report on the Finances*, Washington, 1856.) The different mines of California were, in the year 1862, said to be yielding mercury at the rate of four millions of pounds per annum. (*Am. Journ. of Pharm.*, Sept. 1862, p. 410.) The exports are made principally to China, Mexico, Chili, and Peru. The chief uses of the metal are in mining silver and gold, in preparing vermilion, in making thermometers and barometers, in silvering looking-glasses, and in forming various pharmaceutical compounds.

Properties. Mercury is a very brilliant liquid, of a silver-white colour, and without taste or smell. When perfectly pure it undergoes no alteration by the

action of air or water, but in its ordinary state suffers a slight tarnish. When heated to near the boiling point, it gradually combines with oxygen, and is converted into deutoxide; but at the temperature of ebullition it parts with the oxygen which it had absorbed, and is reduced again to the metallic state. Its sp. gr. is 13·5, and its equivalent 200.* It boils at 662°, and congeals at 39° below zero, forming a malleable solid resembling lead. It is a good conductor of caloric, and its specific heat is small. It is not attacked by muriatic acid, nor by cold sulphuric acid; but boiling sulphuric acid or cold nitric acid dissolves it, generating a bisulphate or binitrate of the deutoxide; with the extrication, in the former case, of sulphurous acid; in the latter, of nitric oxide becoming hyponitric acid fumes. Its combinations are numerous, and several of them constitute important medicines. It forms two oxides, two regular sulphurets, two chlorides, three iodides, and one cyanide, all of which, excepting the protoxide, protosulphuret, and sesquiodide, are officinal. Both the oxides are capable of uniting with acids so as to form salts, of which the binitrate, sulphate, and bisulphate of the deutoxide are officinal, or enter into officinal compounds.

Mercury, as it occurs in commerce, is in general sufficiently pure for pharmaceutical purposes. Occasionally it contains foreign metals, as lead, tin, zinc, and bismuth. Mr. Brande informs us that, in examining large quantities of this metal in the London market, he found it only in one instance intentionally adulterated. When impure, the metal has a dull appearance, leaves a trace on white paper, is deficient in due fluidity and mobility, as shown by its not forming perfect globules, is not totally dissipated by heat, and, when shaken in a glass bottle, coats its sides with a pellicle, or, if very impure, deposits a black powder. If agitated with strong sulphuric acid, the adulterating metals become oxidized and dissolved, and thus the mercury may to a limited extent be purified. Lead is detected by shaking the suspected metal with equal parts of acetic acid and water, and then testing the acid by sulphate of soda, or iodide of potassium. The former will produce a white, the latter a yellow precipitate, if lead be present. Bismuth is discovered by dropping a nitric solution of the mercury, prepared without heat, into distilled water, when subnitrate of bismuth will be precipitated. The complete solubility of the metal in nitric acid shows that tin is not present; and, if sulphuretted hydrogen does not act upon muriatic acid previously boiled upon the metal, the absence of contaminating metals is shown.

Mercury may be purified by digesting it with a small portion of weak nitric acid, or with a solution of bichloride of mercury (corrosive sublimate); whereby all the ordinary contaminating metals will be removed. M. Ulex recommends its purification by triturating, for ten minutes, a pound of the metal with an ounce of the solution of sesquichloride of iron (sp. gr. 1·48), diluted with an equal measure of water. The mercury is thus divided to a very great extent, and the contaminating metals are separated as chlorides; the sesquichloride of iron being, in the mean time, reduced to protochloride. After decanting the iron solution, and washing with water, the mercury is dried by a gentle heat, and subjected to trituration, when the greater portion of it runs together. Mercury, however, is usually purified by distillation.

The British Pharmacopœia of 1864 gave the following process for the purification of mercury, using for this purpose an impure form of the metal, under the name of *Commercial Mercury* or *Quicksilver*.

"Take of Mercury of Commerce *three pounds* [*avoirdupois*]; Hydrochloric Acid *three fluid drachms;* Distilled Water a sufficiency. Place the Commercial Mercury in a glass retort or iron bottle, and applying heat cause two pounds and

* Some chemists adopt 100 as the equivalent of mercury, or half the number given in the text. There are many arguments in favour of the smaller number; but, as the pharmaceutical processes involving this metal are generally explained by the use of the larger number, we shall adhere to it for the present. The use of the smaller number makes a perplexing change in the nomenclature of the mercurial compounds. Thus, the black oxide becomes the dioxide, and the red oxide the protoxide, instead of the deutoxide. Again, calomel becomes the dichloride, and corrosive sublimate the protochloride, instead of the bichloride. (*Note to the eleventh edition.*)

a half of the metal to distil over into a flask employed as a receiver. Boil on this for five minutes the Hydrochloric Acid diluted with nine fluid drachms of Distilled Water, and having, by repeated affusions of Distilled Water and decantations, removed every trace of acid, let the mercury be transferred to a porcelain capsule, and dried first by filtering paper, and finally on a water-bath." *Br.*

Mercury, being much more volatile than the contaminating metals, rises first in distillation, while they are left behind. But it is necessary to avoid pushing the distillation too far; for in that event, some of the foreign metals are apt to be carried over. The British Council, on account of this danger, directed only five-sixths of the mercury to be distilled. The distilled product is boiled for a few minutes with dilute muriatic acid, which, while it does not attack the mercury, dissolves any contaminating metals which may have passed over. The distillation is directed to be performed from a glass retort or iron bottle; but it is more conveniently conducted from the latter, over a common fire, into water contained in a receiver. In small operations a wash-hand basin will answer for a receiver. Millon has ascertained the curious fact, that the presence of so small a quantity as one ten-thousandth of lead or zinc in mercury raises its boiling point. M. Violette has made known a new method of distilling mercury, or amalgamated silver, which presents many advantages. It consists in subjecting the metal, in iron vessels, to a current of high pressure steam, which serves the double purpose of imparting the necessary heat, and carrying over the mercurial vapour by a mechanical agency. (*Philos. Mag.*, Dec. 1850; from *Comptes Rendus.*) As it is difficult and troublesome to purify mercury by distillation, it is better to purchase pure samples of the metal, which may always be found in the market.

Medical Properties. Mercury in its uncombined state is inert; but, in combination, acts as a peculiar and universal stimulant. When exhibited in minute division, as it exists in several preparations, it produces its peculiar effects; but this does not prove that the uncombined metal is active, but only that the condition of minute division is favourable to its solution in the stomach. Its combinations exhibit certain general medical properties and effects which belong to the whole as a class; while each individual preparation is characterized by some peculiarity in its operation. In this place we shall consider the physiological action of mercury, and the principles by which its administration should be regulated; while its effects, as modified in its different combinations, will be noticed under the head of each preparation.

Of the modus operandi of mercury we know nothing, except that it probably acts through the medium of the circulation, and that it possesses a peculiar alterative power over the vital functions, which enables it in many cases to subvert diseased actions. This alterative power is sometimes exerted, without being attended with any other vital phenomenon than the removal of disease; while at other times it is attended with certain obvious effects, indicative of the agency of a potent stimulus. In the latter case, its operation is marked by a quickened circulation, by a frequent jerking pulse, by an increased activity of all the secretory functions, particularly those of the salivary glands and the liver, by an exaltation of nervous sensibility, and, in short, by a general excitation of the organic actions of the system.

When mercury acts slowly as an alterative, there is not the least apparent disturbance of the circulation. When it operates decidedly and obviously, it is very prone to let the brunt of its action fall upon the salivary glands, causing, in many instances, an immoderate flow of saliva, and constituting the condition denominated ptyalism or salivation. Under these circumstances the effects of depletion and revulsion are added to the alterative action of the metal. In the saliva discharged, as a consequence of its action, mercury has been detected by chemical tests. Occasionally its depletory action is exhibited in an increased secretion of urine, or an immoderate flow of the bile; and one or both of these effects are apt to be experienced where ptyalism cannot be induced. Mercury has been found in the urine of those under the influence of corrosive sublimate,

by M. Audouard. It has, indeed, been detected in most of the solids and fluids of the body, including the blood. When in the blood it cannot be detected by the ordinary tests, on account of its intimate union with the organic matter of that liquid. To discover it the blood must be subjected to destructive distillation. The liver is the organ which retains mercury the longest. It has been detected in that viscus, though absent in the lungs, heart, bile, and spinal marrow, in the body of a person who had long worked in mercury, but had desisted from the occupation for a year before death, on account of the occurrence of mercurial cachexy.

Mercury has been used in almost every disease, but too often empirically, and without the guidance of any recognised therapeutic principle. Nevertheless, its efficacy in certain classes of diseases is universally acknowledged. In functional derangement of the digestive organs, mercurials in minute doses often exert a salutary operation, subverting the morbid action, and that too by their slow, alterative effect, without affecting the mouth. In these cases no decided disturbance of the vital functions takes place; but the alvine discharges, if clay-coloured, are generally restored to their natural hue, a certain proof that the remedy is stimulating the liver, and promoting the secretion of the bile. Indeed, there is no fact better established in medicine than that of the influence of the mercurial preparations over the hepatic system; and, whether the liver be torpid and obstructed as in jaundice, or pouring out a redundancy of morbid bile as in melæna, its judicious use seems equally efficacious in unloading the viscus, or restoring its secretion to a healthy state. In the acute and chronic hepatitis of India it is considered as almost a specific; but here its use must be carried to the extent of exciting ptyalism. In chronic inflammation of the mucous and serous membranes, the alterative effects of mercury are sometimes attended with much benefit. In many of these cases effusion has taken place; and, under these circumstances, the mercury often proves useful, as well by promoting absorption as by removing the chronic inflammation on which the effusion depends. Hence, it is often given with advantage in chronic forms of meningitis, bronchitis, pleuritis, pneumonia, dysentery, rheumatism, &c., and in hydrocephalus, hydrothorax, ascites, and general dropsy.

Mercury may also be advantageously resorted to in certain states of febrile disease. In some forms of remittent and typhoid fever, a particular stage is marked by a parched tongue, torpor of the bowels, scanty urine, and dryness of the surface. Here depletion by the lancet or leeches is generally inadmissible, and one of the measures most to be relied on is the very cautious employment of mercury. It acts in such cases by increasing the secretions and stimulating the exhalant capillaries, and, perhaps, by producing a new impression incompatible with the disease.

In syphilitic affections, mercury, until of late years, was held to be indispensable. Of its mode of action in these affections we know nothing, except that it operates by substituting its own peculiar impression for that of the disease. Without entering into the question of the necessity of mercury in venereal complaints, we are free to admit that the discussion which has grown out of it has shown that this remedy has frequently been unnecessarily resorted to in affections resembling syphilis, though of a different character; and that the disease in question ought to be treated less empirically, and more in accordance with the general principles of combating morbid action. Mercury exerts a peculiar control over the deleterious effects of lead; and hence, in colica pictonum, it is accounted by some writers to act almost as a specific.

For inducing the specific effects of mercury on the constitution, blue pill or calomel is generally resorted to. In order to produce what we have called the slow alterative effects of the metal, from half a grain to a grain of blue pill may be given in the twenty-four hours, or from a sixth to a fourth of a grain of calomel; or, if a gentle ptyalism be our object, two or three grains of the former, or a grain of the latter, two or three times a day. Where the bowels are peculiarly irritable, it is often necessary to introduce the metal by means of friction with

mercurial ointment; and, where a speedy effect is desired, the internal and external use of the remedy may be simultaneously resorted to.

The first observable effects of mercury in inducing ptyalism are a coppery taste in the mouth, a slight soreness of the gums, and an unpleasant sensation in the sockets of the teeth, when the jaws are firmly closed. Shortly afterwards the gums begin to swell, a line of whitish matter is seen along their edges, and the breath is infected with a peculiar and very disagreeable smell, called the mercurial fetor. The saliva at the same time begins to flow; and, if the affection proceeds, the gums, tongue, throat, and face are much swollen; ulcerations attack the lining membrane of the mouth and fauces; the jaws become excessively painful; the tongue is coated with a thick whitish fur; and the saliva flows in streams from the mouth. It occasionally happens that the affection of the mouth proceeds to a dangerous extent, inducing extensive ulceration, gangrene, and even hemorrhage. The best remedies are astringent and detergent gargles, used weak at first, as the parts are extremely tender. In cases attended with swelling and protrusion of the tongue, the wash is best applied by injection, by means of a large syringe. We have found lead-water among the best applications in these cases; and dilute solutions of chlorinated soda or of chlorinated lime, while they correct the fetor, will be found to exert a curative influence on the ulcerated surfaces. A wash of nitrate of silver, made by dissolving eight grains in a fluidounce of water, has also been used with benefit.

While the system is under the action of mercury, the blood is more watery than in health less charged with albumen, fibrin, and red globules, and loaded with a fetid fatty matter. (*Dr. S. Wright*, quoted by *Christison*.) When drawn from a vein, it exhibits the same appearance as in inflammation.

In the foregoing observations, we have described the ordinary effects of mercury; but occasionally, in peculiar constitutions, its operation is quite different, being productive of a dangerous disturbance of the vital functions. The late Mr. Pearson gave a detailed account of this occasional peculiarity in the operation of mercury, in his work on the venereal disease. The symptoms which characterize it are a small and frequent pulse, anxiety about the præcordia, pale and contracted countenance, great nervous agitation, and alarming debility. Their appearance is the signal for discontinuing the mercury; as a further perseverance with it might be attended with fatal consequences. Mercury also produces a peculiar eruption of the skin, which is described by writers under the various names of *hydrargyria*, *eczema mercuriale*, and *lepra mercurialis*.

Those who work in mercury, and are, therefore, exposed to its vapour, such as water-gilders, looking-glass silverers, and quicksilver miners, are injured seriously in their health, and not unfrequently affected with shaking palsy, attended with vertigo and other cerebral disorders. The miners are often salivated.

Many plants, exposed to the influence of the vapour spontaneously rising from mercury in confined air, perish in a few days; while, if sulphur be placed by the side of the metal, no effect of the kind is experienced. (Boussingault, *Journ. de Pharm. et de Chim.*, Sept. 1867, p. 176.) A probable inference from this fact is, that workmen, necessarily exposed to the vapour of mercury, might be protected by the presence of sulphur in sufficient quantity.

Mercury is sometimes given in the metallic state, in the quantity of a pound or two, in obstruction of the bowels, to act by its weight: but the practice is of doubtful advantage.

Mercury is detected with great delicacy by Smithson's process, which consists in the use of a plate of tin, lined with one of gold, in the form of a spiral. When immersed in a mercurial solution, this galvanic combination causes the precipitation of the mercury on the gold, which consequently contracts a white stain. In order to be sure that the stain is caused by mercury, the metal must be volatilized in a small tube, so as to obtain a characteristic globule. MM. Danger and Flandin have improved on Smithson's process. (See *Chem. Gaz.*, no. 61, p. 191.) A minute portion of any of the preparations of mercury, either in the solid state or in concentrated solution, being placed on a bright plate of

copper, and a drop of a strong solution of iodide of potassium added, a silvery characteristic stain will immediately appear on the copper.

Mercury is officinal:—

HYDRASTIS. *U. S. Secondary.*

Hydrastis.

The root of Hydrastis Canadensis. *U. S.*

Hydrastis. *Sex. Syst.* Polyandria Polygynia. — *Nat. Ord.* Ranunculaceæ.

Gen. Ch. *Calyx* of three petalloid sepals, falling when the flower opens. *Ovaries* in a roundish-ovoid head; *stigmas* subsessile, dilated, flat, rounded at the apex. *Carpels* fleshy, one or two-seeded, cohering in a compound berry.

This genus was at first included by Linnæus in Hydrophyllum, but was afterwards separated, and received the name by which it is now generally recognised. The officinal species is the only known one of the genus.

Hydrastis Canadensis. Gray, *Manual of Bot.* p. 14; figured in Griffith's *Med. Bot.* p. 82. — *Yellow-root. Orange-root. Yellow Puccoon.* This is a small, herbaceous, perennial plant, with a thick, fleshy, yellow rhizoma, from which numerous long radical fibres proceed, and an erect, simple, pubescent stem, from six inches to a foot in height. There are usually but two leaves, which are unequal, one sessile at the top of the stem, the other attached to it a short distance below by a thick, roundish footstalk, causing the stem to appear as if bifurcate near the summit. The leaves are pubescent, roundish-cordate, with from three to seven, but generally five lobes, which are pointed and unequally serrate. A solitary flower stands upon a peduncle rising from the basis of the upper leaf. It is whitish, rose-coloured, or purplish, without corolla, but with a coloured calyx, the sepals of which closely resemble petals, and are very caducous, falling very soon after the flower has expanded. The fruit is a globose, compound, red or purple berry, half an inch or more in diameter, composed of many minute granules, each containing one, or more rarely two seeds. The plant grows in moist, rich woodlands, in most parts of the United States, but abundantly in the North and West. The fruit bears a close resemblance to the raspberry, but is not edible. The root is the part employed. Though long in use in domestic and empirical practice, and more or less among regular practitioners, it was not recognised as officinal before the publication of the present edition of the U. S. Pharmacopœia, in which it holds a place in the Secondary Catalogue. The Indians employed it for staining and dyeing yellow, and it is said to impart a rich and permanent yellow, and with indigo a fine green to wool, silk, and cotton.

Properties. The fresh root is juicy and loses much of its weight in drying. The dried caudex or rhizoma is contorted, irregular, very rough and wrinkled, hard and brittle, from an inch to two inches or more in length, usually two or three lines in thickness, and either beset with numerous slender rootlets, or showing marks upon the surface where they have been broken off. Many of the detached rootlets are mixed with the rhizomas in mass. The colour of the rhizoma, though yellow in the recent root, becomes of a dark yellowish-brown by age; that of the rootlets and the interior of the root is yellow, and of the powder still more so. The odour is strong, sweetish, and somewhat narcotic, the taste bitter and peculiar. The root imparts its virtues and colouring matters to water and alcohol. Examined by Mr. Alfred A. B. Durand, of Philadelphia, it was found to contain albumen, starch, fatty matter, resin, yellow colouring matter, sugar, lignin, and various salts. He also discovered a peculiar nitrogenous, crystallizable substance, for which he proposed the provisional name of *hydrastin*, until it should be determined whether it was, as he suspected, an organic alkali. (*Am. Journ. of Pharm.*, April, 1851, p. 112.) Since that time it has been ascertained that the claims of this principle to be considered an alkaloid were just, and it has definitely taken the name of *hydrastia*, of which *hydrastin* and *hydrastina* are merely synonymes. It has also been determined that the root contains another alkaloid, to which it owes its yellow colour, and which is probably identical with the yellow colouring matter of Mr. Durand. A muriate of this latter alkaloid, obtained by the precipitation essentially of an infusion of the root by mu-

riatic acid, has been for some time known and used by the "Eclectics" under the name of hydrastin, and the reader must be cautious not to confound this substance with the alkaloid to which the name properly belongs. Mr. F. Mahla first ascertained that this new alkaloid of hydrastis is in fact *berberina* (*Am. Journ. of Sci. and Arts*, Jan. 1862, p. 43), which was long since found in the root of Berberis vulgaris, and has since been detected in columbo, and other medicinal roots. An account of its mode of preparation and properties is contained in the article on *Berberis*. (See *page* 176.) It exists in large proportion in hydrastis, constituting, according to Perrins, nearly 4 per cent. There can be no doubt that this medicine owes much of its virtues to berberina.

Hydrastia, which is its characteristic alkaloid, may be obtained by exhausting the powdered root as far as possible with water by percolation, adding muriatic acid to the infusion so as to precipitate the berberina in the form of muriate, and treating the mother-liquor with solution of ammonia in slight excess. The hydrastia is precipitated, in an impure state, and may be purified by repeated solution in boiling alcohol, which deposits it in crystals on cooling. A little animal charcoal may be used towards the close of the process, in order completely to deprive the crystals of colour. To Mr. Mahla, of Chicago, and Mr. Perrins, of London, is due the credit of having fully investigated the properties of this alkaloid.* Hydrastia crystallizes in brilliant, four-sided prisms, which are white or colourless when pure, inodorous, and almost tasteless in consequence of their insolubility in the saliva, but become bitter and somewhat acrid in saline combination. It melts at 275° F., is decomposed at a higher temperature, and is inflammable. It is nearly insoluble in water, but is readily dissolved by alcohol, ether, chloroform, and benzole. It has an alkaline reaction, and with the acids forms salts, most of which are readily soluble in water, and, according to Mr. Merrill, of Cincinnati, either uncrystallizable, or crystallizable with difficulty. The alkalies and tannic acid precipitate it from its saline solutions. With sulphuric acid and bichromate of potassa or red oxide of lead, it assumes a red colour; but differs from strychnia in exhibiting no tint of blue or violet. Its constituents are carbon, hydrogen, nitrogen, and oxygen, and its formula, as given by Mr. Mahla, is $C_{44}H_{24}NO_{12}$. Mr. Perrins obtained 1·5 per cent. of it from the root; and, having given five grains of it to a rabbit, without any other effect than a slight uneasiness which soon ceased, concluded justly that it was not poisonous.

It is highly probable, from the odour of hydrastis, that, besides the two alkaloids here mentioned, it contains also an active volatile principle; but this has not yet been isolated.

Medical Properties and Uses. Very diversified powers have been claimed for hydrastis. Thus, while all admit its tonic properties, it is considered by different practitioners as aperient, alterative in its influence on the mucous membranes, cholagogue, deobstruent in reference to the glands generally, diuretic, antiseptic, &c. It has been employed in dyspepsia and other affections requiring tonic treatment, in jaundice and other functional disorders of the liver, as a laxative in constipation and piles, and as an alterative in various diseases of the mucous membranes, as catarrh, chronic enteritis, cystirrhœa, leucorrhœa, gonorrhœa, &c., being used in the latter complaints both internally and locally. By some it is used as one of the best substitutes for quinia in intermittents. In the form of infusion, it has been used in the Western States as a topical application in ophthalmia; and the Indians are said to employ it in the same manner in old ulcers of the legs. The notion of its efficacy in cancer, originating in a report which reached the late Professor Barton, that it was used in the cure of this complaint by the Cherokees, is probably altogether groundless. Dr. U. E. Ewing, of Lexington, Ky., and Dr. D. M. McCann, of Martinsburg, Ohio, have recommended an infusion or decoction of the root as an injection in gonorrhœa. Dr. McCann made the decoction in the proportion of a drachm of the dried root to a pint of water, and injected a syringeful three times a day. Dr. Ewing used

* For a paper by Mr. Mahla, see *American Journal of Sci. and Arts*, July, 1863, p. 57, and for another by Mr. J. Dyson Perrins, of London, the *Pharm. Journ.*, May, 1862, p. 546.

the infusion with the addition of *sulphate of copper*. (*Med. Examiner*, N. S., vii. 733.) Dr. P. C. Gooch has subsequently used it in five cases, and obtained no good effect whatever. (*Am. Journ. of Med. Sci.*, N. S., xxiii. 286.) But a more precise investigation into its physiological and therapeutic properties is necessary, before we can venture to decide upon its place among medicines.

It has been given in the form of infusion, decoction, tincture, and extract; but no preparation is yet officinal. Till regular formulas are adopted, the root may be treated like columbo or gentian. The impure muriate of berberina, obtained as above mentioned from hydrastis, is used by the "Eclectics," under the name of hydrastin, in the dose of from three to five grains. Hydrastis might probably be advantageously prepared in the form of a fluid extract; as little as possible of its odorous volatile principle being allowed to escape. W.

HYOSCYAMUS. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solanaceæ.

Gen. Ch. Corolla funnel-form, obtuse. *Stamens* inclined. *Capsules* covered with a lid, two-celled. *Willd.*

Hyoscyamus niger. Willd. *Sp. Plant.* i. 1010; Woodv. *Med. Bot.* p. 204, t. 76; Carson, *Illust. of Med. Bot.* ii. 19, pl. 66. Henbane is usually a biennial plant, with a long, tapering, whitish, fleshy, somewhat branching root, not unlike that of parsley, for which it has been eaten by mistake, with poisonous effects. The stem, which rises in the second year, is erect, round, branching, from one to four feet high, and thickly furnished with leaves. These are large, oblong-ovate, deeply sinuated with pointed segments, undulated, soft to the touch, and at their base embrace the stem. The upper leaves are generally entire. Both the stem and leaves are hairy, viscid, and of a sea-green colour. The flowers form long, one-sided, leafy spikes, which terminate the branches, and hang downwards. They are composed of a calyx with five pointed divisions, a funnel-shaped corolla, with five unequal, obtuse segments at the border, five stamens inserted into the tube of the corolla, and a pistil with a blunt, round stigma. Their colour is an obscure yellow, beautifully variegated with purple veins. The fruit is a globular two-celled capsule, covered with a lid, invested with the persistent calyx, and containing numerous small seeds, which are discharged by the horizontal separation of the lid. The whole plant has a rank offensive smell.

H. niger is susceptible of considerable diversity of character, causing varieties which have by some been considered as distinct species. Thus, the plant is sometimes annual, the stem simple, smaller, and less downy than in the biennial plant, the leaves more deeply incised and less hairy and viscid, and the flowers often yellow without the purple streaks. It has been ascertained that much difference of medical properties is connected with these diversities of character; and the British Pharmacopœia directs the biennial variety as the most efficient.

The plant is found in the northern and eastern sections of the United States, occupying waste grounds in the older settlements, particularly graveyards, old

gardens, and the foundations of ruined houses. It grows in great abundance about Detroit, in Michigan. It is not, however, a native of this country, having been introduced from Europe. In Great Britain, and on the continent of Europe, it grows abundantly along the roads, around villages, amidst rubbish, and in uncultivated places. Both varieties are cultivated in England. The annual plant flowers in July or August, the biennial in May or June.*

H. albus, so named from the whiteness of its flowers, is used in France indiscriminately with the former species, with which it appears to be identical in medicinal properties.

All parts of *Hyoscyamus niger* are active. The leaves are usually employed, but both these and the seeds are recognised in the U. S. Pharmacopœia. Much of the efficacy of henbane depends upon the time at which it is gathered. The leaves should be collected soon after the plant has flowered. In the biennial plant, those of the second year are preferred to those of the first. The latter, according to Dr. Houlton, are less clammy and fetid, yield less extractive, and are medicinally much less efficient. It is said that the plant is sometimes destroyed by severe winters in England, and that no leaves of the second year's growth are obtainable. This is, perhaps, one of the causes of the great uncertainty of the medicine as found in the shops. The root also is said to be much more poisonous in the second year than in the first.†

Properties. The recent leaves have, when bruised, a strong, disagreeable, narcotic odour, somewhat like that of tobacco. Their taste is mucilaginous and very slightly acrid. When dried, they have little smell or taste. Thrown upon the fire, they burn with a crackling noise as if they contained a nitrate, and at the same time emit a strong odour. Their virtues are completely extracted by diluted alcohol. The watery infusion is of a pale-yellow colour, insipid, with the narcotic odour of the plant. The leaves were analyzed by Lindbergsen, who obtained from them a narcotic principle. They contain a large proportion of nitrate of potassa; Mr. F. Mahla having obtained, as nearly as he could estimate from his experiments, 2 per cent. of that salt. (*Am. Journ. of Pharm.*, Sept. 1859, p. 402.) The seeds are very small, roundish, compressed, somewhat kidney-shaped, a little wrinkled, of a gray or yellowish-gray colour, of the odour of the plant, and an oleaginous, bitterish taste. Analyzed by Brandes, they yielded 24·2 per cent. of fixed oil, 1·4 of a solid fatty substance, traces of sugar, 1·2 of gum, 2·4 of bassorin, 1·5 of starch, 3·4 of a substance soluble in water, insoluble in alcohol, and precipitated by infusion of galls (phyteumacolla, *Brandes*), 4·5 of albumen, 26·0 of vegetable fibre, 24·1 of water, and 9·7 of salts, including the malate of an alkaloid called *hyoscyamin* or *hyoscyamia*. But the process employed by Brandes for separating this principle has not succeeded in other hands; and it is doubtful whether the substance obtained by him was really what he supposed it to be. Geiger and Hesse were the first

* For an account of the cultivation of the biennial variety of H. niger at Hitchin, Herts, England, see *Pharm. Journ.*, Feb. 1860, p. 414.

† The following important facts in relation to the cultivation of henbane and the relative strength of the different varieties, and of the same under different circumstances, are taken from a communication by M. Rufus Usher, a cultivator of medicinal plants, to the *Journal of the Society of Arts*, and republished in the *Lond. Pharm. Journ.* (Aug. 1867). The several products of the henbane plants are placed by Mr. Usher in the following order, as to efficiency: 1. the leaves of the biennial plant of the second year's growth; 2. the biennial plant of the first year; 3. the British annual henbane; 4. the German annual henbane. The last two, though most extensively used, are really nearly valueless, and should always be rejected. The British annual so nearly resembles the biennial of the second year, having flowers, that the two may be easily mistaken for one another; but a sufficient distinction is that the annual plant "possesses no flavour or aroma." Besides, the leaves are much shorter; and occasionally there is a pure primrose blossom, which never happens with the biennial, which is beautifully streaked. The biennial plant is so liable to the attacks of worms, that at one time little of the second year's growth was collected, and the market was consequently supplied with a very inferior article. But from the great attention recently paid to its cultivation, it may now be furnished at reasonable prices; and we may hope to be supplied with efficient preparations of this valuable narcotic. (*Note to the thirteenth edition.*)

to demonstrate the existence of an organic alkali in hyoscyamus. Its extraction from the plant is somewhat difficult, in consequence of its tendency to undergo change by the contact of alkaline solutions, which render it very soluble in water. The following is the process of these chemists. The seeds are macerated in alcohol; the tincture obtained is evaporated by a very gentle heat, decolorized by repeated additions of lime and sulphuric acid, with filtration after each addition, and then still further concentrated by evaporation; an excess of powdered carbonate of soda is added, and the precipitate produced is separated, as speedily as possible, from the alkaline carbonate by expressing and treating it with absolute alcohol, while the mother-waters are at the same time treated with ether; the alcoholic and ethereal liquors are united, again treated with lime, filtered, decolorized with animal charcoal, and evaporated by a very gentle heat. If the hyoscyamia now deposited should still be coloured, it will be necessary to combine it anew with an acid, and proceed as before, in order to obtain it quite pure. The product is very small.*

From experiments made by Mr. Hirtz upon the relative medicinal power of extracts from the seeds and leaves, he inferred that the former had ten times the strength of the latter.

Hyoscyamia crystallizes in colourless, transparent, silky needles, is inodorous, of an acrid disagreeable taste, slightly soluble in water, very soluble in alcohol and ether, and volatilizable with little change if carefully distilled. It is quickly altered by contact with water and an alkali, and when heated with potassa or soda is completely decomposed, with the disengagement of ammonia. It neutralizes the acids, forming crystallizable salts, and is precipitated by infusion of galls. The alkaloid and its salts are very poisonous; and the smallest quantity, introduced into the eye, produces dilatation of the pupil, which continues long. From the experiments, however, of Professors Erdmann and Kolbe, it appears to be inferior in this respect to atropia. In relation to its chemical properties, it is stated by these experimenters, contrary to what has been previously asserted, that hyoscyamia in concentrated solution gives with a drop of muriatic acid and bichloride of platinum a yellow crystalline precipitate, whilst a weak solution gives no precipitate whatever with the bichloride. (*Neues Repertorium*, A. D. 1867, p. 502.) M. Reynard adds to what is known of the chemical properties of hyoscyamia the following facts. The alkaloid is precipitated by the concentrated alkalies, but not when these are diluted. Phosphomolybdate of soda precipitates it yellowish-white, passing to green when it is heated with ammonia. With iodobismuthate of potassa it affords an orange, with iodohydrargyrate of potassa a white, and with tannin a yellowish precipitate, while chloride of gold produces a magma consisting of yellowish flakes and a brown resinous mass. (*Journ. de Pharm. et de Chim.*, Mars, 1868, p. 238.)

* Mr. Wm. A. Tilden, after unsatisfactory trials with Geiger's and Sonnenschein's processes for obtaining hyoscyamia, for the latter of which the reader is referred to Mr. Tilden's paper, succeeded in procuring it by the following method. Half a pound of freshly prepared extract of the leaves was dissolved in three pints of water mixed with a very little milk of lime, and filtered. To the clear liquid carbonate of potassa was added till it became strongly alkaline, and the whole shaken with a pint of chloroform. After standing all night, the chloroform had subsided with the appearance of a greenish oil. This having been separated by a funnel, filtered into a bottle, and shaken with water acidulated with sulphuric acid, the chloroform was recovered. The aqueous liquid was made alkaline with carbonate of potassa, and shaken with ether. The ether, which contained all the hyoscyamia, was shaken with acidulated water, and distilled over a water-bath. The acid solution remaining, neutralized with bicarbonate of soda, gave a dirty-white precipitate soluble in acetic acid with tannin, a yellowish flocculent precipitate with chloride of gold, a brown one with iodine dissolved in hydriodic acid, and none with bichloride of platinum or corrosive sublimate. The alkaloid is very soluble in alcohol, ether, chloroform, and even water; and in aqueous solution has a strongly acrid and bitter taste. It is generally obtained as a colourless gummy mass; but, when its solution has been suffered to evaporate over sulphuric acid, it has crystallized in groups of radiating needles. It has a slight odour quite different from that of the plant, and is decidedly alkaline to test paper. It is rapidly destroyed by the caustic alkalies, especially with heat; an alkaline vapour, probably ammonia, being evolved. (*Pharm. Journ. and Trans.*, 2d ser., viii. 127, A. D 1867.)—*Note to the thirteenth edition.*

Henbane leaves yield, by destructive distillation, a very poisonous empyreumatic oil.

Medical Properties and Uses. Hyoscyamus ranks among the narcotics. In moderate quantities it usually accelerates the circulation, increases the general warmth, occasions a sense of heat in the throat, and after a short period induces sleep. This action is sometimes attended with vertigo, pain in the head, and dilated pupils; and the medicine occasionally acts as a diaphoretic or diuretic, and even produces a pustular eruption. It does not constipate like opium, but, on the contrary, often proves laxative. In overdoses it powerfully irritates the brain and alimentary canal, causing dilatation of the pupil, disordered vision, loss of speech, difficult deglutition, delirious intoxication or stupor, great restlessness or jactitation, sometimes tonic spasms, convulsions, paralysis, pain in the bowels, diarrhœa, excitement of the circulation, followed by great feebleness of the pulse, coldness of the surface, petechiæ, and other alarming symptoms, which sometimes end in death. Dissection exhibits marks of inflammation of the stomach and bowels. The poisonous effects are to be counteracted in the same manner as those of opium. Dr. Garrod has suggested animal charcoal as an antidote, as it has the property of absorbing the active principle, and thus rendering it inert. All parts of *H. niger* are deleterious when largely taken; but the seeds are said to be most powerful. Upon inferior animals its effects are not always the same. Though fatal to birds and dogs, the leaves are eaten with entire impunity by horses, cows, sheep, goats, and swine. It is not impossible that injury has in some cases resulted from the use of milk, derived from cows or goats which had been feeding on henbane. According to Dr. Garrod, the remedial properties of hyoscyamus are completely neutralized by solution of potassa or soda; so that they cannot properly be combined in prescriptions; but as the carbonates of the alkalies have no such effect, these should be substituted. From these facts it might be inferred that the caustic alkalies would be the best antidote to the poisonous effects of hyoscyamus; but the quantity required would be so great as to endanger the integrity of the gastric mucous membrane, and thus probably to cause more danger than the poison itself. (*Med. Times and Gaz.*, Dec. 1857, p. 589.)

The remedial operation of hyoscyamus is anodyne and soporific. The medicine was known to the ancients, and was employed by some of the earlier modern practitioners; but had fallen into disuse, and was almost forgotten, when Baron Störck again introduced it into notice. By this physician and some of his successors it was prescribed in numerous diseases, and, if we may credit their testimony, with the happiest effects; but subsequent experience of its operation has been such as very much to narrow the extent of its application. It is at present used almost exclusively to relieve pain, procure sleep, or quiet irregular nervous action; and is not supposed to exercise any specific curative influence over particular diseases. Even for the purposes which it is calculated to answer it is infinitely inferior to opium or its preparations; and is generally resorted to only in cases in which the latter remedy is from peculiar circumstances deemed inadmissible. Hyoscyamus, however, has this great advantage over opium in certain cases, that it has no tendency to constipate. The diseases to which it is applicable it would be useless to enumerate, as there are few in which circumstances might not be such as to call for its employment. Neuralgic and spasmodic affections, rheumatism, gout, hysteria, and various pectoral diseases, as catarrh, pertussis, asthma, phthisis, &c., are among those in which it is most frequently prescribed. It is also much used in connection with griping cathartics, the disagreeable effects of which it is thought to counteract. The officinal *pills of colocynth and henbane* are formed upon this principle. In Europe, where the fresh leaves are readily obtained, it is often applied externally in the shape of lotion, cataplasm, or fomentation, to allay pain and irritation, in scrofulous or cancerous ulcers, scirrhous, hemorrhoidal, or other painful tumours, gouty and rheumatic swellings, and nervous headache. The smoke of the leaves or seeds has also been used in toothache; but the practice

is deemed hazardous. Henbane is used by European oculists for dilating the pupil, previously to the operation for cataract. For this purpose an infusion of the leaves, or a solution of the extract, is dropped into the eye. The effect is usually greatest at the end of four hours from the application, and in twelve hours ceases entirely. Vision is not impaired during its continuance. Reisinger recommends a solution of hyoscyamia in the proportion of one grain to twenty-four of water, of which one drop is to be applied to the eye. Its solubility in water gives it an advantage for this purpose over atropia, the alcoholic solution of which irritates the conjunctiva. According to Schroff, there is nothing which acts so quickly and so powerfully in dilating the pupil. He uses one part of hyoscyamia, one hundred parts of water, and ten of alcohol, the latter fluid being added to prevent decomposition. (*Annuaire de Thérap.*, A. D. 1858, p. 25.)

Henbane may be given in substance, extract, or tincture. The dose of the powdered leaves is from five to ten grains, of the seeds somewhat smaller. The common extract, or inspissated juice of the fresh leaves (*Extractum Hyoscyami, U. S.*), is exceedingly variable in its operation, being sometimes active, sometimes almost inert. The usual dose is two or three grains, repeated and gradually increased till its effects are obtained. Cullen rarely procured its anodyne operation till he had carried the dose to eight, ten, or even fifteen or twenty grains. Collins pushed it to thirty-six grains; and Professor Fouquier, who experimented largely with hyoscyamus in the Hôpital de la Charité, gave two hundred and fifty grains of the extract during twenty-four hours, without any specific or curative impression. (Richard, *Elém. Hist. Nat. Méd.*) The alcoholic extract, prepared from the recently dried leaves (*Extractum Hyoscyami Alcoholicum, U. S.*), is said to be more certain. The dose of this to begin with is one or two grains, which may be increased gradually to twenty or thirty grains. An extract from the seeds would, no doubt, be much more efficacious. The dose of the tincture is one or two fluidrachms. A fluid extract is directed by the U. S. Pharmacopœia. (See *Extractum Hyoscyami Fluidum.*) A good plan, in administering any of the preparations, is to repeat the dose every hour or two till its influence is felt. Schroff has given hyoscyamia with good effects in allaying cough and procuring sleep, prescribing it in the form of powder mixed with sugar, in doses varying from the sixtieth to the twentieth of a grain. He has found the tenth of a grain too much.

Hyoscyamia has not yet been obtained in quantities sufficient for general use; but, considering the great uncertainty of henbane itself as derived from different sources, it would be a very desirable substitute. Dr. John Harley has given an account of its effects, which appears to be the result of his own observations. Given to an adult subcutaneously in doses insufficient to cause dryness of the mouth, it produces giddiness, somnolency, dilatation of the pupils, and a gradually diminishing frequency of pulse, without lessening of its force or volume. In quantities sufficient to cause dryness of the mouth, it generally occasions increased frequency of pulse with slight increase of its volume and strength. This acceleration generally begins from 10 to 20 minutes after injection, and continues for 20 or 30 minutes, very rarely for an hour. Dryness of the mouth begins about 20 minutes after injection, and lasts for an hour. In most instances there is great sleepiness, with much giddiness, so that the patient cannot walk steadily. The face is flushed and the conjunctiva injected, and the pupils dilate. At the subsidence of the symptoms, which usually begins in an hour, the pulse falls below its natural standard of frequency, sometimes even to 42 in the minute, retaining, however, its volume and power. The maximum dilatation of the pupil is at this period. The effects are precisely the same when the medicine is given by the mouth. The most prominent effects of hyoscyamus or its active principle are excessive giddiness and somnolency; while atropia, which resembles it in its effects on the mouth and pupils, produces much less of these effects. According to Dr. Harley, atropia is characterized more especially by its influence on the sympathetic nervous system, hyoscyamia on the brain. Hyoscyamia increases the soporific powers of opium; and quantities of hyoscyamia

and morphia, which in themselves are insufficient to induce sleep, will cause it when combined. Like atropia, it is eliminated by the kidneys, and was detected by Dr. Harley in the urine 22 minutes after subcutaneous injection. Therapeutically Dr. Harley has found hyoscyamia extremely useful in irritable states of the brain and the heart, and in determining and invariably increasing the soporific effect of opium. (*Med. Times and Gaz.*, April, 1868, p. 876.)

ICHTHYOCOLLA. *U. S.*

Isinglass.

The swimming bladder of Acipenser Huso, and of other species of fish. *U. S.*

Fish-glue; Ichthyocolle, colle de poisson. *Fr.;* Hausenblase, Fischleim, *Germ.;* Colla di pesce, *Ital.;* Cola de pescado, *Span.*

Isinglass is a gelatinous substance, prepared chiefly from the sounds or swimming bladders of fishes, especially those of different species of sturgeon. Though not retained in the British Pharmacopœia, it still has a place in that of the U. States, and is universally kept in the shops.

In most fishes there is a membranous bag, placed in the anterior part of the abdomen, communicating frequently, though not always, by means of a duct, with the œsophagus or stomach, and containing usually a mixture of oxygen and nitrogen gases in various proportions. From the supposition that it was intended by its expansion or contraction to enable the fish to rise or sink in the water, it has been denominated *swimming bladder*. It is of different shape in different fishes, and consists of three coats, of which the two interior are thin and delicate, the outer tough and of a silvery whiteness.

The *Acipenser Huso*, or *beluga* of the Russians, is particularly designated by the Pharmacopœia as the species of sturgeon from which isinglass is procured; but three others, the *A. Ruthenus*, or sterlet, *A. sturio*, or common sturgeon, and *A. stellatus*, or starred sturgeon, also furnish large quantities to commerce. All these fish inhabit the interior waters of Russia, especially the Wolga and other streams which empty into the Caspian Sea. Immense numbers are annually taken, and consumed as food by the Russians. The air-bags are removed from the fish, and, having been split open and washed in water in order to separate the blood, fat, and adhering extraneous membranes, are spread out, and when sufficiently stiffened are formed into cylindrical rolls, the ends of which are brought together and secured by pegs. The shape given to the roll is that of a staple, or more accurately that of a lyre, which it firmly retains when dried. Thus prepared it is known in commerce by the name of *staple isinglass*, and is distinguished into the *long* and *short staple*. Sometimes the membranes are dried in a flat state, or simply folded, and then receive the name of *leaf* or *book isinglass*. The scraps or fragments of these varieties, with various other parts of the fish, are boiled in water, which dissolves the gelatin, and upon evaporation leaves it in a solid state. This is called *cake isinglass*, from the shape which it is made to assume. It is sometimes, however, in globular masses. Of these varieties, the *long staple* is said to be the best; but the finest *book isinglass* is not surpassed by any brought to this country. It is remarkable for its beautiful iridescence by transmitted light. One hundred grains of this isinglass dissolve in ten ounces of water, forming a tremulous jelly when cold, and yield but two grains of insoluble residuum. That in *cakes* is brownish, of an unpleasant odour, and employed only in the arts. Inferior kinds, with the same commercial titles, are said to be prepared from the peritoneum and intestines of the fish. An inferior Russian product, known in English commerce by the name of *Samovey isinglass*, is procured, according to Pereira, from the *Silurus Glanis*. It comes, like the better kind, in the shape of *leaf*, *book*, and *short staple*.

Isinglass, little inferior to the Russian, is made in Iceland from the sounds of the cod and ling. It is said also to be prepared by the fishermen of Newfound-

land. We receive from Brazil the air-bladders of a large fish, prepared by drying them in their distended state. They are oblong, tapering, and pointed at one end, bifid with the remains of their pneumatic duct at the other, and of a firm consistence. The Brazilian isinglass is inferior to the Russian. Considerable quantities have been manufactured in New England, as formerly supposed, from the intestines of the cod, and of other allied fishes. This sort is in the form of thin ribbons several feet in length, and from an inch and a half to two inches in width. One hundred grains dissolve almost entirely in water, leaving but two grains of insoluble membrane, and form a tremulous jelly when cold with eight ounces of water. It is, therefore, as pure and nearly as strong a gelatin as the Russian isinglass; but it retains a fishy taste and odour, which render it unfit for culinary or medicinal purposes. Isinglass of good quality has also been made in New York from the sounds of the weak fish—*Otolithus regalis* of Cuvier (Storer, *Rep. on Fishes of Mass.*, p. 33)—and perhaps of other fishes caught in the neighbourhood. The sounds are dried whole, or merely split open, and vary much in size and texture, weighing from a drachm to an ounce. An article called "*refined or transparent isinglass*" is made by dissolving the New England isinglass in hot water, and spreading the solution to dry on oiled muslin. It is in very thin transparent plates, and is an excellent glue, but retains a strong fishy odour. A preparation called *Cooper's gelatin* has been introduced as a substitute for isinglass in making jellies. It appears to be the dried froth of a solution of pure bone glue. Most of the above facts, in relation to American isinglass, were derived from papers by D. B. Smith, in the *Journ. of the Phil. Col. of Pharm.* (iii. 17 and 92).

Mr. C. T. Carney states that the New England isinglass is prepared, not as supposed from the intestines of fish, but from the sounds of the hake (*Gadus merluccius*), by the following process. Having been taken from the fish, split open, cleansed, and dried, they are soaked in water till sufficiently soft, then passed through rollers so as to form a large, homogeneous, dough-like sheet, which is cut into strips, and then again passed through rollers till reduced to a ribbon-like form. The pieces thus prepared are thoroughly dried, and folded into bundles. (*Proceed. of Am. Pharm. Assoc.*, A. D. 1857.)

Isinglass is sometimes kept in the shops cut into fine shreds, and is thus more easily acted on by boiling water.

Properties. In its purest form it is whitish, semi-transparent, of a shining, pearly appearance, and destitute of smell and taste. The inferior kinds are yellowish and more opaque. In cold water it softens, swells up, and becomes opalescent. Boiling water entirely dissolves it, with the exception of a minute proportion of impurities, amounting, according to Mr. Hatchet, to less than 2 per cent. The solution on cooling assumes the form of a jelly, which consists of pure gelatin and water. Isinglass is in fact the purest form of *gelatin* with which we are acquainted, and may be used whenever this principle is required as a test. It is insoluble in alcohol, but is dissolved readily by most of the diluted acids, and by alkaline solutions. It has a strong affinity for tannin, with which it forms an insoluble compound. Boiled with sulphuric acid, it is converted into a peculiar saccharine matter, called *glycocoll* or *sugar of gelatin*. Its aqueous solution speedily putrefies.

An ingenious adulteration of isinglass has been practised in London, apparently by rolling a layer of gelatin between two layers of the genuine substance. This may be detected by the disagreeable odour and taste of the adulterated drug, and the effects of water upon it. Genuine isinglass, cut into shreds and treated with water, becomes opalescent and more opaque than before; while the shreds, though they soften and swell, remain unbroken, and, when examined by the microscope, are seen to be decidedly fibrous. Gelatin, on the contrary, when similarly treated, becomes more transparent than before; the shreds are disintegrated, and the structure appears amorphous under the microscope. In the adulterated article, both these characters are presented in layers more or less distinct. (*Pharm. Journ.*, ix. 505.)

A *false isinglass* has been imported into England from Para, in Brazil, consisting of the dried ovary of a large fish. It has somewhat the form of a bunch of grapes, consisting of ovoid or roundish masses, attached by a footstalk to a central axis. It is not gelatinous, and is unfit for the purposes to which isinglass is applied. (See *Am. Journ. of Pharm.*, xxv. 144.)*

Medical Properties and Uses. Isinglass has no peculiar medical properties. It may be given internally, in the form of jelly, as a highly nutritious article of diet; but it has no advantage over the jelly made from calves-feet. Three drachms impart sufficient consistency to a pint of water. It is employed for clarifying liquors, and imparting lustre to various woven fabrics. Added in small quantities to vegetable jellies, it gives them a tremulous appearance, which they want when unmixed. As a test of tannin it is used in solution, in the proportion of a drachm to ten fluidounces of distilled water. It forms the basis of the *English court-plaster*. W.

IGNATIA. *U. S.*

Ignatia. Bean of Saint Ignatius.

The seed of Strychnos Ignatia (*Lindley*). *U. S.*

Faba Sancti Ignatii, *Lat.;* Fève de Saint Ignace, *Fr.;* Ignatiusbohne, bittere Fiebernuss, *Germ.;* Fava di Santo Ignazio, *Ital.;* Haba de Santo Ignacio, *Span.*

STRYCHNOS. See NUX VOMICA.

Strychnos Ignatia. Lindley, *Flor. Med.* 530.—*Ignatia amara.* Linn. *Suppl.* This species of Strychnos is a tree of middling size, with numerous long, cylindrical, glabrous, vine-like branches, which bear opposite, nearly sessile, oval, pointed, entire, and very smooth leaves. The flowers are long, nodding, white, tubular, fragrant, and arranged in short axillary racemes. The fruit is of the size and shape of a pear, with a smooth, whitish, ligneous rind, enclosing about twenty seeds, embedded in a dry medullary matter, and lying one upon the other. The seeds are the part used. The tree is a native of the Philippine Islands, where the seeds were highly esteemed as a medicine, and, having attracted the attention of the Jesuits, were honoured with the name of their founder.

Properties. The seeds are about an inch long, rather less in breadth, still less in thickness, convex on one side, obscurely angular, with two, three, or four faces on the other, and marked at one end with a small depression indicating their point of attachment. They are externally of a pale-brown colour, apparently smooth, but covered in fact with a short down or efflorescence, which may be removed by scraping them with a knife. They are somewhat translucent, and their substance is very hard and horny. They have no smell, but an excessively bitter taste. To Pelletier and Caventou they yielded the same constituents as nux vomica, and, among them, 1·2 per cent. of strychnia. Analyzed by Mr. J. M. Caldwell, they were found to contain the two alkaloids, strychnia and brucia, combined with igasuric acid, and, besides these, a volatile principle, extractive,

* *Japanese Isinglass.* Under this name, which, however, is altogether inappropriate, a substance has been recently brought into the English market, prepared from sea-weeds in China and Japan. Two forms of it are described by Mr. Hanbury, one in irregularly four-sided sticks, about eleven inches long, very light and porous, the other in long shrivelled strips about one-eighth of an inch thick. It is translucent, yellowish-white, without smell or taste, insoluble in cold water, but swelling up and softening under its influence, and dissolved in great measure by boiling water, with which it gelatinizes on cooling. The peculiarities of this substance are owing to a principle denominated *gelose* by Payen, which resembles gelatin in its gelatinizing property, but differs in its chemical relations, and is probably peculiar. It resembles the carrageenin of Irish moss, but has a greater gelatinizing power. The jelly formed by dissolving it in boiling water, and allowing the solution to cool, requires a higher temperature to liquefy it than gelatin jelly, and does not melt in the mouth. Gelose differs from gelatin in not being precipitated by tannic acid, and from rice jelly in not being rendered blue by iodine. Japan isinglass is used for the same purposes as that of animal origin. It is derived, according to Mr. Hanbury, from different species of various genera of sea-weed, and especially *Gelidium corneum.* (See *Am. Journ. of Pharm.*, July, 1860, p. 354.)—*Note to the twelfth edition.*

gum, resin, colouring matter, fixed oil, and bassorin, but no starch or albumen. (*Am. Journ. of Pharm.*, July, 1857, p. 298.) In consequence of the relatively larger proportion of strychnia which they yield, they have been considerably used instead of nux vomica, in the preparation of that alkaloid.

Medical Properties and Uses. MM. Magendie and Delile have proved that ignatia acts on the human system in the same manner as nux vomica. In the Philippines, the seeds have been employed for the cure of obstinate intermittents, and in numerous other diseases. It is probable that, in small doses, they act as a tonic. Recently, an extract prepared from them has been much used, having been first introduced into notice empirically, under the name of *ignatia amara*. It has been employed chiefly in cases of debility of the digestive organs, or general defect of nervous power; but, being in all probability identical in its effects with a similar preparation of nux vomica, though somewhat stronger, it may be used for all the therapeutic purposes to which the latter medicine is applied. It is scarcely necessary to observe that so energetic a substance should never be taken without regular medical supervision, as it may prove, if abused, a terrific poison. An extract is directed, in the present edition of the U. S. Pharmacopœia. (See *Extractum Ignatiæ Alcoholicum*.) The dose may be from half a grain to a grain and a half, in pill, three times a day. A *tincture* may also be used. Prof. Procter has given the following formula for its preparation. Powder four troyounces of the beans coarsely by grinding, or in a mortar, add two fluidounces of water to the powder in a bottle, and heat by a water-bath until it swells up; then pour on it half a pint of alcohol, and, having continued the heat for three hours, put the whole into a percolator, and displace with alcohol until a pint of tincture is obtained. Or, half an ounce of the extract may be dissolved in a pint of alcohol. The commencing dose, corresponding with that above stated of the extract, would be about sixteen minims.

INULA. *U. S. Secondary.*

Elecampane.

The root of Inula Helenium. *U. S.*

Aunée, *Fr.*; Alantwurzel, *Germ.*; Enula Campana, *Ital.*, *Span.*

INULA. *Sex. Syst.* Syngenesia Superflua.—*Nat. Ord.* Compositæ-Asteroideæ, *De Cand.* Asteraceæ, *Lindley.*

Gen. Ch. Receptacle naked. *Seed-down* simple. *Anthers* ending in two bristles at the base. *Willd.*

Inula Helenium. Willd. *Sp. Plant.* iii. 2089; Woodv. *Med. Bot.* p. 64, t. 26. Elecampane has a perennial root, and an annual stem, which is round, furrowed, villous, leafy, from three to six feet high, and branched near the top. The leaves are large, ovate, serrate, crowded with reticular veins, smooth and deep-green upon the upper surface, downy on the under, and furnished with a fleshy midrib. Those which spring directly from the root are petiolate, those of the stem sessile and embracing. The flowers are large, of a golden-yellow colour, and stand singly at the ends of the stem and branches. The calyx exhibits several rows of imbricated ovate scales. The florets of the ray are numerous, spreading, linear, and tridentate at the apex. The seeds are striated, quadrangular, and furnished with a simple somewhat chaffy pappus.

This large and handsome plant is a native of Europe, where it is also cultivated for medical use. It has been introduced into our gardens, and has become naturalized in some parts of the country, growing in low meadows, and on the roadsides, from New England to Pennsylvania. It flowers in July and August. The roots, which are the officinal part, should be dug up in autumn, and in their second year. When older they are apt to be stringy and woody.

The fresh root of elecampane is very thick and branched, having whitish cylindrical ramifications, furnished with thread-like fibres. It is externally brown, internally whitish and fleshy; and the transverse sections present radiating lines.

The dried root, as found in the shops, is usually in longitudinal or transverse slices, and of a grayish colour internally. The smell is slightly camphorous, and, especially in the dried root, agreeably aromatic. The taste, at first glutinous, and compared to that of rancid soap, becomes, upon chewing, warm, aromatic, and bitter. Its medical virtues are extracted by alcohol and water, the former becoming most strongly impregnated with its bitterness and pungency. A peculiar principle, resembling starch, was discovered in elecampane by Valentine Rose, of Berlin, who named it *alantin;* but the title *inulin*, proposed by Dr. Thomson, has been generally adopted. It differs from starch in being deposited unchanged from its solution in boiling water when the liquor cools, and in giving a yellowish instead of a blue colour with iodine. It has been found in the roots of several other plants. It may be obtained white and pure by precipitating a concentrated decoction with twice its volume of alcohol, dissolving the precipitate in a little distilled water, treating the solution with purified animal charcoal, and again precipitating with alcohol. (See *Am. Journ. of Pharm.*, xxvii. 69.) Besides this principle, elecampane contains, according to John, a white, concrete substance, called *helenin*, intermediate in its properties between the essential oils and camphor, and separable by distillation with water; a bitter extractive, soluble in water and alcohol; a soft, acrid, bitter resin, having an aromatic odour when heated; gum; albumen; lignin; traces of volatile oil; a little wax; and various saline substances. If water is added to a tincture made by boiling the fresh root in alcohol, the liquid becomes turbid, and, in twenty-four hours, long white crystals of pure helenin are formed, leaving very little in solution. (*Archiv. der Pharm.*, lx. 30.)

Medical Properties and Uses. Elecampane is tonic and gently stimulant, and has been supposed to possess diaphoretic, diuretic, expectorant, and emmenagogue properties. By the ancients it was much employed, especially in the complaints peculiar to females; and it is still occasionally resorted to in amenorrhœa. In this country it is chiefly used in chronic diseases of the lungs, and is sometimes beneficial when the affection of the chest is attended with weakness of the digestive organs, or with general debility. From a belief in its deobstruent and diuretic virtues, it was formally prescribed in chronic engorgements of the abdominal viscera, and the dropsy to which they so often give rise. It has also been highly recommended both as an internal and external remedy in tetter, psora, and other diseases of the skin. The usual modes of administration are in powder and decoction. The dose of the powder is from a scruple to a drachm. The decoction may be prepared by boiling half an ounce of the root in a pint of water and given in the dose of one or two fluidounces. W.

IODINIUM. *U. S.*

Iodine.

Off. Syn. IODUM. *Br.*

Iode, *Fr.;* Jod, *Germ.;* Iodina, *Ital., Span.*

The Iodine of the U. S. and Br. Pharmacopœias is considered as pure; and in both the tests are given by which its purity may be determined. As one of these tests, the latter Pharmacopœia states that "12·7 grains, dissolved in an ounce [fluidounce] of water containing 15 grains of iodide of potassium, require for complete discoloration 1000 grain-measures of the *volumetric solution of hyposulphite of soda.*"

Iodine is a non-metallic element, discovered in 1812 by Courtois, a soda manufacturer of Paris. It exists in certain marine vegetables, particularly the fuci or common sea-weeds, which are its most abundant natural source. It has been detected in some fresh-water plants, among which are the water-cress, brooklime, and fine-leaved water-hemlock; also in the ashes of tobacco, and of Honduras sarsaparilla. (*Chatin.*) It has been found in the beet-root of the Grand Duchy of Baden. (*Lamy.*) M. Chatin announced the presence of iodine in the atmosphere and in rain-water; but the negative experimental results of Dr. S. Mac-

adam of Edinburgh, of Dr. Lohmeyer of Göttingen, and of M. S. De Luca of Paris, threw doubts on the experiments of M. Chatin, who was supposed to have been misled by the use of reagents containing iodine. Nevertheless, M. Chatin, in answer to the two chemists first named, reasserts the correctness of his results; and declares that he has found iodine in the rain-water of Paris, Versailles, and many other towns in France, while he has failed to discover it in the waters of the Alps and Norwegian mountains. (*Journ. de Pharm.*, Avril, 1860, p. 259.) Dr. Macadam detected a trace of iodine in 100 gallons of water used for domestic purposes in Edinburgh, in several of the domestic animals, and in man. He detected it also in potatoes, beans, peas, wheat, barley, and oats. (*Pharm. Journ.*, Nov. 1854, p. 235.) Iodine is moreover found in the animal kingdom, as in the sponge, the oyster, various polypi, cod-liver oil, and eggs; and, in the mineral kingdom, in sea-water in minute quantity, in certain salt springs, as iodide of silver in a rare Mexican mineral, in a zinc ore of Silesia, in native nitrate of soda, and in some kinds of rock salt. It has been detected by M. Genteles in the aluminous schists of Sweden, by Prof. Sigwart in bituminous slate, by M. Lembert in limestone rocks, and by M. Bussy and M. Duflos in coal. A mineral is said to have been discovered in Chili, consisting of iodide, oxide, and chloride of lead, of which iodine constitutes ten per cent. If, as is reported, this mineral is in large quantities, it may become an important source of iodine. (*Med. and Surg. Reporter*, July 1, 1865, p. 10; from the *Druggists' Circular.*) M. Bussy has obtained iodine, in the proportion of one part in five thousand, from the coal-gas liquor of the gas-works of Paris. It was first discovered in the United States in the water of the Congress Spring, at Saratoga, by Dr. William Usher. It was detected in the Kenhawa saline waters by the late Professor Emmet; and it exists in the bittern of the salt-works of western Pennsylvania, in the amount of about eight grains to the gallon. In sea-weeds the iodine exists in the state probably of iodide of sodium. In different countries, sea-weeds are burned for the sake of their ashes; the product being a dark-coloured fused mass called *kelp*. This substance, besides carbonate of soda and iodide of sodium, contains more or less common salt, chloride of potassium, sulphate of soda, &c. The deep-sea fuci contain the most iodine; and, when these are burned at a low temperature for fuel, as is the case in the island of Guernsey, their ashes furnish more iodine than ordinary kelp. (*Graham.*) According to Dr. Geo. Kemp, the laminarian species, especially *Laminaria digitata*, *L. saccharina*, and *L. bulbosa*, which are deep-water sea-weeds, and contain more potassium than sodium, are particularly rich in iodine. In a paper on the extraction of iodine from sea-weeds, Dr. Kemp makes many useful suggestions, having chiefly in view the prevention of the waste of the element, which takes place in the ordinary kelp process. (*Chem. Gaz.*, July 1, 1850.)*

* Dr. Wallace and Mr. Lamont, of Glasgow, in a paper describing a new method of estimating the proportion of iodine in kelp, state that, in parcels from the West Highlands, they had obtained from 0·162 to 0·175 per cent., which is a much larger product than that mentioned in the text; but they operated on small quantities, which yield a larger percentage than is procured by operations on a large scale, in consequence of the loss necessarily incurred in them. (*Chem. Gaz.*, April 1, 1859, p. 137.) A complete analysis of kelp by Mr. Lamont is contained in the same journal. (June 1, 1859, p. 210.) To prevent the loss of iodine by volatilization in the burning of sea-weeds, Dr. Wallace proposes to extract all the iodine compounds they contain by boiling them with water, and evaporating the decoction. The extract thus obtained is to be treated as kelp.

New method of preparing kelp. As the preparation of kelp for the extraction of iodine may possibly become a source of profitable occupation upon the sea-coast of some parts of the United States, the following observations, contained in a paper on its manufacture, read by Mr. Ed. C. C. Stanford before a meeting of the British Pharmaceutical Society, may be of advantage. The present process, employed in the Highlands of Scotland, is on various accounts objectionable, but especially from the waste of iodine attending it. From the high heat to which the sea-weed is exposed in its conversion into ashes, much of the iodine is driven off. From the same cause, the sulphates are deoxidized, and converted into sulphurets, the separation of which in the process for extracting the iodine necessitates a large expenditure of sulphuric acid. Besides, there is an entire loss of the

Preparation. Iodine is obtained from kelp, and in Great Britain is manufactured chiefly at Glasgow. The kelp, which on an average contains a 224th part of iodine, is lixiviated with water, in which about half dissolves. The solution is concentrated to a pellicle and allowed to cool; whereby nearly all the salts, except iodide of sodium, are separated, they being less soluble than the iodide. The remaining liquor, which is dense and dark-coloured, is made very sour by sulphuric acid, which causes the evolution of carbonic acid, sulphuretted hydrogen, and sulphurous acid, and the deposition of sulphur. The liquor is then introduced into a leaden still, and distilled with deutoxide of manganese into a series of glass receivers, inserted into one another, in which the iodine is condensed. In this process the iodide of sodium is decomposed, and the iodine evolved; and the sulphuric acid, deutoxide of manganese, and sodium unite, so as to form sulphate of protoxide of manganese and sulphate of soda.

The British Pharmacopœia of 1864 purified iodine as follows. "Take of Iodine of Commerce *one ounce*. Introduce the Commercial Iodine into a porcelain capsule of a circular shape, cover this as accurately as possible with a glass matrass filled with cold water, and apply to the capsule the heat of boiling water for twenty minutes. Let the matrass be now removed, and should colourless acicular prisms of a pungent odour be found attached to its bottom, let them be separated from it. This being done, the matrass is to be restored to its previous position, and a gentle and steady heat (that of a gas lamp answers well) applied, so as to sublime the whole of the iodine. Upon now allowing the capsule to cool, and lifting off the matrass, the purified product will be found attached to the bottom of the latter. When separated it should be immediately enclosed in a bottle furnished with an accurately ground stopper." *Br.*

In this process, which is that of the former Dublin Pharmacopœia, a short preliminary sublimation by the heat of a water-bath is ordered, in which the bottom of a glass matrass filled with cold water is the refrigerator. The object of this is to separate any iodide of cyanogen that may happen to be present.

volatile matters escaping during combustion, which might be utilized by an improved process. The plan suggested by Mr. Stanford is to carbonize the weed in close vessels. The following is a summary of his method, as specified in a patent taken out in Great Britain and France.

The sea-weeds, which may be gathered at all seasons, should be well dried, and then compressed into cakes of convenient size. These are put into large cylindrical vessels of wrought iron heated from without, placed vertically, with the base and upper end conical, and with arrangements for introducing and withdrawing the charge. The retorts, thus formed, are furnished at the upper end with pipes which carry the volatilized products to an iron main, whence they pass through a series of ordinary iron pipe condensers, from which the uncondensed matter passes through a pair of scrubbers to a gasometer. When sufficiently charred, the contents of the retorts are withdrawn into closely-covered iron boxes, which are to be removed to a convenient place. When cool, the charcoal is lixiviated like kelp, and the solution treated in the ordinary manner for separating the iodine. The lixiviated charcoal may be used for heating the retort, and the gas collected in the gasometer for lighting the factory, or for producing heat. The ashes resulting from the burning of the charcoal is a valuable manure. The condensed products of the distillation may be used for obtaining muriate of ammonia, and utilized in various other ways. (*Pharm. Journ.*, April, 1862, p. 502.)—*Note to the twelfth edition.*

M. Ed. Moride proposes the following plan, which he thinks has advantages over those previously in use. He contents himself with carbonizing the plants, fresh or dry, in the locality where collected, by means of a little portable furnace adapted to the purpose. He then lixiviates the charcoal in a percolation apparatus, concentrates the liquid obtained by means of vapour, withdraws the sulphates of potassa and the chlorides thrown down, and then, after having added a hypochlorite or hyponitric acid, treats the liquor with benzine in a special apparatus, arranged so that the benzine takes the iodine from the liquor, yields it afterwards to potassa or soda, and, being itself recovered, may be used again indefinitely. The mixed alkaline iodides and iodates are precipitated by muriatic acid, or, still better, by the chlorine liquors remaining in the manufacture of bromine. The iodine obtained is then dried and brought to the state of mass, as in commerce. The bromine present in the liquors, deprived of iodine by benzine, may be withdrawn either by adding sulphuric acid and black oxide of manganese and distilling, or by eliminating it directly, in the liquid state, in the liquors concentrated and made very acid. (*Journ. de Pharm. et de Chim.*, 4e sér., iv. 165, A. D. 1866.)—*Note to the thirteenth edition.*

This impurity is sometimes present in considerable amount. Klobach obtained from eighty avoirdupois pounds of commercial iodine twelve ounces of this iodide, which is in the proportion of nearly one per cent. (*Chem. Gaz.*, April 15, 1850.) Should the matrass, upon its removal, have attached to its bottom white acicular crystals, these will be the iodide in question, and must be rejected. The matrass having been replaced, heat is again applied until the whole of the iodine has sublimed, and attaches itself to the cool bottom of the matrass.

Water has sometimes been found in iodine to the extent of 15 or 20 per cent. If considerable, it is easily discovered by the iodine adhering to the inside of the bottle. M. Bolley estimates its amount by rubbing together, until the smell of iodine disappears, 30 grains of iodine with about 240 of mercury, in a small weighed porcelain dish, using a small weighed agate pestle. When complete combination has been effected, the whole is placed in a water-bath to dissipate the water. The loss of weight gives the amount of water in the iodine. (*Chem. Gaz.*, Mar. 15, 1853, p. 118.) The presence of water is injurious only as it renders all the preparations of iodine weaker than they should be. In the former Ed. Pharmacopœia, directions were given to dry it, by placing it "in a shallow basin of earthenware, in a small confined space of air, with ten or twelve times its weight of fresh-burnt lime, till it scarcely adheres to the inside of a dry bottle."

Properties. Iodine is a soft, friable, opaque substance, in the form of crystalline scales, having a bluish-black colour and metallic lustre. It possesses a peculiar odour, somewhat resembling that of chlorine, and a hot, acrid taste. Applied to the skin, it produces a yellow stain, which soon disappears Its sp. gr. is 4·9. It is a volatile substance, and evaporates even at common temperatures. When heated, it volatilizes more rapidly, and, when the temperature reaches 225°, it melts and rises in a rich purple vapour, a property which suggested its name. Its vapour has the sp. gr. 8·7, being the heaviest aëriform substance known. If inhaled mixed with air, it excites cough and irritates the nostrils. When it comes in contact with cool surfaces, it condenses in brilliant steel-gray crystals. Iodine is freely soluble in alcohol and ether, but requires 7000 times its weight of water to dissolve it. If water stands on iodine for some time, especially in a strong light, it apparently dissolves more iodine; but the result depends upon the formation of hydriodic acid, in a solution of which iodine is more soluble than in water. The solution of iodine in water has no taste, a feeble odour, and a light-brown colour; in alcohol or ether, is nearly black. Its solubility in water is very much increased by the addition of certain salts, as the chloride of sodium, nitrate of ammonia, or iodide of potassium; and the same effect is produced, to some extent, by tannic acid Its solution in tannic acid is called *iodo-tannin*, of which MM. Socquet and Guillermond make a syrup for internal, and an aqueous solution for external use. For the formulas, see the *B. and F. Medico-chir. Rev.*, July, 1854, p 181. It is also soluble in glycerin, as ascertained by M. Cap in 1854. In chemical habitudes iodine resembles chlorine, but its affinities are weaker. Its eq. is 126·3, and symbol I. It combines with most of the non-metallic, and nearly all the metallic elements, forming a class of compounds called *iodides*. Some of these are officinal, as the iodides of iron, mercury, lead, potassium, and sulphur. It forms with oxygen one oxide, *oxide of iodine*, and three acids, *iodous*, *iodic*,* and *hyperiodic*, and with hydrogen, a gaseous acid, called *hydriodic acid*.

* Dr. R. H. Brett, of Liverpool, has found that when a small portion of several of the alkaloids, or their salts, is mixed with about an equal portion of iodic acid and a few drops of water, and the mixture gently heated, a succession of distinct explosions, attended by the evolution of gas, takes place. Dr. Brett finds that this phenomenon occurs with all the alkaloids yet tried by him, but not with other classes of organic substances, whether nitrogenous or non-nitrogenous, and thinks it will prove a valuable test for the former. (*Pharm. Journ.*, Nov. 1854.) According to Mr. R. F. Fairthorne, of this city, several of the more poisonous alkaloids, dissolved by the aid of an acid, yield, with the officinal compound solution of iodine, precipitates, insoluble in weak sulphuric, muriatic, or acetic acid. He therefore infers that the above-mentioned solution might prove useful as an antidote to the alkaloids. (*Am. Journ. of Pharm.*, May, 1856.)—*Note to the eleventh edition.*

Tests, &c. Iodine, in most cases, may be recognised by its characteristic purple vapour; but where this cannot be made evident, it is detected unerringly by starch, which produces with it a deep-blue colour. This test was discovered by Colin and Gaultier de Claubry, and is so delicate that it will indicate the presence of iodine in 450,000 times its weight of water. In order that the test may succeed, the iodine, must be free and the solutions cold. To render it free when in combination, as it always is in the animal fluids, a little nitric acid, free from iodine, must be added to the solution suspected to contain it. Thus, in testing urine for iodine, the secretion is mixed with starch, and acidulated with a drop or two of nitric acid; when, if iodine be present, the colour produced will vary from a light purple to a deep indigo blue, according to the amount of the element present. Sometimes, in mineral waters, the proportion of iodine is so minute that the starch test, in connection with nitric acid, gives a doubtful coloration. In such cases, Liebig recommends the addition to the water of a very small quantity of iodate of potassa, followed by a little starch and muriatic acid. Assuming the iodine to be present as hydriodic acid, the liberated iodic acid sets free the iodine of the mineral water, and becomes itself deoxidized, thus increasing the amount of the free iodine ($5HI$ and $IO_5 = 5HO$ and I_6). This test would be fallacious, if iodic acid, mixed with muriatic acid, coloured starch; but this is not the case. Still, Liebig's test is inapplicable in the presence of reducing agents, such as sulphurous acid, which would give rise to free iodine from the test itself, independently of the presence of the element in the water tested. (*Dr. W. Knop.*) Mr. M. Carey Lea proposes chromic acid as a substitute for the nitric, for the liberation of iodine, as a more delicate test. It may be most conveniently applied by first adding starch to the liquid to be tested, and then a little dilute solution of bichromate of potassa, enough to cause a pale-yellow colour, followed by a few drops of muriatic acid. (*Am. Journ. of Sci. & Arts*, A. D. 1866, xlii. 109.) Another test for iodine, proposed by M. Rabourdin, is chloroform, by the use of which he supposes that the element may be not only detected in organic substances, but approximately estimated. Thus, if 150 grains of a solution, containing one part in one hundred thousand of iodide of potassium, be treated with 2 drops of nitric and 15 or 20 of sulphuric acid, and afterwards shaken with 15 grains of chloroform, the latter acquires a distinct violet tint. M. Rabourdin applies his test to the detection of iodine in the several varieties of cod-liver oil. For this purpose he incinerates, in an iron spoon, 50 parts of the specimen of oil with 5 of *pure* caustic potassa, dissolved in 15 of water, and exhausts the cinder with the smallest possible quantity of water. The solution is filtered, acidulated with nitric and sulphuric acids, and agitated with 4 parts of chloroform. After a time the chloroform subsides, of a violet colour more or less deep according to the proportion of iodine present. M. Lassaigne considers the starch test more delicate than that of chloroform. For detecting iodine in the iodides of the metals of the alkalies, he considers bichloride of palladium as extremely delicate, producing brownish flocks of biniodide of palladium. According to M. Moride, benzine is a good test for free iodine, which it readily dissolves, forming a solution of a bright-red colour, deeper in proportion to the amount of iodine taken up. As benzine does not dissolve chlorine or bromine, it furnishes the means of separating iodine from these elements. Mr. D. S. Price has pointed out the nitrites as exceedingly sensitive tests of iodine, combined as an iodide. The suspected liquid is mixed with starch paste, acidulated with muriatic acid, and treated with solution of nitrite of potassa. The iodine is set free, and a blue colour appears, more or less deep, according to the proportion of iodine present. By this test, iodine may be detected in an aqueous solution containing only one in 400,000 parts. A similar test had been previously proposed by M. Grange.

It has been long known that when a mixture of iodine and starch in water is subjected to heat, the blue colour disappears, and, if the heat be not too long continued, so as to volatilize the iodine, or convert it into hydriodic acid, the colour will return on the cooling of the liquid. Various explanations have been

given of this curious fact by Personne and others, but none quite satisfactory, until that by M. Magnes Lahens, which he supports by experiment, that, during the continuance of the heat, the particles of starch and iodine separate to unite again on refrigeration. (*Journ. de Pharm.*, 4e sér., iii. 405.)

Adulterations. Iodine is said to be occasionally adulterated with mineral coal, charcoal, plumbago, and black oxide of manganese. These are easily detected by their fixed nature, while pure iodine is wholly volatilized by heat Herberger found native sulphuret of antimony in one sample, and plumbago in another; and Righini has detected as much as 25 per cent. of chloride of calcium. The presence of iodide of cyanogen and of water have already been referred to, and the modes of detecting and separating them pointed out. (See *page* 483.) Besides the test given at page 480, the British Pharmacopœia directs that officinal iodine should be soluble in alcohol, ether, and a solution of iodide of potassium, and should sublime without residue, and that the part which first comes over should contain no colourless prisms of a pungent odour.

Medical Properties. Iodine was first employed as a medicine in 1819, by Dr. Coindet, sen., of Geneva. It operates as a general excitant of the vital actions, especially of the absorbent and glandular systems. Its effects are varied by its degree of concentration, state of combination, dose, &c ; and hence, under different circumstances, it may prove corrosive, irritant, desiccant, tonic, diuretic, diaphoretic, and emmenagogue. It probably acts by entering the circulation ; at least it has been proved by numerous observations that, whether taken internally, or applied externally, it always passes with the secretions, particularly the urine and saliva, not, however, uncombined, but in the state of hydriodic acid or an iodide. Cantu detected it not only in the urine and saliva, but also in the sweat, milk, and blood. According to Dr. John C. Dalton, jun., of New York, iodine, taken in a single moderate dose, appears in the urine in thirty minutes, and may be detected for nearly twenty-four hours. In two cases in which large doses of iodide of potassium had been taken for six or eight weeks, and the medicine intermitted, all trace of iodine disappeared from the urine in eighty-four hours. From this observation Dr. Dalton infers, as Becquerel had previously done, that iodine does not accumulate in the system, and that, therefore, the effect of moderate doses is probably equal to that of large ones, the excess constantly passing off, principally by the kidneys. But iodine is not, like iron, a reconstructive element, and does not act by supplying anything to the system. Hence its rapid elimination by the urine may have a therapeutic effect; and this effect may be in proportion to the amount eliminated. It is certainly not an unreasonable supposition that the medicine, while passing off in larger or smaller quantity by the kidneys, may carry with it more or less abnormal material, and thus act as a sorbefacient.

The tonic operation of iodine is evinced by its increasing the appetite, which is a frequent effect of its use. Salivation is occasionally caused by it, and sometimes soreness of the mouth only. In some cases, pustular eruptions and coryza have been produced; especially when the remedy has been given in the form of iodide of potassium. In an overdose it acts as an irritant poison. Doses of two drachms, administered to dogs, have produced irritation of the stomach, and death in seven days; and the stomach was found studded with numerous little ulcers of a yellow colour. From four to six grains in man, cause a sense of constriction in the throat, sickness and pain at the stomach, and at length vomiting and colic. Even in medicinal doses, it sometimes causes alarming symptoms ; such as fever, restlessness, disturbed sleep, palpitations, excessive thirst, acute pain in the stomach, vomiting and purging, violent cramps, frequent pulse, and, finally, progressive emaciation, if the medicine be not laid aside. The condition of the system, marked by these effects of iodine, is called *iodism*. Upon their first appearance, the remedy should be discontinued, and a milk diet prescribed. Though iodism, when it occurs, is generally the result of incautious doses of the medicine too long continued, yet it sometimes arises, under other circumstances, from causes not well understood. On the other hand, large

doses have been given for a long time with perfect impunity. Dr. Lugol, of Paris, never observed alarming effects to arise from iodine, given in the doses and in the state of dilution in which he prescribed it. On the contrary, many of his patients gained flesh, and improved in general health.

Testimony is not wanting to the effect, that a long course of the remedy has in some instances occasioned absorption of the mammæ and wasting of the testicles. Yet Dr. T. H. Silvester, who had the opportunity of making extensive observations in St. Thomas's Hospital, London, on the effects of iodine in the form of iodide of potassium, did not meet with a single instance of atrophy or absorption of these glands. Numerous cases of syphilitic periostitis were successfully treated, enlarged testicles from a syphilitic cause reduced, and chronic induration of the inguinal glands removed; but in no case was atrophy or absorption of the breast or testicle observed. It would thus appear that iodine, as a general rule, does not affect the healthy glands, but acts upon abnormal material, such as tumours, enlargements, and thickenings.

The variable operation of iodine may to some extent be accounted for by the more or less amylaceous character of the food; starch having the property of uniting with iodine and rendering it mild. Dr. Lebert, who has practised both in Switzerland and France, explains the fact in another way. Under his observation, the accidents produced by iodine, with scarcely an exception, were in those cases of goitre in which the remedy acted rapidly in removing the tumour; while in scrofulous, tuberculous, and syphilitic patients, free from goitre, though the medicine was given in considerable doses, no injury to the system ensued. He supposes that the bad effects, in the goitre cases, arose from the too prompt absorption of the abnormal material of the tumour, which, entering the circulation in the course of its elimination, produced the poisonous effect, and not from the iodine itself. (*Ann. de Thérap.*, 1855, p. 228.)

Iodine has been principally employed in diseases of the absorbent and glandular systems. It has been used with success in ascites, especially when connected with diseased liver. It acts most efficiently immediately after tapping. It has proved successful with several British practitioners in ovarian tumours, but has failed in the hands of others. Dr. B. Roemer, of Otter Bridge, Va., reports three cases of ovarian tumour, removed by the combined internal and external use of the remedy. (*Am. Journ. of Med. Sci.*, April, 1857.) In glandular enlargements and morbid growths, it has proved more efficacious than in any other class of diseases. Dr. Coindet discovered its extraordinary power in curing goitre;* and it has been used with more or less advantage in enlargements and indurations of the liver, spleen, mammæ, testes, and uterus. In hepatic affections of this kind, where mercury has failed or is inadmissible, iodine is our best resource. In chronic diseases of the uterus, with induration and enlargement, and in hard tumours of the cervix and indurated puckerings of the edges of the os tincæ, iodine has occasionally effected cures, administered internally, and rubbed into the cervix, in the form of ointment, for ten or twelve minutes every night. The emmenagogue power of iodine has been noticed by several practitioners. It has been recommended in gleet; also in gonorrhœa and leucorrhœa, after the inflammatory symptoms have subsided. In the latter complaint, iodine, rendered soluble by iodide of potassium, has been used successfully, in the form of injection, by Dr. T. T. Russell, of Pattersonville, La. He joined to the local treatment, the internal use of the tincture of chloride of

* M. Chatin, finding, according to his observations, a great variation in the amount of iodine in the air, water, and soil of different localities, has founded on this supposed fact an explanation of the prevalence of goitre and cretinism in some places, and their absence in others. Thus, in certain parts of France, near Paris, which he calls the Paris zone, the amount of iodine thus distributed is comparatively large, and goitre and cretinism are unknown; while, in the Alpine valleys, where only one-tenth the amount of iodine is found, these affections are endemic. The conclusions of M. Chatin are controverted by the experiments, so far as they go, of M. Lohmeyer, of Göttingen, and of M. Kletzinsky, of Vienna, who failed to detect iodine in the air of those cities, the inhabitants of which are free from goitre. (*Note to the eleventh edition.*)

iron. (*Am. Journ. of Med. Sci.*, April, 1854.) In pseudo-syphilis, mercurial cachexy, and the poisonous effects of lead, it is one of our best remedies, in the form of iodide of potassium. In the same form, it is a favourite remedy in chronic rheumatism, and, by Gendrin, was employed in acute gout, with the supposed effect of cutting short the fits. Dr. Manson, as early as 1825, recorded cases of the efficacy of iodine in several nervous diseases, such as chorea and paralysis In various scaly eruptions, the internal and external use of the remedy is very much relied on. The tincture has been strongly recommended in diabetes by M. Bérenger-Féraud. (*Ann. de Thérapeutique*, 1866, p. 243.)

But it is in scrofulous diseases that the most striking results have been obtained by the use of iodine. Dr. Coindet first directed attention to its effects in scrofula, and Dr. Manson reported a number of cases of this affection, in a large proportion of which the disease was either cured or meliorated. The latter physician derived benefit from its use also in white swelling, hip-joint disease, and distortions of the spine, diseases admitted to be connected with the scrofulous taint. We are indebted, however, to Dr. Lugol for the most extended researches in relation to the use of iodine in scrofula. This physician began his trials in the hospital Saint Louis, in 1827, and published his results in three memoirs, in 1829, 1830, and 1831. The scrofulous affections, cured by Dr. Lugol by the iodine treatment, were glandular tubercles, ophthalmia, ozæna, lupus, and fistulous and carious ulcers.

After the publication of Dr. Lugol's memoir, his practice was imitated and extended. Dr. Bermond, of Bordeaux, succeeded with the iodine treatment in enlarged testicle from a venereal cause, scrofulous ophthalmia of six years' duration, and scrofulous ulcers and abscesses of the cervical and submaxillary glands. In numerous other cases of scrofula under his care, iodine proved beneficial; though, before its commencement, the cases underwent no improvement. The only peculiarity in Dr. Bermond's treatment was that, in some cases, he associated opiates with the iodine. In ophthalmia, the collyrium employed by him consisted of *thirty drops* of tincture of iodine, *thirty-six* of laudanum, and *four fluidounces* of distilled water. When the local application of the iodine created much pain or rubefaction, he found advantage from combining extract of opium with it. A plaster, which proved efficacious as an application to an enlarged parotid, consisted of lead plaster (diachylon) and iodide of potassium, each, *four parts*, and iodine and extract of opium, each, *three parts*. In confirmation of Dr. Bermond's statements, M. Lemasson published a number of cases, proving the efficacy of a combination of iodine and opium in the local treatment of scrofulous ulcerations. One of the combinations which he employed consisted of *fifteen grains* of iodine, *a drachm* of iodide of potassium, and *two drachms* of Rousseau's laudanum, made into an ointment with *two ounces* of fresh lard.

The most eligible form of iodine for internal administration is its solution in water, aided by iodide of potassium. This is the form preferred by Dr. Lugol; and such a solution is among the preparations of the U. S. Pharmacopœia. The solutions employed by Dr. Lugol contained one part of iodine and two of iodide of potassium; and the doses given by him were equivalent to half a grain of iodine daily for the first fortnight, three-quarters of a grain daily for the second and third fortnights, one grain daily during the fourth and fifth, and, in some cases, a grain and a quarter daily for the remainder of the treatment; always largely diluted. (See *Liquor Iodinii Compositus.*) The tincture of iodine is not eligible for internal use; for, when freshly prepared, the iodine is precipitated from it by dilution with water; and, as a consequence, the irritating solid iodine will come in contact with the stomach when the dose is swallowed. The same objection is not applicable to the compound tincture, or to the simple tincture after having been long kept.

The favourable results obtained by Dr. Lugol, in the treatment of scrofulous diseases by the iodine preparations, are so numerous as to leave no doubt of their efficacy in these affections. To judge fairly, however, of his results, it is not sufficient to give iodine; but it should be given in the manner in which it

was employed by him. We can readily conceive that a dilute aqueous solution of iodine may act differently from the tincture; for a therapeutical agent may in a dilute form be introduced gradually into the current of the circulation, and thus produce important alterative effects; while in a concentrated form it may create irritation of the stomach without being absorbed, and thus prove mischievous. A case in point is furnished by natural mineral waters, which, though generally containing a minute proportion of saline matter, often produce remedial effects which cannot be obtained by their constituents in larger doses. These views are confirmed and extended by M. Benj. Belli, in an able paper on the efficacy of a certain dilution of medicines, illustrated by examples drawn from iodine, bromine, iron, antimony, belladonna, oil of turpentine, and common salt, published in the *Annuaire de Thérapeutique* for 1857, p. 270. They correspond also with the views of Dr. A. Buchanan, of Glasgow, who gives iodine in the form of iodide of starch, and of hydriodic acid largely diluted with water. (See *Iodide of Starch* and *Hydriodic Acid* in *Part III.*)

A mode of safely bringing and maintaining the system under the influence of iodine, proposed by M. Boinet, and called by him *iodic alimentation*, is to mix the medicine with the food, as with bread and other farinaceous substances, so that the patient may take daily a due quantity, which, with this mode of administration, may be large, if desirable, without inconvenience. The compound formed with starch by the iodine, while destitute of irritating properties, is taken readily into the system, and produces the remedial effects of the medicine.

M. Marchal (de Calvi), under the impression that cod-liver oil owed its chief virtue to the presence of iodine, proposed, in 1848, to prepare an *iodized oil*. Following out this proposal, M. Personne devised the following formula. Five parts of iodine are mixed with a thousand of almond oil, and the mixture is subjected to a jet of steam, until decolorized. The same operation is repeated with five additional parts of iodine. The oil is then washed with a weak alkaline solution, to remove the hydriodic acid, developed in the process. By this mode of proceeding, it may be presumed that the iodine is intimately united with the oil, along with which it would find an easy entrance into the system; and that, while about half of the iodine is lost as hydriodic acid, the remainder takes the place of the hydrogen eliminated from the oil. In 1851, the French Academy appointed MM. Guibourt, Soubeiran, Gibert, and Ricord, to report upon the therapeutic value of a definite combination of iodine and oil. The reporter (Guibourt) approved of M. Personne's process; and MM. Gibert and Ricord reported favourably of the therapeutic effects of the preparation. M. Personne's iodized oil differs little in appearance and taste from almond oil, and is easily taken alone or in emulsion. The usual dose is two fluidounces daily, which may be increased to three fluidounces or more. (*Am. Journ. of Med. Sci.*, xxiii. 502.)

M. Berthé and M. Lepage have objected to M. Personne's iodized oil, that it is of variable iodine strength, and that it is liable to become rancid, in consequence of the use of steam in its preparation. M. Berthé makes an iodized oil, which he alleges to be free from these objections, by heating, to about 176°, five parts of iodine with a thousand parts of almond oil, in a water-bath, until decoloration shall have taken place. The resulting oil is colourless, perfectly transparent, without odour or rancidity, not acted on by starch, and of a constant composition. To shorten the time in preparing the oil, M. Lepage dissolves the iodine in three times its weight of ether, before adding it to the oil, and briskly shakes the mixture for eight or ten minutes. The preparation is then heated in a water-bath, to decolorize it and drive off the ether. M. Hugounenq objects to this process that, if the oil be completely deprived of the odour of ether, the heating must be continued for several hours. He also objects to any process which requires the continued application of heat, as rendering the oil liable to become quickly rancid. His plan is to rub up the iodine, for five or six minutes, in a porcelain mortar, with a small portion of the oil, and then gradually to add the remainder. A red limpid liquid is obtained, which may be completely decolorized by exposure for fifteen minutes to the sun's rays. Iodized oil, thus pre-

pared, has the odour and taste of almond oil, is not more liable to become rancid than the pure oil, and is free from hydriodic acid. (*Journ. de Pharm.*, Mars, 1856.) From the above statements it is not easy to determine which is the best method of preparing iodized oil; but it may be useful to state that the preparation may be made with good olive oil, instead of the more expensive almond oil.

The external treatment by iodine may be divided into general and topical. By its use in this way it does not create a mere local effect; but, by its absorption, produces its peculiar constitutional impression. The external treatment, when general, consists in the use of the *iodine bath*. This for adults should contain from two to four drachms of iodine, with double that quantity of iodide of potassium, dissolved in water, in a *wooden* bath tub; the proportion of the water being about a gallon for every three grains of iodine employed. The quantity of ingredients for the baths of children is one-third as much as for adults, but dissolved in about the same proportional quantity of water. The quantity of iodine and iodide for a bath having been determined upon, it is best to dissolve them in a small quantity of water (half a pint for example), before they are added to the water of the bath; as this mode of proceeding facilitates their thorough diffusion. The iodine baths, which may be directed three or four times a week, usually produce a slight rubefacient effect; but, occasionally, a stronger impression, causing the epidermis to peel off, particularly of the arms and legs. The skin at the same time acquires a deep-yellow tinge, which usually disappears in the interval between the baths.

The topical application of iodine is made by means of several officinal preparations. (See *Unguentum Iodinii* and *Unguentum Iodinii Compositum.*) Besides these, several others have been employed topically. Lugol's *iodine lotion* consists of from two to four grains of iodine, and double that quantity of iodide of potassium, dissolved in a pint of water. It is used as a wash or injection in scrofulous ophthalmia, ozæna, and fistulous ulcers. His *rubefacient iodine solution* is formed by dissolving half an ounce of iodine and an ounce of iodide of potassium in six fluidounces of water. This is useful for exciting scrofulous ulcers, for touching the eyelids, and as an application to recent scrofulous cicatrices, to render them smooth. The rubefacient solution, added to warm water in the proportion of about a fluidrachm to the gallon, makes a convenient local bath for the arms, legs, feet, or hands; and, mixed with linseed meal or some similar substance, it forms a cataplasm useful in certain eruptions, especially where the object is to promote the falling off of scabs. External applications of iodine have been recommended for the removal even of internal plastic exudations, as to the side for example in protracted pleurisy. The rubefacient preparation of iodine at present most commonly employed is the tincture. (See *Tinctura Iodinii.*) The preparation, called *iodine paint*, is a tincture twice as strong as the officinal tincture, and is made by dissolving a drachm of iodine in a fluidounce of alcohol, and allowing the solution to stand in a glass-stoppered bottle for several months before it is used, when it will become thick and syrupy. It is applied with a glass or a camel's-hair brush, in one or more coatings, according to the degree of effect desired. Iodine paint is used as a counter-irritant, with advantage, in pains of the chest; in aphonia, applied to the front of the throat; in chronic pleuritic effusion, or consolidated lung, applied extensively opposite to the diseased part; in periostitis, whether syphilitic, strumous, or the result of injury; in inflammation of the joints; in serous effusion into bursæ; and in the cicatrices of burns. When thus used, it must be borne in mind that the iodine acts also by being absorbed. Another valuable application of it is for the removal of cutaneous nævi. Lugol's *caustic iodine solution* is made of iodine and iodide of potassium, each, an ounce, dissolved in two fluidounces of water. This is used to destroy soft and fungous granulations, and has been employed with decided benefit in lupus. The *Liniment of Iodine* of the British Pharmacopœia is intermediate in strength between the two solutions last mentioned. (See *Linimentum Iodi.*) Another caustic solution of iodine, under the name of *iodized glycerin*, is made by dissolving one part of iodide of potassium in

two parts of glycerin, and adding the solution to one part of iodine, which it completely dissolves. Dr. Max Richter, of Vienna, to whom the credit belongs of having introduced into practice the solution of iodine in glycerin, found this caustic particularly useful in lupus, non-vascular goitre, and scrofulous and constitutional syphilitic ulcers. The solution is applied by means of a hair-pencil to the diseased surface, which must then be covered with gutta-percha paper, fixed at the edges by strips of adhesive plaster, in order to prevent the evaporation of the iodine. The application produces burning pain, which rarely lasts for more than two hours. The dressing is removed in twenty-four hours, and pledgets, dipped in cold water, applied. This iodine caustic is too strong for ordinary local use. A weaker solution is recommended by Dr. Szukits, formed of one part of iodine to five of glycerin, for application to the neck, female breast, abdomen, &c. After four or five paintings it causes excoriation, which requires its discontinuance, and the use of cold applications. A mode of applying iodine locally has been suggested by Dr. R. Greenhalgh, of London, which consists in thoroughly impregnating raw cotton with a solution in glycerin of iodide of potassium and of iodine, in the proportion of two ounces of the former and one ounce of the latter to eight ounces of the menstruum, and then drying the "iodized cotton." It is intended for application to the cervix or os uteri, which is effected through a speculum. (*Lancet*, May 26, 1866, p. 582.)

Iodine is used by injection into various cavities. It has been employed in this way for the cure or relief of hydrocephalus, pleuritic effusion, hydropericardium, ascites, ovarian dropsy, hernia, hydrocele, spina bifida, dropsy of the joints, large cystic bronchocele, and chronic abscesses. Dr. J. M. Winn, of London, reports a case of chronic hydrocephalus in an infant, in which the injection of iodine was used, after tapping, with the apparent effect of retarding the reaccumulation of the fluid. M. Aran, of Paris, tried the same treatment, after tapping, in two cases of pleuritic effusion, and with success in one of the cases. The same physician reports a case of hydropericardium, relieved by twice tapping the sac, and twice injecting it with iodine within the space of twelve days. (*Am. Journ. of Med. Sci.*, April, 1856, p. 499.) Dr. Costes has tried these injections in ascites, but not with encouraging results. In practising them in this disease, Dr. Tessier lays down these rules; *first*, not to empty the peritoneal cavity before performing the injection, as the injected fluid requires dilution by the effused fluid; *second*, to regulate the amount of the injected fluid by the nature of the effused fluid, using twice as much, if the latter is decidedly alkaline and albuminous; and *third*, to practise a tapping some days before the time of injecting, if the abdomen be very voluminous, in order to diminish the peritoneal surface. Iodine injections in ovarian cysts were first practised, in 1846, by Dr. Allison, of Indiana, in a case that terminated favourably. They have been advocated by Prof. Simpson, of Edinburgh, who has employed them in twenty or thirty cases, with variable but encouraging results. A fatal case, however, is recorded by M. Demarquay. (*B. and F. Med.-chirurg. Rev.*, April, 1862, p. 553.) The injection causes little or no pain, if the case is one of genuine *cystic* dropsy. Three cases of the radical cure of hernia by similar injections are reported by M. Jobert, of Paris. (*Am. Journ. of Med. Sci.*, Jan. 1855, p. 241.) In hydrocele iodine has superseded the wine injection formerly employed. It would seem hazardous to inject dropsical joints with a substance so irritating as iodine; and yet Velpeau is stated to have repeatedly used it in these cases with success; and, when the operation has failed, no bad consequences, it is alleged, have followed to the joint. Iodine injections have been employed by Dr. Brainard, of Chicago, in seven cases of spina bifida in all without dangerous symptoms, and in three uncomplicated with hydrocephalus, with the effect of a permanent cure. (*Am. Journ. of Med. Sci.*, July, 1861, p. 67.) In all these cases, the object is to excite a new action in the walls of the cavity, with the effect either of obliterating it by the adhesive inflammation, or of restoring its secreting surface to a healthy condition. Iodine injections have been used with advantage in fistula in ano, effecting the cure, when successful, by exciting adhesive inflammation. This treatment originated with

Mr. Charles Clay, of London, and is praised by Dr. Boinet, who recommends that it should always be tried, before having recourse to the knife. For the mode of preparing iodine injections, see *Tinctura Iodinii*. In order to avoid the staining of the skin by these injections, Dr. Percy Boulton, of London, recommends the addition of carbolic acid, which renders the solution colourless, while in many instances it is useful as an antiseptic. He adds six drops of the acid to a fluidrachm of the compound tincture, and six fluidounces of water. (*N. Y. Med. Record*, Nov. 1, 1867, p. 391.) Whether the iodine would produce the same effect in this altered state can be determined only by experience. Dr. Luton, of Rheims, has found the injection of tincture of iodine into the substance of goitres rapidly successful in effecting cures, with no other disadvantage than some temporary inflammation and swelling of the tumour, which rapidly diminishes. He injects thirty drops of the tincture undiluted. (*Arch. Gén.*, Oct. 1867, p. 438.)

As connected with the subject of iodine injections, it is proper to notice in this place the method of treating serpent bites and other poisoned wounds, proposed by Prof. Brainard, of Chicago. This consists in infiltrating the tissues, where the bite has been inflicted, with from half a drachm to a drachm and a half of a solution, made of five grains of iodine and fifteen of iodide of potassium in a fluidounce of distilled water. A cupping-glass is applied over the wound as soon as possible; and the infiltration is effected by passing beneath the skin, under the edge of the cup, a small trocar, through the cannula of which the solution is injected. Forty experiments were tried with this treatment on pigeons, kittens, and dogs, with generally successful results. Prof. Brainard proposes to extend it to dissection wounds, and all poisoned wounds of a dangerous character. (See Prof. Brainard's *Essay*, &c., Chicago, 1854; also *N. Y. Med. Times*, iii. 210.) Dr E. Harwood treated successfully two cases of snake bite, by simply brushing the tincture of iodine over the wound. (*Boston Med. and Surg. Journ.*, May 17, 1854; from the *N. W. Med. and Surg. Journ.*)

Enemata containing iodine have been used, by several practitioners, in the chronic dysentery and diarrhœa of both adults and children, with decided benefit, a prominent effect being the relief of tenesmus. They are supposed to act locally on ulcers in the colon and rectum, and generally by absorption. The preparation of iodine used was the tincture, rendered miscible with water, without precipitation, by iodide of potassium. The formula recommended by M. Delioux is from three to six fluidrachms of the tincture, with from fifteen to thirty grains of iodide of potassium, dissolved in half a pint of water. The injection should be preceded by an emollient enema to empty the intestine, and should be repeated once or twice daily, gradually increasing its strength. If the pain be severe, a laudanum injection will bring immediate relief.

Dr. Norman Cheevers, of India, strongly recommends iodine gargles in mercurial salivation. The gargle employed by him was composed of from four to ten fluidrachms of the compound tincture of iodine and a pint of water.

Iodine, in the state of vapour, has been employed by inhalation; and the experiments, as yet tried, have been in the treatment chiefly of phthisis and chronic bronchitis. Sir Charles Scudamore, Sir James Murray, and Dr. Corrigan have recommended iodine vapour in phthisis. The plan of Sir Charles is to inhale from a glass inhaler, for ten minutes, two or three times a day, a small portion of a solution of ioduretted iodide of potassium, mixed with a saturated tincture of conium. The ioduretted solution is made by dissolving six grains, each, of iodine and iodide of potassium, in five ounces and three-quarters of distilled water, and a quarter of an ounce of alcohol. The dose, for each inhalation, is from half a drachm to a drachm of the ioduretted solution, gradually increased, with half a drachm of the tincture, added to a portion of water at 120° F., nearly sufficient to half fill the inhaler. M. Piorry employs iodine vapour in phthisis in a different way. He places one or two scruples of iodine, or from one to three fluidounces of the tincture, in a quart jar, and causes the patient to take a deep inspiration from the air in the vessel, one or two hundred times

a day. The patient is made to inhale iodine vapour also during sleep, by placing iodine in several saucers near his pillow, and in numerous vials, attached to his bedstead. Modes of internal treatment, appropriate to each case, were concurrently adopted. M. Piorry avers that, in almost every case subjected to iodine treatment in this way, there was a diminution of the space in which the physical signs of diseased lung were manifested. Many patients with cavities in the lungs were apparently cured. (*Comptes Rendus*, Jan. 24, 1854.) Another application of iodine inhalation is to the cure of aphonia, a plan of treatment suggested by Prof. Pancoast, of this city. A successful case of this affection, of twenty months' standing, treated in this way, is related by Dr. Edward B. Stevens. (*Charleston Med. Journ.*, March, 1854; from the *Iowa Med. Journ.*) Mr. J. Waring-Curran speaks in strong terms of the curative effects of iodine inhalation in diphtheria, having tried it successfully in several seemingly desperate cases. He gives it mixed with an infusion of sage in hot vinegar. (*Lancet*, Sept. 21, 1867, p. 357.)

Another method of administering iodine vapour by inhalation in phthisis and chronic bronchitis has been proposed by M. Barrère, of Toulouse. It consists in forming what he calls *iodized camphor*, which is to be taken like snuff. This is prepared by putting powdered camphor in a snuff-box, with a hundredth part in bulk of iodine, contained in a muslin bag. In the course of a few hours, the substances, by occasional shaking, unite, forming a powder resembling iodine in colour. The difficulty in practising ordinary iodine inhalation depends chiefly on the irritation caused by the vapour, which excites cough and fatigues the patient. According to M. Barrère, this inconvenience is avoided by the use of the iodized camphor. A pinch of it produces sneezing and some smarting in the nostrils; but, when the vapour reaches the lungs, it causes a refreshing sensation, which induces the patient to draw a long and deep breath. (*Ann. de Thérap.*, 1855, p. 232.) The only remaining proposition for iodine inhalation that we have seen, is the one made by M. Huett, who recommends the use of hydriodic ether. This has been employed by him, with success, in a case of phthisis with cavities at the top of the left lung.

Dr. Brainard employs the vapour of iodine, with great advantage, in the treatment of indolent ulcers, first dressing the ulcer with simple cerate spread on lint, then applying over this several layers of lint in which from one to four grains of iodine have been folded, and covering the whole with oiled silk and tin foil, secured by a bandage, so as to prevent the escape of the iodine, which is vaporized by the heat of the body. (*Chicago Med. Journ.*, Jan. 1860.)

Iodine should not be given in solution with quinia or strychnia, as it forms insoluble compounds with these alkaloids. It has even been suggested by Dr. H. W. Fuller, of London, upon this ground, as an antidote to strychnia; but the probability is that the insoluble compound of these substances would by no means be inert in the stomach. (*Lancet*, March 21, 1868, p. 373.)

In cases of poisoning by iodine, the stomach must be first evacuated, and afterwards drinks administered containing an amylaceous substance, such as flour, starch, or arrow-root.

IPECACUANHA. *U. S., Br.*

Ipecacuanha. Ipecacuan.

The root of Cephaëlis Ipecacuanha. *U. S.* The dried root. *Br.*

Ipecacuanha, *Fr.;* Brechwurzel, Ipecacuanha, *Germ.;* Ipecacuana, *Ital., Span.*

The term *ipecacuanha,* derived from the language of the aborigines of Brazil, has been applied to various emetic roots of South American origin.* The U. S. and British Pharmacopœias recognise only that of *Cephaëlis Ipecacuanha;* and no other is known by the name in the shops of this country. Our chief attention will, therefore, be confined to this root, and the plant which yields it; but, as others are employed in South America, are occasionally exported, and may possibly reach our markets mingled with the genuine drug, we shall, in a note, give a succinct account of those which have attracted most attention.

The botanical character of the ipecacuanha plant was long unknown. Pison and Marcgrav, who were the first to treat of this medicine, in their work on the Natural History of Brazil, published at Amsterdam, A.D. 1648, described in general terms two plants; one producing a whitish root, distinguished by the name of white ipecacuanha, the other, a brown root, which answers in their description precisely to the officinal drug. But their account was not sufficiently definite to enable botanists to decide upon the character of the plants. The medicine was generally thought to be derived from a species of *Viola,* which Linnæus designated as *V. Ipecacuanha.* Opinion afterwards turned in favour of a plant, sent to Linnæus by Mutis from New Granada, as affording the ipecacuanha of that country and of Peru. This was described in the *Supplementum* of the younger Linnæus, A. D. 1781, under the name of *Psychotria emetica,* and was long erroneously considered as the source of the true ipecacuanha. Dr. Gomez, of Lisbon, was the first who accurately described and figured the genuine plant, which he had seen in Brazil, and specimens of which he took with him to Portugal; but Brotero, professor of Botany at Coimbra,

* M. Weddell states that the word ipecacuanha is nowhere in Brazil used to designate the Cephaëlis, which is generally called *poaya.* (*Journ. de Pharm.,* 3e sér., xvi. 34.)

with whom he had left specimens, having drawn up a description, and inserted it with a figure in the Linnæan Transactions without acknowledgment, enjoyed for a time the credit due to his countryman. In the paper of Brotero the plant is named *Callicocca Ipecacuanha;* but the term *Callicocca*, having been applied by Schreber, without sufficient reason, to the genus already established and named, has been universally abandoned for the *Cephaëlis* of Swartz, though this, also, it appears, is a usurpation upon the previous rights of Aublet.

CEPHALIS. *Sex. Syst.* Pentandria Monogynia. — *Nat. Ord.* Rubiaceæ, *Juss.* Cinchonaceæ, *Lindley.*

Gen. Ch. Flowers in an involucred head. *Corolla* tubular. *Stigma* two-parted. *Berry* two-seeded. *Receptacle* chaffy. *Willd.*

Cephaëlis Ipecacuanha. Richard, *Hist. Ipecac.* p. 21, t. i.; Martius, *Spec. Mat. Med. Brazil*, p. 4, t. i.; *Curtis's Bot. Mag.*, N. S., vol. xvii. pl. 4083, A.D. 1844. — *Callicocca Ipecacuanha.* Brotero, *Linn. Trans.* vi. 137. This is a small shrubby plant, with a root from four to six inches long, about as thick as a goose-quill, marked with annular rugæ, simple or somewhat branched, descending obliquely into the ground, and here and there sending forth slender fibrils. The stem is two or three feet long; but, being partly under ground, and often procumbent at the base, usually rises less than a foot in height. It is slender; in the lower portion leafless, smooth, brown or ash-coloured, and knotted, with radicles frequently proceeding from the knots; near the summit, pubescent, green, and furnished with leaves seldom exceeding six in number. These are opposite, petiolate, oblong-obovate, acute, entire, from three to four inches long, from one to two broad, obscurely green and somewhat rough on their upper surface, pale, downy, and veined on the under. At the insertion of each pair of leaves are deciduous stipules, embracing the stem, membranous at the base, and separated above into numerous bristle-like divisions. The flowers are very small, white, and collected to the number of eight, twelve, or more, each accompanied with a green bracte, into a semi-globular head, supported upon a round, solitary, axillary footstalk, and embraced by a monophyllous involucre, deeply divided into four, sometimes five or six obovate, pointed segments. The fruit is an ovate, obtuse berry, which is at first purple, but becomes almost black when ripe, and contains two small plano-convex seeds.

The plant is a native of Brazil, flourishing in moist, thick, and shady woods, and abounding most within the limits of the eighth and twentieth degrees of south latitude. According to Humboldt, it grows also in New Granada. It flowers in January and February, and ripens its fruit in May. The root is usually collected during the period of flowering, though equally good at other seasons. By this practice the plant is speedily extirpated in places where it is most eagerly sought. Were the seeds allowed to ripen, it would propagate itself rapidly, and thus maintain a constant supply. Weddell, however, states that the remains of the root, often left in the ground when it is collected, serve the purpose of propagation, each fragment giving rise to a new plant. The root is collected chiefly by the Indians, who prepare it by separating it from the stem, cleaning it, and hanging it up in bundles to dry in the sun. The Brazilian merchants carry on a very brisk trade in this drug. According to Weddell, most of it was, at the time he wrote, A. D. 1851, collected in the interior province of Matto-Grosso, upon the upper waters of the Paraguay, where it was discovered in the year 1824. The chief places of export are Rio Janeiro, Bahia, and Pernambuco. It is brought to the United States in large bags or bales.

Properties. Genuine ipecacuanha is in pieces two or three lines thick, variously bent and contorted, simple or branched, consisting of an interior slender, light straw-coloured, ligneous cord, with a thick cortical covering, which presents on its surface a succession of circular, unequal, prominent rings or rugæ, separated by very narrow fissures, frequently extending nearly down to the central fibre. This appearance of the surface has given rise to the term *annelé*, or *annulated*, by which the true ipecacuanha is designated by French pharmaceutists. The cortical part is hard, horny, and semi-transparent, breaks with a

resinous fracture, and easily separates from the tougher ligneous fibre, which possesses the medicinal virtues of the root in a much inferior degree. Attached to the root is frequently a smoother and more slender portion, which is the base of the stem, and should be separated before pulverization. Pereira has met, in the English market, with distinct bales composed of these fragments of stems, with occasionally portions of the root attached. Much stress has been laid upon the colour of the external surface of the Ipecacuanha root; and diversity in this respect has even led to the formation of distinct varieties. Thus, the epidermis is sometimes deep-brown or even blackish, sometimes reddish-brown or reddish-gray, and sometimes light-gray or ash-coloured. Hence the distinction into *brown*, *red*, and *gray ipecacuanha*. But these are all derived from the same plant, are essentially the same in properties and composition, and probably differ only in consequence of difference in age, place of growth, or mode of desiccation. The colours in fact are often so intermingled, that it would be impossible to decide in which variety a particular specimen should be placed. The *brown* is the most abundant in the packages brought to our market. The *red*, besides the colour of its epidermis, presents a rosy tint when broken, and is said to be somewhat more bitter than the preceding variety. The *gray* is much lighter-coloured externally, usually rather larger, with less prominent rings and wider furrows, and is still more decidedly bitter. Many years since we saw in this market bales of gray ipecacuanha, with very imperfectly developed rings, which were said to have come from Caracas. This commercial variety afterwards quite disappeared; but, under the name of *Carthagena Ipecacuanha*, it would seem to have been again imported into New York. (*Am. Journ. of Pharm.*, xxv. 474.) When the bark in either variety is opaque, with a dull amylaceous aspect, the root is less active. As the woody part is nearly inert, and much more difficult of pulverization than the cortical, it often happens that, when the root is powdered, the portion last remaining in the mortar possesses scarcely any emetic power; and care should be taken to provide against any defect from this cause. The colour of the powder is a light grayish-fawn.

Ipecacuanha has little smell in the aggregate state, but when powdered has a peculiar nauseous odour, which in some persons excites violent sneezing, in others dyspnœa resembling an attack of asthma. The taste is bitter, acrid, and very nauseous. Water and alcohol extract its virtues, which are injured by decoction. Its emetic property resides in a peculiar alkaline principle called *emetia*, discovered by Pelletier in the year 1817. The cortical portion of the brown ipecacuanha, analyzed by this chemist under the erroneous name of *Psychotria emetica*, yielded, in 100 parts, 16 of an impure salt of emetia, which was at first considered the pure emetic principle, 2 of an odorous fatty matter, 6 of wax, 10 of gum, 42 of starch, 20 of lignin, with 4 parts loss. The woody fibre was found to contain only 1·15 per cent. of the impure emetia. M. A. Richard detected in the cortical part traces of gallic acid. The bark of red ipecacuanha was found by Pelletier to contain but 14 per cent. of impure emetia. In addition to these principles, Bucholz found extractive, sugar, and resin; and Erwin Willigk, afterwards, traces of a disagreeably smelling volatile oil, phosphatic salts, and a peculiar acid which he named *ipecacuanhic acid*, and which had previously been mistaken for the gallic. It would seem to belong to the tannic acid group. (See *Am. Journ. of Pharm.*, xxiii. 352.) Good ipecacuanha contains about 80 per cent. of cortical and 20 of ligneous matter.

Emetia, when perfectly pure, is whitish, inodorous, slightly bitter, pulverulent, unalterable in the air, very fusible, sparingly soluble in cold water and ether, more soluble in hot water, and very soluble in alcohol. It is not reddened by nitric acid, forms crystallizable salts with the mineral acids and acetic acid, is precipitated by gallic and tannic acids from its solutions, and contains nitrogen. It is, however, very difficult to procure it in this state of purity, and the proportion afforded by the root is exceedingly small. As originally obtained it was very impure, probably in the condition of a salt, and in this state was directed by the French Codex of 1837. *Impure emetia* is in transparent scales of a brownish-

red colour, almost inodorous, of a bitterish acrid taste, deliquescent, very soluble in water and alcohol, insoluble in ether, precipitated from its solutions by gallic acid and the acetates of lead, but not by tartar emetic or the salts of iron. The Codex directed it to be prepared by evaporating a filtered aqueous solution of an alcoholic extract of ipecacuanha. According to the original method it was obtained by treating powdered ipecacuanha with ether to remove the fatty matter, exhausting the residue with alcohol, evaporating the alcoholic solution to dryness, and subjecting the extract to the action of cold water, which dissolves the emetia with some free acid, and leaves the wax and other matters. To separate the acid, the watery solution is treated with carbonate of magnesia, filtered, and then evaporated. If *pure emetia* is required, magnesia is used instead of the carbonate. The salt is thus decomposed, and the organic alkali, being insoluble, is precipitated with the excess of the earth. The precipitate is washed with cold water, and digested in alcohol, which dissolves the emetia; the alcoholic solution is then evaporated, the residue redissolved in a dilute acid, and the alkali again precipitated by a salifiable base. To deprive it of colour it is necessary to employ animal charcoal. Berzelius has obtained emetia by treating the powdered root with very dilute sulphuric acid, precipitating with magnesia, and treating the precipitate in the manner above directed. Pure emetia has at least three times the strength of the impure.*

* Non-officinal Ipecacuanhas. When ipecacuanha began to be popular in Europe, the roots of several other plants were imported and confounded with the genuine; and the name came at length to be applied to almost all emetic roots derived from America. Several of these are still occasionally met with, and retain the name originally given to them. The two most worthy of notice are the ipecacuanha of New Granada and Peru, and the white ipecacuanha of Brazil. On each of these we shall offer a few remarks.

1. *Peruvian Ipecacuanha. Striated Ipecacuanha. Black Ipecacuanha.* This is the root of *Psychotria emetica*, formerly supposed to produce the genuine Brazilian ipecacuanha. This plant, like the Cephaëlis, belongs to the class and order Pentandria Monogynia, and to the natural order Rubiaceæ of Jussieu. A description of it, sent by Mutis, was published by Linnæus, the younger, in his Supplement. It has since been described in the *Plant. Æquin.* of Humb. and Bonpl.; and has been figured by A. Richard in his History of the Ipecacuanhas, and by Hayne in the eighth volume of his Medical Botany published at Berlin. It is a small shrub, with a stem twelve or eighteen inches high, simple, erect, round, slightly pubescent, and furnished with opposite, oblong-lanceolate, pointed leaves, narrowed at their base into a short petiole, and accompanied with pointed stipules. The flowers are small, white, and supported in small clusters towards the end of an axillary peduncle. The plant flourishes in Peru and New Granada, and was seen by Humboldt and Bonpland growing in abundance near the river Magdalena. The dried root is said to have been exported from Carthagena.

It is cylindrical, somewhat thicker than the root of the Cephaëlis, usually simple, but sometimes branched, not much contorted, wrinkled longitudinally, presenting here and there deep circular intersections, but without the annular rugæ of the true ipecacuanha. The longitudinal direction of the wrinkles has given it the name of *striated ipecacuanha*. It consists of an internal woody cord, and an external cortical portion; but the former is usually larger in proportion to the latter than in the root of the Cephaëlis. The bark is soft and easily cut with a knife, and when broken exhibits a brown, slightly resinous fracture. The epidermis is of a dull reddish-gray colour, which darkens with age and exposure, and ultimately becomes almost black. Hence the root has sometimes been called *black ipecacuanha*. The ligneous portion is yellowish, and perforated with numerous small holes visible by the microscope. Peruvian ipecacuanha is nearly inodorous, and has a flat taste, neither bitter nor acrid. From 100 parts Pelletier obtained 9 of impure emetia, 12 of fatty matter, with an abundance of starch, besides gum and lignin. The dose, as an emetic, is from two scruples to a drachm.

2. *White Ipecacuanha. Amylaceous Ipecacuanha. Undulated Ipecacuanha.* This variety was noticed in the work of Pison; but the vegetable which produced it was not satisfactorily ascertained till a recent date. Gomez, indeed, in the memoir which he published at Lisbon, A. D. 1801, gave a figure and description of the plant; but the memoir was not generally known, and botanists remained uncertain upon the subject. By the travels of M. Saint Hilaire and Dr. Martius in Brazil, more precise information has been obtained; and the white ipecacuanha is now confidently referred to different species of *Richardsonia*, the *Richardia* of Linnæus. *R. scabra*, or *R. Braziliensis* of Gomez, and *R. emetica* are specially indicated by Martius. For the root usually called *white ipecacuanha*, Guibourt has proposed the name of *undulated ipecacuanha*, derived from the peculiar character of the surface, which presents indentations or concavities on one side,

Medical Properties and Uses. Ipecacuanha is in large doses emetic, in smaller, diaphoretic and expectorant, and in still smaller, stimulant to the stomach, exciting appetite and facilitating digestion. In quantities not quite sufficient to vomit, it produces nausea, and frequently acts on the bowels. As an emetic, it is mild but tolerably certain, and, being usually thrown from the stomach by one or two efforts, is less apt to produce dangerous effects, when taken in an overdose, than some other substances of the same class. It is also recommended by the absence of corrosive and narcotic properties.

It was employed as an emetic by the natives of Brazil, when that country was first settled by the Portuguese; but, though described in the work of Pison, it was not known in Europe till 1672, and did not come into use till some years afterwards. John Helvetius, grandfather of the famous author of that name, having been associated with a merchant who had imported a large quantity of ipecacuanha into Paris, employed it as a secret remedy, and with so much success in dysentery and other bowel affections, that general attention was drawn to it; and the fortunate physician received from Louis XIV. a large sum of money and public honours, on the condition that he should make it public.

As an emetic it is peculiarly adapted, by its mildness and efficiency, to cases in which the object is merely to evacuate the stomach, or a gentle impression only is desired; and, in most other cases in which emetics are indicated, it may be advantageously combined with the more energetic medicines, which it renders safer by insuring their discharge. It is especially useful where narcotic poisons have been swallowed; as, under these circumstances, it may be given in almost indefinite doses, with little comparative risk of injury. In dysentery it has been supposed to exercise peculiar powers. As a nauseating remedy it is used in asthma, hooping-cough, and the hemorrhages; as a diaphoretic combined with opium, in numerous diseases. (See *Pulvis Ipecacuanhæ Compositus.*) Its expectorant properties render it useful in catarrhal and other pulmonary affections. It has been given, also, with supposed advantage, in very minute doses, in dyspepsia, and in chronic disease of the gastro-intestinal mucous membrane.

Ipecacuanha is most conveniently administered, as an emetic, in the form of powder suspended in water. The dose is about twenty grains, repeated, if neces-

corresponding with prominences or convexities on the other, so as to give a wavy appearance to the root. It differs little in size from the genuine; is of a whitish-gray colour externally; and, when broken, presents a dull-white farinaceous fracture, offering by the light of the sun shining points, which are nothing more than small grains of fecula. Like the other varieties it has a woody centre. It is inodorous and insipid, and contains, according to Pelletier, a very large proportion of starch, with only 6 per cent. of impure emetia, and 2 of fatty matter. Richard found only 3·5 parts of emetia in the hundred. It is said to be sometimes mixed with the genuine ipecacuanha; but we have discovered none in the bales that we have examined.

According to Martius, different species of *Ionidium* (Viola, Linn.) also produce what is called *white ipecacuanha.* The roots of all the species of Ionidium possess emetic or purgative properties, and some of them have been reported to be equal to the genuine ipecacuanha. The root of *I. Ipecacuanha* is described by Guibourt as being six or seven inches long, as thick as a quill, somewhat tortuous, and exhibiting at the points of flexion semicircular fissures, which give it some resemblance to the root of the Cephaëlis. It is often bifurcated at both extremities, and terminates at the top in a great number of small ligneous stalks. It is wrinkled longitudinally, and of a light yellowish-gray colour. The bark is thin, and the interior ligneous portion very thick. The root has little taste or smell. According to Pelletier, it contains, in 100 parts, 5 of an emetic substance, 35 of gum, 1 of azotized matter, and 37 of lignin. (*Hist. Abrég. des Drogues Simples*, i. 514.)

The root of a species of Ionidium growing in Quito has attracted some attention as a remedy in elephantiasis, under the South American name of *cuichunchulli.* The plant, being considered an undescribed species by Dr. Bancroft, was named by him *I. Marcucci;* but Sir W. Hooker found the specimen, received from Dr. Bancroft, to be identical with the *I. parviflorum* of Ventenat. Lindley thinks a specimen he received under the same name from Quito, to be the *I. microphyllum* of Humboldt. If useful in elephantiasis, it is so probably by its emeto-purgative action. (See *Am. Journ. of Pharm.*, vii. 186.)

The reader is referred to a paper on Ipecacuanha by the late R. E. Griffith, M.D., in the *Journ. of the Philad. Col. of Pharm.* (iii. 181), for a more extended account of the roots which have been used under that name.

sary, at intervals of twenty minutes till it operates. In some persons much smaller quantities prove emetic, and we have known an individual who was generally vomited by the fraction of a grain. The operation may be facilitated, and rendered milder, by draughts of warm water, or warm chamomile tea. An infusion in boiling water, in the proportion of two drachms to six fluidounces, may be given in the dose of a fluidounce repeated as in the former case. For the production of nausea, the dose in substance may be two grains, repeated more or less frequently according to circumstances. As a diaphoretic it may be given in the quantity of a grain; as an alterative, in diseases of the stomach and bowels, in that of a quarter or half a grain two or three times a day. A fluid extract is officinal in the U. S. Pharmacopœia, having been introduced at the late revision of that work. (See *Extractum Ipecacuanhæ Fluidum.*) One fluidrachm of this preparation represents a drachm of the root.

Emetia has been used on the continent of Europe as a substitute, but with no great advantage. Its operation on the stomach is apt to be more violent and continued than that of ipecacuanha; and, if given in overdoses, it may produce dangerous and even fatal consequences. From the experiments of Magendie, it appears to have a peculiar direction to the mucous membranes of the alimentary canal and the bronchial tubes. Ten grains of impure alkali, administered to dogs, were generally found to destroy life in twenty-four hours, and the mucous membranes mentioned were observed to be inflamed throughout their whole extent. The same result took place when emetia was injected into the veins, or absorbed from any part of the body. The dose of impure emetia is about a grain and a half, of the pure not more than half a grain, repeated at proper intervals till it vomits. In proportional doses, it may be applied to the other purposes for which ipecacuanha is used. It will excite vomiting when applied to a blistered surface after the removal of the cuticle.

Dr. Turnbull recommends the external use of ipecacuanha as a counter-irritant. An ointment, made with one part of the powder, one of olive oil, and two of lard, rubbed once or twice a day for a few minutes upon the skin, produces a copious eruption, which continues out for many days, without pain or ulceration. (*London Lancet*, May, 1842.) It has, however, been found by others of little efficacy in the great majority of cases.

IRIS FLORENTINA. *U. S. Secondary.*

Florentine Orris.

The rhizoma of Iris Florentina. *U. S.*

Iris de Florence, *Fr.;* Florentinische Violenwurzel, *Germ.;* Ireos, *Ital.;* Lirio Florentina, *Span.*

Iris. *Sex. Syst.* Triandria Monogynia. — *Nat. Ord.* Iridaceæ.

Gen. Ch. Corolla six-parted; the alternate segments reflected. *Stigmas* petal-shaped. *Willd.*

In all the species belonging to this genus, so far as examined, the roots are more or less acrid, and possessed of cathartic and emetic properties. In Europe, *Iris fœtidissima, I. Florentina, I. Germanica, I. pseudo-acorus,* and *I. tuberosa* have at various times been admitted into use. Of these *I. Florentina* is the only one officinal in this country.

Iris Florentina. Willd. *Sp. Plant.* i. 226; Woodv. *Med. Bot* p. 776, t. 262. The root (rhizoma) of the Florentine Iris is perennial, horizontal, fleshy, fibrous, and covered with a brown epidermis. The leaves spring directly from the root, are sword-shaped, pointed, nerved, and shorter than the stem, which rises from the midst of them more than a foot in height, round, smooth, jointed, and bearing commonly two large white or bluish-white terminal flowers. The calyx is

a spathe with two valves. The corolla divides into six segments or petals, of which three stand erect, and the remaining three are bent backward, and bearded within at their base with yellow-tipped white hairs. The fruit is a three-celled capsule, containing many seeds.

This plant is a native of Italy and other parts of the south of Europe, where it is also cultivated. The root, which is the officinal portion, is dug up in spring, and prepared for the market by the removal of its cuticle and fibres. It is brought from Leghorn in large casks.

Properties. Florentine orris is in pieces of various form and size, often branched, usually about as thick as the thumb, knotty, flattened, white, heavy, of a rough though not fibrous fracture, an agreeable odour resembling that of the violet, and a bitterish, acrid taste. The acrimony is greater in the recent than in the dried root; but the peculiar smell is more decidedly developed in the latter. The pieces are brittle and easily powdered, and the powder is of a dirty-white colour. Vogel obtained from Florentine orris, gum, a brown extractive, fecula, a bitter and acrid fixed oil or soft resin, a volatile crystallizable oil, and vegetable fibre. According to Landerer, the acrid principle is volatile, separating in the form of a stearoptene from water distilled from the root. (*Arch. der Pharm.*, lxv. 302.) In order to preserve the root from the attacks of insects, Mr. Maisch recommends to put a little ether in the bottle in which it may be kept. (*Am. Journ. of Pharm.*, July, 1858, p 310.)

Medical Properties. This medicine is cathartic, and in large doses emetic, and was formerly employed to a considerable extent on the continent of Europe. It is said also to be diuretic, and to have proved useful in dropsies. At present it is valued chiefly for its agreeable odour. Great efficiency, however, has recently been claimed for it as a febrifuge by M. Allisiardi of Saluzzo, in Italy, who states that it has been tried in many cases, and has been found a sure as well as economical substitute for cinchona. For this purpose it is given in the form of watery extract, in the quantity of from two and a half to six drachms, in two doses, with an interval of two hours. (*Ann. de Thérap.*, 1867, p. 126; from *Bullet. Pharmaceut.* of Milan.) It is occasionally chewed to conceal an offensive breath, and enters into the composition of tooth-powders. In the form of small round balls, about the size of a pea, it is used by the French for maintaining the discharge from issues, a purpose to which it is adapted by its odour, by the slight acrimony which it retains in its dried state, and by the property of swelling very much by the absorption of moisture. W

IRIS VERSICOLOR. *U. S. Secondary.*

Blue Flag.

The rhizoma of Iris versicolor. *U. S.*

Iris. See IRIS FLORENTINA.

Iris versicolor. Willd. *Sp. Plant.* i. 233; Bigelow, *Am. Med. Bot.* i. 155. This indigenous species of Iris has a perennial, fleshy, horizontal, fibrous root or rhizoma, and a stem two or three feet high, round on one side, acute on the other, and frequently branching. The leaves are sheathed at the base, sword-shaped, and striated. The flowers are from two to six in number, and are usually blue or purple, though varying much in colour. The capsule has three valves, is divided into three cells, and when mature is oblong, three-sided, with obtuse angles, and contains numerous flat seeds.

The blue flag is found in all parts of the United States, flourishing in low wet places, in meadows, and on the borders of swamps, which it serves to adorn with its large and beautiful flowers. These make their appearance in June. The root is the medicinal portion. The flowers afford a fine blue infusion, which serves as a test of acids and alkalies.

The recent root is without odour, and has a nauseous, acrid taste, which is imparted to water by decoction, and still more perfectly to alcohol. The acri-

mony as well as medicinal activity is impaired by age. If cut when fresh into slices, dried at the temperature of about 100°, and then powdered and kept in bottles excluded from the air, the root retains its virtues unimpaired for a considerable time. (*Andrews.*)

Blue flag possesses the cathartic, emetic, and diuretic properties common to most of its congeners. It was said by Mr. Bartram to be much esteemed by the southern Indians; and Dr. Bigelow states that he has found it efficacious as a purgative, though inconvenient from the distressing nausea and prostration which it is apt to occasion. Dr. M. H. Andrews, of Michigan, has employed it frequently as a cathartic, and found it, when combined with a grain of Cayenne pepper, or two grains of ginger, not less easy and effectual in its operation than the ordinary more active cathartics, and preferable on account of its less disagreeable taste. (*N. Y. Journ. of Med.*, ix. 129.) Dr. Macbride found it useful in dropsy. It is, however, little used by the profession at large, and seldom kept in the shops. It may be given in substance, decoction, or tincture. The dose of the dried root is from ten to twenty grains. Under the unscientific name of *iridin* or *irisin*, which should be reserved for the pure active principle when discovered, the "Eclectics" have for some time used an oleoresin, obtained by precipitating a tincture of the root with water, and mixing the precipitate with an equal weight of some absorbent powder, for which purpose powdered liquorice root would probably answer well. This may be given in the form of pill, in the dose of three or four grains. It is thought to unite cholagogue and diuretic with aperient properties; and a writer in the *London Lancet* states that he has found it to produce effects similar to those caused by a mixture of blue pill, rhubarb, and aloes. (Aug. 30, 1862, p. 239.) W.

JALAPA. *U. S., Br.*

Jalap.

The root of Exogonium Purga (*Bentham*), Ipomæa Jalapa (*Nuttall*). *U. S.* The dried tubercules of Exogonium Purga. *Br.*

Jalap, *Fr.;* Jalappenwurzel, *Germ.;* Sciarappa, *Ital.;* Jalapa, *Span.*

The precise botanical origin of jalap remained long unknown. It was at first ascribed by Linnæus to a Mirabilis, and afterwards to a new species of Convolvulus, to which he gave the name of *C. Jalapa.* The correctness of the latter reference was generally admitted; and, as the *Ipomæa macrorrhiza* of Michaux, growing in Florida and Georgia, was believed to be identical with the C. Jalapa of Linn., it was thought that this valuable drug, which had been obtained exclusively from Mexico, might be collected within the limits of the United States. But the error of this opinion was soon demonstrated; and it is now an admitted fact, that jalap is the product of a plant first made known to the scientific world by Dr. John R. Coxe, of Philadelphia, and described by Mr. Nuttall under the name of *Ipomæa Jalapa.* When this Dispensatory was first published, opinion in relation to the botanical history of the drug was unsettled, and it was deemed proper to enter at some length into the consideration of the subject; but the subsequent general admission of the views then advocated renders an equal degree of minuteness now unnecessary. It is sufficient to state that Dr. Coxe received living roots of jalap from Mexico in 1827, and succeeded in producing a perfect flowering plant, of which a description, by Mr. Nuttall, was published in the *Am. Journ. of Med. Sci.* for January, 1830; that the same plant was afterwards cultivated in France and Germany from roots transmitted to those countries from Mexico; and that one of the authors of this work has produced, from roots obtained in the vicinity of Xalapa, and sent to him by the late Dr. Marmaduke Burrough, then United States consul at Vera Cruz, luxuriant plants, which he was enabled to compare with others descended from the plant of Dr. Coxe, and found to be identical with them. In the United States and British Pharmacopœias this origin of jalap is now recognised. J. H. Balfour (*Curtis's Bot. Mag.*, Feb. [illegible]) maintains that the plant belongs to the genus *Exogo-*

nium of Choisy, as defined in De Candolle's Prodromus, being distinguished from Ipomæa by its exserted stamens; and this view has been taken by the framers of the British Pharmacopœia.

Ipomæa. *Sex. Syst.* Pentandria Monogynia. — *Nat. Ord.* Convolvulaceæ.

Gen Ch. Sepals five. *Corolla* campanulate. *Stamens* included. *Style* one. *Stigma* two-lobed; the lobes capitate. *Ovary* two-celled; cells two-seeded. *Capsule* two-celled. *Lindley.*

Ipomæa Jalapa. Nuttall. *Am. Journ. of Med. Sciences,* v. 300; Carson, *Illust. of Med. Bot.* ii. 13, pl. 61. — *Ipomæa Purga.* Hayne, *Darstel. und Beschreib.* &c. xii. 33 and 34; Lindley, *Flor. Med.* 396. — *Exogonium Purga.* Balfour, *Curtis's Bot. Mag.*, 3d ser., vol. iii. tab. 4280. The root of this plant is a roundish somewhat pear-shaped tuber, externally blackish, internally white, with long fibres proceeding from its lower part, as well as from the upper rootstalks. A tuber produced by Dr. Coxe was, in its third year, between two and three inches in diameter. The stem is round, smooth, much disposed to twist, and rises to a considerable height upon neighbouring objects, about which it twines. The leaves are heart-shaped, entire, smooth, pointed, deeply sinuated at the base, prominently veined on their under surface, and supported upon long footstalks. The lower leaves are nearly hastate, or with diverging angular points. The flowers, which are large and of a lilac-purple colour, stand upon peduncles about as long as the petioles. Each peduncle supports two, or, more rarely, three flowers. The calyx is without bractes, five-leaved, obtuse, with two of the divisions external. The corolla is funnel-form. The stamens are five in number, with oblong, white, somewhat exserted anthers. The stigma is simple and capitate. The above description is taken from that of Mr. Nuttall, published in Dr. Coxe's paper in the *American Journal of the Med. Sciences.*

The jalap-plant is a native of Mexico, and derived its name from the city of Xalapa, in the state of Vera Cruz, in the neighbourhood of which it grows, at the height of about 6000 feet above the ocean. The drug is brought from the port of Vera Cruz in bags, containing usually between 100 and 200 pounds.

Properties. The tuber comes either whole, or divided longitudinally into two parts, or in transverse circular slices. The entire tubers are irregularly roundish, or ovate and pointed, or pear-shaped, usually much smaller than the fist, and marked with circular or vertical incisions, made to facilitate their drying. The root is preferred in this state, as it is less apt to be defective, and is more easily distinguished from the adulterations than when sliced. A much larger proportion comes entire than formerly, indicating a greater scarcity of the older roots, which it is necessary to slice in order to dry them properly. The tuber is heavy, compact, hard, brittle, with a shining undulated fracture, exhibiting numerous resinous points, distinctly visible with the microscope. It is externally brown and wrinkled, internally of a grayish colour, diversified by concentric darker circles, in which the matter is denser and harder than in the intervening spaces. Jalap is always kept in the shops in the state of powder, which is of a yellowish-gray colour, and when inhaled irritates the nostrils and throat, and provokes sneezing and coughing. The odour of the root, when cut or broken, is heavy, sweetish, and rather nauseous; the taste is sweetish, somewhat acrid, and disagreeable. It yields its active properties partly to water, partly to alcohol, and completely to diluted alcohol. M. Cadet de Gassicourt obtained from 500 parts of jalap, 24 of water, 50 of resin, 220 of gummy extract, 12·5 of fecula, 12·5 of albumen, 145 of lignin, 16·3 of saline matters, 2·7 of silica, with a loss of 17 parts. Buchner and Herberger supposed that they had discovered a basic substance, which they called *jalapin.* G. A. Kayser found that the resin of jalap consists of two portions, one of which, amounting to seven parts out of ten, is hard and insoluble in ether, the other is soft and soluble in that menstruum. The hard resin he named *rhodeoretin,* and found to be identical with the jalapin of Buchner and Herberger. By reaction with the alkalies it is converted into an acid, called *rhodeoretinic acid.* Rhodeoretin is slightly soluble in water, freely so in alcohol, and insoluble in ether, chloroform, or benzole;

and the alcoholic solution is precipitated both by ether and water. It is dissolved by solutions of the alkalies, more quickly if heated, and is not precipitated by acids, having become soluble by conversion into the acid above referred to. It purges violently in the dose of three or four grains, and is supposed to be the active principle of jalap. Mayer has confirmed and extended the observations of Kayser. The formula of rhodeoretin, according to the latter chemist, is $C_{42}H_{35}O_{20}$, according to the former, $C_{72}H_{60}O_{36}$. (See *Chem. Gaz.*, iii. 15, and xi. 21.) Rhodeoretin and rhodeoretinic acid are both glucosides, being convertible by the action of acids into glucose and a peculiar substance named *rhodeoretinol.* (*Pelouze* and *Fremy.*) The proportion of resin to the other ingredients of the root varies considerably in different specimens. According to Gerber, the root contains 7·8 per cent. of hard resin, 3·2 of soft resin, 17·9 of extractive, 14·5 of gummy extract, 8·2 of a colouring substance which becomes red under the influence of the alkaline carbonates, 1·9 of uncrystallizable sugar, 15·6 of gum mixed with some saline matters, 3·2 of bassorin, 3·9 of albumen, 6·0 of starch, 8·2 of lignin, with some water, and various salts. For the method of obtaining the resin of jalap pure, see *Resina Jalapæ.**

Jalap is apt to be attacked by worms, which, however, are said to devour the amylaceous or softer parts, and to leave the resin; so that the worm-eaten drug is more powerfully purgative than that which is sound. Thus, out of 397 parts of the former, M. Henry obtained 72 parts of resin, while from an equal quantity of the latter he procured only 48 parts. Hence worm eaten jalap should be employed for obtaining the resin, but should not be pulverized, as it would afford a powder of more than the proper strength. The drug is also liable to various adulterations, or fraudulent substitutions, which, however, can usually be detected without difficulty. Those which have attracted particular attention are mentioned in the note below.† Jalap should be rejected when it is light,

* True jalap varies much in the proportion of resin, and consequently in purgative power. Dr. E. R. Squibb has found the proportion to vary from 11 per cent. in the lower grades up to 16·25 per cent. in the best (*Am. Journ. of Pharm.*, Jan. 1868, p. 65); but others have obtained a considerably greater proportion than the largest mentioned; and Mr. Charles Umney states that, in a fine selected specimen, he had found 21·5 per cent. (*Pharm. Journ. and Trans*, Dec. 1867, p. 282.)

† *Adulterations, Substitutions, &c.* The original source of jalap seems to be failing, while, from increased population, the demand in the general market has been increasing; so that the supply of the genuine drug is insufficient; and other substances, more or less allied to jalap in appearance or medicinal properties, have been introduced to supply the deficiency. The consequence is that great care is requisite to avoid deception; and there is reason to believe that the quality of the medicine, as found in the shops, is deteriorating from the fraudulent admixture of these inferior substances with the genuine drug in pulverization. The only sure remedy for this great evil is increased production; and this can be accomplished only by the cultivation of the plant, either in its native Mexico, or in other countries adapted to its growth. From some little experience with the propagation of the true jalap plant, the author has no doubt that it would grow well in some of our Southern States, especially in the interior high grounds. It is said that some isolated attempts have been made by the native Mexicans to cultivate the plant, and that the products of this cultivation have reached the European market. In a communication from Dr. G. Naphegyi, in the *Med. and Surg. Reporter* (April 18, 1868, p. 342), it is stated that some of the European gardeners, in the vicinity of the city of Mexico, are making its cultivation a subject of speculation; and an order was issued by the late Emperor Maximilian, to the Prefects of the province of Jalapa, recommending its cultivation. There is, therefore, some reason to hope that the supply of this valuable medicine may be augmented.

Among the inferior kinds of jalap are specimens of the genuine root which appear to have been partially exhausted in their aggregate state before pulverization. From a pound of this kind Dr. Squibb obtained only 1·8 per cent. of resin. The rootlets of the tubers are sometimes mixed in large proportion with the tubers themselves. The same chemist found in a lot of this kind 2·2 per cent. of resin. (*Am. Journ. of Pharm.*, Jan 1868, pp. 65-6.)

Jalap of Tampico. Considerable quantities of a tuberous root have recently been imported into Europe, and probably also into this country, under the name of Tampico jalap; being distinguished by the name of the port from which it comes from the true jalap, which is brought exclusively from Vera Cruz. Its botanical source is unknown, but, from its resem-

of a whitish colour internally, of a dull fracture, spongy, or friable. Powders of calomel and jalap, taken on long voyages to southern climates, are said,

blance to the true jalap, it is probably the product of a plant belonging to the same family of Convolvulaceæ. According to M. Ambrose Andouard, it is the same as the false jalap described by M. Guibourt as the *larger digitate jalap* (*jalap digité majeur*). It is inferior to the true jalap, as its resin is invariably in smaller proportion, and chemically differs from that of the true jalap; as it is almost wholly soluble in ether, while the genuine yields only 12 per cent. to that menstruum. The odour of the Tampico jalap is said closely to resemble that of peat, and is very adhesive, being perceptible even in the extract and resin. This odour has been conjecturally ascribed to the drying of the tubers by a peat fire. The finest specimens of this drug yield 14 per cent. of resin, while inferior kinds give only 5 per cent. The resin is said to be purgative. The facts in this note in relation to Tampico jalap have been derived from a paper by Mr. Charles Umney, in the *Pharm. Journ. and Trans.* (Decemb. 1867, p. 282); as the author has been unable to procure a specimen of the drug on the genuineness of which he could rely. (*Note to the thirteenth edition.*)

Mechoacan. Jalap is said to be sometimes adulterated with *bryony root;* but no instance of the kind has come under our notice; and the two drugs are so widely different that the fraud would be instantly detected. (See *Bryony*, in *Part Third.*) It is probable, however, that the adulteration which has been considered as bryony root is the *mechoacan*, which in Europe is sometimes called American bryony, and was formerly erroneously supposed to be derived from a species of Bryonia. Mechoacan is a product of Mexico, which was taken to Europe even before the introduction of jalap. The plant producing it has been conjectured to be *Ipomæa macrorrhiza* of Michaux, which is believed to grow in Mexico near Vera Cruz, as well as in our Southern States, and the root of which is said to weigh, when of full size, from fifty to sixty pounds, and, according to Dr. Baldwin, has little or no purgative power. But this origin is quite uncertain; and Guibourt states, in one of his most recent communications to the journals, that what is sold in Europe under the name of mechoacan is certainly the product of *Asclepias Contrayerva* of the Mexican flora. (*Journ. de Pharm. et de Chim.*, 4e sér., iv. 98, A. D. 1866.) Mechoacan is in circular slices, or fragments of various shapes, white and farinaceous within, and, as found in the European markets, generally destitute of bark, of which, however, portions of a yellowish colour sometimes continue to adhere. The larger slices are sometimes marked with faint concentric striæ; and upon the exterior surface are brown spots and ligneous points, left by the radicles after removal. (*Guibourt.*) Though tasteless when first taken into the mouth, it becomes after a time slightly acrid. It is very feebly purgative. We have seen flat circular pieces of root, mixed with jalap, altogether answering this description, except that the cortical portion still remained, between which and the starchy parenchyma there was an evident line of division.

Male Jalap. Fusiform Jalap. Jalap Stalks A drug, formerly known in our markets as spurious jalap, sometimes comes mingled with the genuine, and has been imported, unmixed, in mistake for that root. It is the same with that referred to by French writers as the product of a plant denominated *male jalap* in Mexico, and named by M. Ledanois *Convolvulus Orizabensis*, from the city of Orizaba, in the neighbourhood of which it grows abundantly. In the shops of Paris the drug is called *light jalap*, and, in Guibourt's *Histoire des Drogues*, is described under the title of *fusiform jalap.* A description of it was first published in this country by Mr. D. B. Smith, in a paper upon Ipomæa Jalapa, in the *Am. Journ. of Pharm.* (ii. 22). For an account of the plant, the reader is referred to the same journal (x. 224). The recent root is large, spindle-shaped, sometimes twenty inches in length, branched at its lower extremity, yellow on its outer surface, and white and milky within. The drug, as described by Guibourt, is in circular pieces, two or three inches in diameter, or in longer and more slender sections. As we have seen it, the shape of the pieces is often such as to indicate that the root was sliced transversely, and each circular slice divided vertically into quarters. The horizontal cut surface is dark from exposure, unequal from the greater shrinking in desiccation of some parts than others, and presents the extremities of numerous fibres, which are often concentrically arranged, and run in the longitudinal direction of the root. Internally the colour is grayish, and the texture, though much less compact than that of jalap, is sometimes almost ligneous. The taste is at first slight, but after a time becomes somewhat acrid and nauseous. The root, analyzed by M. Ledanois, yielded, in 1000 parts, 80 of resin, 256 of gummy extract, 32 of fecula, 24 of albumen, and 580 of lignin. It has cathartic properties similar to those of the true jalap, but feebler, requiring to be given in a dose of from thirty to sixty grains in order to operate effectively. The proportion of resin, which in both is the purgative principle, is considerably less in the male jalap; while that of lignin, which is wholly inert, is about double. (*Journ. de Pharm.*, xxiv. 166.) This resin, according to G. A. Kayser, differs from jalap resin in consisting of only one principle, which is entirely soluble in ether. But both resins are distinguished from all others by being gradually dissolved in concentrated sulphuric acid, and deposited again

when brought back, to have become consolidated, and so far chemically altered as plainly to exhibit globules of mercury. This change is ascribed by Schacht and Wackenroder to a fungous growth. (*Arch. der Pharm.*, xxxix. 239.) The best criterion of good quality in jalap is the proportion of its resinous constituent; and all specimens intended for use in the powdered form, or in any liquid preparation, should be rejected if it contain less than 11 or 12 per cent. of resin.

Medical Properties and Uses. Jalap is an active cathartic, operating briskly and sometimes painfully upon the bowels, and producing copious watery stools. The aqueous extract purges moderately, without much griping, and is said to increase the flow of urine. The portion not taken up by water gripes severely. The watery extract obtained from jalap, previously exhausted by rectified spirit,

after some hours in a soft state. (*Chem. Gaz.*, no. 53; from Liebig's *Annalen.*) The resin of C. Orizabensis, which has been unfortunately named *jalapin* by Mayer, is, according to that chemist, changed by boiling with baryta-water into an acid called *jalapic* acid; and both jalapin and jalapic acid are glucosides, being resolved by boiling dilute acid into glucose, and a peculiar substance which he designates as *jalapinol.* (See *Journ. de Pharm.*, 3e sér., xxix. 123.)

Rose-scented Jalap. Overgrown Jalap. A false jalap was some years since brought into the United States, different from anything before seen in our market. It was said to have been imported from Mexico into New York in considerable quantities, and was offered for sale under the name of *overgrown jalap.* A specimen, brought to Philadelphia, and examined by a Committee of the College of Pharmacy, presented the following characters. It was in light, entire or vertically sliced tubers, of different form and magnitude, spindle-shaped, ovate, and kidney-form, some as much as six inches long and three thick, others much smaller, externally somewhat wrinkled, with broad flattish light-brown ridges, and shallow darker furrows, internally grayish-white, with distant darker concentric circles, sometimes uniformly amylaceous, of a dull rough fracture, a loose texture, a slight, peculiar, and sweetish odour, and a feeble jalap-like taste. The powder was of a light-gray colour, and did not irritate the nostrils or throat during pulverization. The root differed from mechoacan by the absence of the marks of rootlets, and from male jalap by the want of a fibrous structure. It yielded by analysis, in 100 parts, 3 of a soft and 4 of a hard and brittle resin, 17 of gummy extractive, 28 of starch and inulin, 10 of gum and albumen, 23·2 of lignin, and 14·8 of saccharine matter and salts of lime, including loss. In doses of from fifteen to twenty grains it produced no effect on the system. A similar root was described by Guibourt by the name of *rose-scented jalap.* It was taken to France from Mexico, mixed with genuine jalap. It proved equally inefficacious as a purgative, and probably had the same origin. This spurious drug is probably the product of a Convolvulus or Ipomæa. See report by Messrs. Ellis, Duhamel, and Ecky, in the *Am. Journ. of Pharm.* (xiv. 289).

Two varieties of false jalap, imported into New York, are described by Mr. John H. Currie in the *N. Y. Journ. of Pharm.* for Jan. 1852. The first corresponds with the root above described as that of Convolvulus Orizabensis, or *male jalap*, both in appearance and in the character of its resinous ingredient. The second is a tuberous root, resembling in shape, colour, and size, the butternut, or fruit of Juglans cinerea, being black or nearly so externally, dull over most of the surface but glossy in spots, with deep longitudinal incisions, internally yellow or yellowish-white, with a horny fracture, and upon the transversely cut surface marked with sparse dots, as if from delicate fibres. It contains no resin, and appears to be inert.

In the numbers of the *Journal de Pharmacie*, &c. for Dec. 1863 (p. 477), and for March, 1864 (p. 212), three other tubers are described by M. Guibourt, which have been offered in the market for jalap; one named *false jalap of New Orleans*, because imported into France from that city, the second *digitate jalap* (*jalap digité*) from the arrangement of its component tubers, and the third *radiated false-jalap* (*faux-jalap rayonné*) from the stellate appearance of the cut surface. Our space will not permit a particular description of these substances, which is the less important, as they are not likely to be mistaken for the true jalap by one at all acquainted with the characters of the latter; and, besides, do not appear in themselves to possess any valuable properties. We must, therefore, content ourselves with referring to the original papers. (*Notes to former editions.*)

Another false jalap, some tubers of which were exhibited to Prof. Procter by Mexicans, who stated that they were produced on grounds in Mexico belonging to them, is described by him in the *Am. Journ. of Pharm.* (Sept. 1868, p. 389), to which the reader is referred for a particular account of it. Though differing in shape and interior structure from genuine jalap, they had precisely the odour of that product, and a similar wrinkled appearance and mottled brown colour externally, and were probably derived from a plant either of the same genus as jalap or one closely related to it. (*Note to the thirteenth edition.*)

is said to have no cathartic effect, but to operate powerfully by urine. (*Duncan.*) The alcoholic extract, usually called resin of jalap, purges actively, and often produces severe griping. From these facts, it would appear that the virtues of this cathartic do not depend exclusively upon any one principle. Experiments, however, by Mr. John C. Long, of Philadelphia, seem to show that the gummy extract, which he took in the quantity of a drachm without any effect, is inert; while the soft resin, or that soluble in ether, which was thought to have but feeble power, if any, acted powerfully as a hydragogue cathartic, in the dose of three grains. (*Am. Journ. of Pharm.*, Nov. 1861, p. 489.) Jalap was introduced into Europe in the latter part of the sixteenth, or beginning of the seventeenth century, and now ranks among the purgative medicines most extensively employed. It is applicable to most cases in which an active cathartic is required, and from its hydragogue powers is especially adapted to the treatment of dropsy. It is generally given in connection with other medicines, which assist or qualify its operation. In dropsical complaints it is usually combined with bitartrate of potassa; and the same mixture is much employed in the treatment of the hip disease, and scrofulous affections of other joints. With calomel it forms a cathartic compound, which has long been highly popular, in the United States, in bilious fever and other complaints attended with congestion of the liver or portal circle. In overdoses it may produce dangerous hypercatharsis. It is said to purge when applied to a wound.

The dose of jalap in powder is from fifteen to thirty grains; of the resin, or alcoholic extract, from four to eight grains; of the extract of the U. S. and Br. Pharmacopœias, from ten to twenty grains. The latter extract is preferable to the alcoholic, as it more completely represents jalap itself. The dose of calomel and jalap is ten grains of each; of bitartrate of potassa and jalap, two drachms of the former and ten or fifteen grains of the latter.

Several products of *Juglans regia*, or common *European walnut*, are used medicinally in Europe. The hull of the fruit has been employed as a vermifuge from the times of Hippocrates, and has been recommended in syphilis and old ulcers. The expressed oil of the fruit has been deemed efficacious against the tape-worm, and is also used as a laxative injection. The *leaves*, long occasionally employed for various purposes both in regular and domestic practice, have been found by Professor Négrier, of Angers, in the highest degree efficacious in scrofula. He gave to children a teacupful of a pretty strong infusion, or six grains of the aqueous extract, or an equivalent dose of a syrup prepared from the extract, two, three, or four times a day; and at the same time applied a strong decoction to the ulcers, and as a collyrium when the eyes were diseased. No injury ever resulted from a long-continued use of the remedy. It appears to act as a moderately aromatic bitter and astringent. (*Arch. Gen.*, 3e série, x. 399 and xi. 41.) They are said also to have proved useful as a topical application in malignant pustule. (*Ibid.*, 5e sér., x. 609.) The leaves of our *J. nigra*, or common *black walnut*, and those of *J. cinerea*, the only officinal species, probably possess the same properties.

Juglans cinerea. Willd. *Sp. Plant.* iv. 456; Bigelow, *Am. Med. Bot.* ii. 115; Carson, *Illust. of Med. Bot.* ii. 42, pl. 86. — *J. cathartica.* Michaux, *N. Am.*

Sylva, i 160. This is an indigenous forest tree, known in different sections of the country by the names of *butternut*, *oilnut*, and *white walnut*. In favourable situations it attains a great size, rising sometimes fifty feet, with a trunk three or four feet in diameter at the distance of five feet from the root. The stem divides, at a short distance from the ground, into numerous nearly horizontal branches, which spread widely, and form a large tufted head. The young branches are smooth and of a grayish colour, which has given origin to the specific name of the plant. The leaves are very long, and consist of seven or eight pairs of sessile leaflets, and a single petiolate leaflet at the end. These are two or three inches in length, oblong-lanceolate, rounded at the base, acuminate, finely serrate, and somewhat downy. The male and female flowers are distinct upon the same tree. The former are in large aments, four or five inches long, hanging down from the sides of the shoots of the preceding year's growth, near their extremity. The fertile flowers are at the end of the shoots of the same spring. The germ is surmounted by two large feathery, rose-coloured stigmas. The fruit is sometimes single, suspended by a thin pliable peduncle; sometimes several are attached to the sides and extremity of the same peduncle. The drupe is oblong-oval, with a terminal projection, hairy, viscid, green in the immature state, but brown when ripe. It contains a hard, dark, oblong, pointed nut, with a rough, deeply and irregularly furrowed surface. The kernel is thick, oily, and pleasant to the taste.

The butternut grows in Upper and Lower Canada, and throughout the whole northern, eastern, and western sections of the old United States. In the Middle States, the flowers appear in May, and the fruit ripens in September. The tree, if pierced immediately before the leaves unfold, yields a richly saccharine juice, from which sugar may be obtained, nearly if not quite equal to that from the sugar maple. The wood, though neither strong nor compact, is useful for some purposes on account of its durability, and exemption from the attacks of worms. The fruit, when half-grown, is sometimes made into pickles, and, when ripe, affords in its kernel a grateful article of food. The bark is used for dyeing wool a dark-brown colour, though inferior for this purpose to that of the black walnut. It is said, when applied to the skin, to be rubefacient. The inner bark is the medicinal portion, and that of the root, being considered most efficient, is directed by the Pharmacopœia. It should be collected in May or June.

On the living tree, the inner bark, when first uncovered, is of a pure white, which becomes immediately on exposure a fine lemon colour, and ultimately changes to deep brown. It has a fibrous texture, a feeble odour, and a peculiar, bitter, somewhat acrid taste. Its medical virtues are extracted by boiling water. Dr. Bigelow could detect no resin in the bark; and the presence of tannin was not evinced by the test of gelatin, though a brownish-black colour was produced by sulphate of iron.

Medical Properties and Uses. Butternut is a mild cathartic, operating without pain or irritation, and resembling rhubarb in the property of evacuating without debilitating the alimentary canal. It was much employed, during our revolutionary war, by Dr. Rush and other physicians attached to the army. It is especially applicable to cases of habitual costiveness and other bowel affections, particularly dysentery, in which it has acquired considerable reputation. In connection with calomel it has sometimes been used in our intermittent and remittent fevers, and other complaints attended with congestion of the abdominal viscera. It is given in the form of decoction or extract, never in substance. The extract is officinal, and is almost always preferred. The dose of it is from twenty to thirty grains as a purge, from five to ten grains as a laxative.

FEMALE. *Calyx* three-parted. *Petals* three. *Styles* three. *Berry* three-seeded, irregular, with the three tubercles of the calyx. *Willd.*

Juniperus communis. Willd. *Sp. Plant.* iv. 853; Woodv. *Med. Bot.* p. 13, t. 6. This is an erect evergreen shrub, usually small, but sometimes twelve or fifteen feet high, with numerous very close branches. The leaves are narrow, longer than the fruit, entire, sharply pointed, channeled, of a deep-green colour, somewhat glaucous on their upper surface, spreading, and attached to the stem or branches in threes, in a verticillate manner. The flowers are dicœcious, and disposed in small, ovate, axillary, sessile, solitary aments. The fruit is formed of the fleshy coalescing scales of the ament, and contains three angular seeds.

The common juniper is a native of Europe; but has been introduced into this country, in some parts of which it has become naturalized. It is not uncommon in the neighbourhood of Philadelphia The plant described in Bigelow's American Medical Botany, under the title of *J. communis*, and very common in certain parts of New England, deserves, perhaps, to be considered a distinct species. It is a trailing shrub, seldom more than two or three feet high, spreading in all directions, throwing out roots from its branches, and forming beds which are often many rods in circumference. The name of *J. depressa* has been proposed for it. The common juniper flowers in May, but does not ripen its fruit till late in the following year. All parts of the plant contain a volatile oil, which imparts to them a peculiar flavour. The wood has a slight aromatic odour, and was formerly used for fumigation. A terebinthinate juice exudes from the tree and hardens on the bark. This has been erroneously considered as identical with *sandarach.* The peasantry in the south of France prepare a sort of tar, which they call "*huile de cade,*" from the interior reddish wood of the trunk and branches, by a distillation *per descensum.* (See *Oil of Cade,* in *Part III.*) The fruit and tops of juniper are the only officinal parts.

The berries, as the fruit is commonly called, are sometimes collected in this country, and parcels are occasionally brought to the Philadelphia market from New Jersey. But, though equal to the European in appearance, they are inferior in strength, and are not much used. The best come from the south of Europe, particularly from Trieste and the Italian ports. They are globular, more or less shrivelled; about as large as a pea; marked with three furrows at the summit, and with tubercles from the persistent calyx at the base; and covered with a glaucous bloom, beneath which they are of a shining blackish-purple colour. They contain a brownish-yellow pulp, and three angular seeds. They have an agreeable somewhat aromatic odour, and a sweetish, warm, bitterish, slightly terebinthinate taste. These properties, as well as their medical virtues, they owe chiefly to a volatile oil. (See *Oleum Juniperi.*) The other ingredients, according to Trommsdorff, are resin, sugar, gum, wax, lignin, water, and various saline substances. The proportion of these ingredients varies according to the greater or less maturity of the berries. The volatile oil is most abundant in those which have attained their full growth and are still green, or in those which are on the point of ripening. In the latter, Trommsdorff found one per cent. of the oil. In those perfectly ripe it has been partly changed into resin, and in those quite black, completely so.* The berries impart their virtues to water and alcohol. They are very largely consumed in the preparation of gin.

* Franz Steer of Cashau, in a more recent analysis, found the sugar to be glucose, and, besides the principles discovered by Trommsdorff, obtained pectin, malic acid, and a peculiar resin-like substance, which he names *juniperin.* This is black, with a yellow

The tops of juniper were formerly directed by the *Edinburgh* and *Dublin Colleges*. Their odour is balsamic, their taste resinous and bitterish, and they possess similar virtues with the berries.

Medical Properties and Uses. Juniper berries are gently stimulant and diuretic, imparting to the urine the smell of violets, and producing occasionally, when largely taken, disagreeable irritation in the urinary passages. They are chiefly used as an adjuvant to more powerful diuretics in dropsical complaints; but have been recommended also in scorbutic and cutaneous diseases, catarrh of the bladder, and atonic conditions of the alimentary canal and uterus. They may be given in substance, triturated with sugar, in the dose of one or two drachms three or four times a day. But the infusion is more convenient. It is prepared by macerating an ounce of the bruised berries in a pint of boiling water, the whole of which may be taken in the course of twenty-four hours. Extracts are prepared from the berries, both bruised and unbruised, and given in the dose of one or two drachms; but, in consequence of the evaporation of the essential oil, they are probably not stronger than the berries in substance.

JUNIPERUS VIRGINIANA. *U. S. Secondary.*

Red Cedar.

The tops of Juniperus Virginiana. *U. S.*

JUNIPERUS. See JUNIPERUS.

Juniperus Virginiana. Willd. *Sp. Plant.* iv. 853; Bigelow, *Am. Med. Bot.* iii. 49; Michaux, *N. Am. Sylv.* iii. 221. This species of Juniper, commonly called *red cedar*, is an evergreen tree of slow growth, seldom very large, though sometimes rising forty or fifty feet, with a stem more than a foot in diameter. It has numerous very close branches, which, in the young tree, spread out horizontally near the ground; but, as the tree advances, the lower branches slowly decay, leaving the trunk irregular with knots and crevices. The leaves are very small, fleshy, ovate, concave, pointed, glandular on their outer surface, ternate or in pairs, and closely imbricated. Those of the young shoots are often much longer and spreading. The leaves closely invest the extreme twigs, increasing with their growth, till ultimately lost in the encroachments of the bark. "The barren flowers are in oblong aments, formed by peltate scales with the anthers concealed within them. The fertile flowers have a proper perianth, which coalesces with the germ, and forms a small, roundish berry, with two or three seeds, covered on its outer surface with a bright blue powder." (*Bigelow.*)

The red cedar grows in all latitudes of the United States, from Burlington, in Vermont, to the Gulf of Mexico; but it is most abundant and vigorous in the southern section. The interior wood is of a reddish colour, and highly valuable on account of its great durability. Small excrescences, which are sometimes found on the branches of the tree, are popularly used as an anthelmintic, under the name of *cedar apples*, in the dose of from ten to twenty grains three times a day. The tops or leaves only are officinal.

They have a peculiar not unpleasant odour, and a strong, bitterish, somewhat pungent taste. These properties reside chiefly in a volatile oil, and are readily imparted to alcohol. The leaves, analyzed by Mr. Wm. J. Jenks, were found to contain volatile oil, gum, tannic acid, albumen, bitter extractive, resin, chloro-

tint in thin layers by transmitted light, brittle, easily pulverizable, tasteless, insoluble in water and ether, but soluble in alcohol, and without acid or alkaline reaction. A singular property is that, when rubbed with a little water, it changes into a yellow powder, which is perfectly soluble in 66 parts of water, and has in solution an unpleasant bitter taste. It is obtained by distilling a tincture of the berries until nearly all the alcohol has passed over, pouring the residue while hot into a vessel, in which it deposits a gum-resin on cooling, decanting the clear liquid and reducing it with a gentle heat to a small volume, and allowing it to stand. A yellow powder separates, resembling powdered rhubarb, which disappears by further evaporation, and is followed by resinous drops, which, separated and washed, constitute the substance in question. (*Chem. Cent. Blatt*, Dec. 31, 1856, p. 951.)

phyll, fixed oil, lime, and lignin. (*Am. Journ. of Pharm.*, xiv. 235) They bear a close resemblance to the leaves of *Juniperus Sabina*, from which they can be certainly distinguished only by the difference of odour.

Medical Properties and Uses. The resemblance of red cedar to savine is said also to extend to their medical properties; the former being considered, like the latter, stimulant, emmenagogue, diuretic, and, under certain circumstances, diaphoretic. It is, however, much less energetic; and, though advantage may, as has been asserted, have accrued from it in amenorrhœa, chronic rheumatism, and dropsy, it has not acquired the confidence of the profession generally. Externally applied it acts as an irritant; and an ointment, prepared by boiling the fresh leaves for a short time in twice their weight of lard, with the addition of a little wax, is employed as a substitute for savine cerate in maintaining a purulent discharge from blistered surfaces. Sometimes the dried leaves in powder are mixed with six times their weight of resin cerate, and used for a similar purpose. But neither of these preparations is as effectual as the analogous preparation of savine.* W.

KINO. *U.S. Br.*

Kino.

The inspissated juice of Pterocarpus Marsupium, and of other plants. *U. S.* The inspissated juice obtained from incisions made in the trunk of Pterocarpus Marsupium. *Br.*

Kino, *Fr., Germ., Ital.;* Quino, *Span.*

The term kino was originally applied to a vegetable extract or inspissated juice, taken to London from the western coast of Africa, and introduced to the notice of the profession by Dr. Fothergill. Vegetable products obtained from various other parts of the world, resembling kino in appearance and properties, afterwards received the same name; and much confusion and uncertainty have existed, and in some degree still exist, in relation to the botanical and commercial history of the drug. We shall first give an account of the general properties of the medicines denominated kino, and then treat of the several varieties.

General Properties. Kino, as found in the shops, is usually in small, irregular, angular, shining fragments, seldom so large as a pea, of a dark reddish-brown or blackish colour, very brittle, easily pulverizable, and affording a reddish powder, much lighter coloured than the drug in its aggregate state. If in large masses, it may be reduced without difficulty into these minute fragments. It is without odour, and has a bitterish, highly astringent taste, with a somewhat sweetish after-taste. It burns with little flame, and does not soften with heat. It imparts its virtues and a deep-red colour to water and alcohol. Cold water forms with it a clear infusion. Boiling water dissolves it more largely; and the saturated decoction becomes turbid on cooling, and deposits a reddish sediment. The tincture is not disturbed by water. When long kept it often gelatinizes, and loses its astringency. (See *Tinctura Kino.*) Kino has been supposed to consist chiefly of a modification of tannic acid or tannin, with extractive, gum, and sometimes probably a little resin; but we need a careful analysis of the different well-ascertained varieties. The aqueous solution is precipitated by gelatin, the soluble salts of iron, silver, lead, and antimony, bichloride of mercury,

* In the *Boston Medical and Surgical Journal* (xl. 469), several cases of poisoning are recorded by Dr. S. C. Watt, of Gouverneur, New York, resulting from the use of "*cedar oil*," which we presume to be the volatile oil procured by distillation from the red cedar, though no information on that point is given. It appears that this oil has the reputation of producing abortion, and was taken, in three of the cases described, with a view to that effect. In one instance a fluidrachm was taken, in another a fluidounce, and in both of these cases recovery took place. Two of the cases were fatal. The symptoms were burning in the stomach, sometimes vomiting, violent convulsions, coma, and a very slow pulse. The operation of the poison was mainly on the brain. No abortive effect was experienced in either case. The stomach, on examination after death, showed marks of inflammation, but not violent. (*Note to the ninth edition.*)

and sulphuric, nitric, and muriatic acids. The precipitate with iron is of an olive or greenish-black colour. The alkalies favour the solubility of kino in water, but essentially change its nature, and destroy its astringency.

1. *East India Kino.* This is the variety at present probably most used, and most highly esteemed, and the only one recognised by the British Pharmacopœia. Its origin was long unknown. It is now ascertained, through the united researches of Drs. Pereira, Royle, Wight, and others, to be the product of *Pterocarpus Marsupium*, a lofty tree, growing upon the mountains of the Malabar coast of Hindostan. Kino is the juice of the tree, extracted through longitudinal incisions in the bark, and afterwards dried in the sun. Upon drying it breaks into small fragments, and is put into wooden boxes for exportation. It is collected near Tellicherry, and exported from Bombay. It is sometimes imported into this country directly from the East Indies, but more commonly from London. From a communication in the Journal of the Asiatic Society of Bengal, by the Rev. F. Mason, it appears that kino is also collected in the Tenasserim provinces, in Further India, and has been exported from Maulmain to Europe. It is produced by a tree called *Pa-douck*, which is supposed to be a species of Pterocarpus; but its precise character was not certainly known. (*Am. Journ. of Pharm.*, xxi. 134.) Dr. Christison has subsequently recognised, in a description of this tree furnished to him by Mr. Begbie, of Maulmain, the precise characters of Pterocarpus Marsupium; so that this kino has the same origin with that from Malabar.

East India kino is in small, angular, glistening fragments, of a uniform consistence, appearing as if formed by the breaking down of larger masses. The larger fragments are opaque and nearly black; but minute splinters are sometimes translucent, and of a deep garnet redness when viewed by transmitted light. This variety of kino is very brittle, readily breaking between the fingers, and easily pulverized, affording a dark-reddish powder, a portion of which, resulting from the mutual attrition of the fragments, is often found interspersed among them. When chewed, it softens in the mouth, adheres somewhat to the teeth, and tinges the saliva of a blood-red colour. In odour, taste, and chemical relations, it corresponds with the account already given of kino in general. According to Vauquelin, it contains 75 per cent. of tannin and peculiar extractive, 24 of red gum, and 1 of insoluble matter. But new views have been advanced as to its composition. When kino is boiled in water, the decoction deposits on cooling a bright-red substance; and a similar deposition takes place when a cold filtered aqueous solution is long exposed with a broad surface to the air. Dr. Gerling considers this deposit as the result of the combination of oxygen with kino-tannic acid, and calls it *kino-red.* (*Chem. Gaz.*, ix. 260; from Liebig's *Annalen.*) Hennig, who has examined East India kino with some care, considers this kino-red as a colouring matter in intimate combination with the tannic acid, which he is disposed to think identical in its pure state with the tannic acid of galls; and he extends the same views to the other forms of this astringent principle which give greenish precipitates with the salts of sesquioxide of iron, and which are generally believed to be somewhat different as they occur in different plants. Finding this red colouring matter to possess acid properties, he has named it *kinoic acid.* According to Hennig, kino consists of tannic acid with a trace of gallic acid, kinoic acid, pectin, ulmic acid, and inorganic salts with excess of earthy bases (See *Am. Journ. of Pharm.*, xv. 544.)

2. *West India or Jamaica Kino.* This is believed to be the product of the *Coccoloba uvifera*, or *sea-side grape*, a tree twenty feet or more in height, bearing beautiful broad shining leaves, and large bunches of purple berries, to which it owes its vernacular name. It grows in the West Indies and neighbouring parts of the continent. The kino is said to be obtained by evaporating a decoction of the wood and bark, which are very astringent. Many years since, a thick reddish-brown liquid was imported into Philadelphia from the West Indies, which, when dried by exposure to the air in shallow vessels or by heat, afforded an extract having all the properties of kino, for which it was sold by the druggists. This has been long exhausted; but some years since, a consid-

erable quantity of West India kino was brought into this market, which may still enter into the consumption of the country. It was contained in large gourds, into which it was evidently poured while in a liquid or semi-liquid state, and then allowed to harden. We have specimens of this kino in our possession.

When taken from the gourd, it breaks into fragments of various sizes, upon an average about as large as a hazelnut, and having some tendency to the rectangular form. The consistence of these fragments is uniform, their surface smooth and shining, and their colour a dark reddish-brown, approaching to black. They are, however, not so glistening, nor so black as the East India kino. In mass they are quite opaque, but in thin splinters are translucent and of a ruby redness. They are readily broken by the fingers into smaller fragments, are easily pulverized, and yield a dull-reddish powder, considerably lighter-coloured than that of the former variety. The West India kino is without odour, and has a very astringent, bitterish taste, with a scarcely observable sweetish after-taste. It adheres to the teeth when chewed, though rather less than the East India variety, and colours the saliva red. The solubility of Jamaica kino was very carefully examined, at our request, by Dr. Robert Bridges, of this city, who found that cold water dissolved 89 per cent., and ordinary officinal alcohol 94 per cent. The portion dissolved by alcohol and not by water was probably of a resinous nature; as it appeared to be viscid, and very much impeded the filtration of the watery solution. Considering the nature of this substance, the form of kino in which it was found is probably, like that from the East Indies, an inspissated juice. Guibourt, who states that Jamaica kino is but slightly dissolved by cold water, must have operated on a different product.

3. *South American Kino. Caracas Kino.* In 1839, when the 4th edition of this Dispensatory was published, an astringent extract was described, which had recently been introduced into our market, derived, as we were informed, from Caracas, and known by that name to the druggists. Since that period it has come much more extensively into use. It is probably the same as that described by Guibourt, in the last edition of his History of Drugs, as the kino of *Columbia*. As imported, this variety of kino is in large masses, some weighing several pounds, covered with thin leaves, or exhibiting marks of leaves upon their unbroken surface, externally very dark, and internally of a deep reddish-brown or dark port-wine colour. It is opaque in the mass, but translucent in thin splinters, very brittle, and of a fracture always shining, but in some masses wholly rough and irregular, in others rough only in the interior, while the outer portion, for an inch or two in depth, breaks with a rather smooth and uniform surface, like that of the West India kino. This outer portion is easily broken into fine angular fragments, while the interior crumbles quite irregularly. Some of the masses are very impure, containing pieces of bark, wood, leaves, &c.; others are more homogeneous, and almost free from impurities. The masses are broken up by means of a mill so as to resemble East India kino, from which, however, this variety differs in being more irregular, less sharply angular, more powdery, and less black. On comparing the finer and more angular portions of the masses with the West India kino, we were strongly struck with their resemblance; and in fact could discover no difference between the two varieties either in colour, lustre, taste, the colour of the powder, or other sensible property. South American kino was found by Dr. Bridges to yield 93·5 per cent. to cold water, and 93 per cent. to alcohol; so that, while it has almost the same solubility as Jamaica kino in alcohol, it is somewhat more soluble in cold water. The aqueous solution, in this case, was not embarrassed by the adhesive matter which impeded the filtration in the former variety; and the want of a minute proportion of resinous matter in the South American kino is the only difference we have discovered between the two drugs. It is not improbable that they are derived from the same plant; and there is no difficulty in supposing that this may be the Coccoloba uvifera, as that tree grows as well upon the continent as in the islands.

4. *African Kino.* The original kino employed by Dr. Fothergill was known

to be the produce of a tree growing in Senegal, and upon the banks of the Gambia, on the western coast of Africa; but the precise character of the tree was not ascertained until a specimen, sent home by Mungo Park during his last journey, enabled the English botanists to decide that it was the *Pterocarpus erinaceus* of Lamarck and Poiret.* The Edinburgh and Dublin Colleges accordingly referred kino in chief to this plant; but, in so doing, overlooked the fact that not one of the varieties now used is brought from Africa. The importation of African kino has long ceased; and the most experienced pharmacologist cannot speak with certainty of having seen a specimen. That described by Guibourt has turned out to be the *Butea gum*;† and the description in the first edition of Christison's Dispensatory evidently applies to the common East India kino. A specimen given to Dr. A. T. Thomson as African kino, and described in his Dispensatory, is certainly not the drug spoken of by Fothergill, but rather resembles the Butea gum.

As described by Fothergill, the African kino, for which he proposed the name of *gummi rubrum astringens Gambinense*, was in lumps of about the size of those of gum Senegal or dragon's blood, and so similar in appearance to the latter that a good judge might easily be deceived. These lumps were hard, brittle, opaque, and almost black; but minute fragments were reddish and transparent like garnet. The drug was inodorous, of a strongly astringent and sweetish taste, and soluble in water to the extent of about five or six parts out of seven, forming a deep-red astringent infusion. There can be little doubt that this variety of kino is a concrete juice, which exudes either spontaneously or from wounds in the bark, and hardens in the air. (*Med. Obs. and Inq.*, i. 358.)

5. *Botany Bay Kino.* This is the concrete juice of *Eucalyptus resinifera*, or brown gum tree of New Holland, a lofty tree, belonging to the class and order *Icosandria Monogynia*, and the natural order *Myrtaceæ*. This tree attains a very great size, individuals sometimes rising as high as three hundred and forty feet; and an instance is known in which the diameter of the trunk, four feet from the ground, exceeded nineteen feet. The wood, notwithstanding the rapid growth of the tree, is hard and heavy, and well adapted to cabinet work. A specimen of the tree taken to Algeria is flourishing there; and there is little doubt that it might be introduced into our Southern States. (*Am. Journ. of Pharm.*, Sept. 1865, p. 393.) When the bark is wounded, the juice flows very freely, and hardens in the air. According to Mr. White, a single tree is capable of furnishing 500 pounds of kino in one year. (*White's Voyage.*) Duncan states that specimens of the juice have reached Great Britain in the fluid form, and that, when he first examined kino in 1802, it was common, and was the finest kind in commerce. According to information received by Dr. Thomson, its importation into Great Britain must have ceased soon after that period (*Thomson's Dispensatory*, 1826, p. 506); but Dr. Pereira speaks of it as imported in boxes,

* A particular account of Pterocarpus erinaceus and its concrete juice, with a figure by Dr. W. F. Daniell, is contained in the *Pharm. Journ.* for August, 1854 (vol. xiv. p. 55).

† *Butea gum* is the concrete juice of the *Butea frondosa* or *Dhak-tree* of Hindostan. The juice flows from natural fissures, and from wounds made in the bark of the tree, and quickly hardens. It is in small elongated tears, or irregular angular masses, less in size than a grain of barley, apparently black and opaque, but translucent and of a ruby-red colour, when examined in small fragments by transmitted light. Many of the tears have small portions of bark adhering to them. They are very brittle, and readily pulverizable, yielding a reddish powder. They are very astringent to the taste, do not adhere to the teeth when chewed, and tinge the saliva red. The relations of this product to water, alcohol, and other chemical reagents are nearly the same as those of ordinary kino. When freed from impurities, consisting of from 15 to 25 per cent. of wood, bark, sand, &c., it contains, according to Mr. E. Solly, 73·26 per cent. of tannin, 5·65 of soluble extractive, and 21·67 of gum and other soluble substances. It is used in the arts in India, and might undoubtedly be employed as kino in medicine. It is, however, very seldom imported into England, and never, at present, into this country. Dr. Pereira found a quantity in an old drug store in London, and sent a portion to Guibourt, from which that writer drew up his description of African kino. It is possible that the kino which formerly reached us, full of small pieces of wood, bark, &c., may have been the *Butea gum.*

and has himself met with a parcel of it from Van Diemen's Land. Ainslie informs us that he has seen it in the markets of Hindostan. Until after the publication of the tenth edition of this Dispensatory, we had never met with it in this country; but a specimen was afterwards presented to us by Mr. S. W. Osgood, druggist, of New York, with the information that it had been brought to that city in a vessel directly from western Australia.*

The specimen examined by Pereira was in irregular masses, many of them in the form of tears as large as those of Senegal gum. "The purer pieces were vitreous, almost black in the mass, but transparent and of a beautiful ruby-red in small and thin fragments. Some of the pieces, however, were opaque and dull, from the intermixture of wood and other impurities." This variety of kino is brittle, with a resinous unequal fracture, and yields a reddish-brown powder. It is infusible, without odour, of an astringent taste followed by sweetness, and when long chewed adheres to the teeth. (*Duncan.*) It swells up and becomes gelatinous with cold water, yielding a red solution, which gives precipitates with lime-water, gelatin, and sesquichloride of iron, but not with alcohol or tartar emetic. With rectified spirit it also becomes gelatinous, and forms a red tincture, which is not precipitated by water. (*Pereira.*) White states that only one-sixth of this kino is soluble in water; Guibourt found it wholly soluble with the exception of foreign matters; and Dr. Thomson informs us that water at

* Of the specimen presented to us by Mr. Osgood, one portion is in the liquid state, consisting, I presume, of the juice of the tree not yet inspissated, another portion is concrete. The *liquid*, which is contained in a corked and sealed bottle, is of a deep reddish-brown colour, transparent and redder in very thin layers, and somewhat viscid, with a slight solid deposit. The *concrete parcel* consists, for the most part, of very small grains, from the size of powdery particles up to that of a pea. But with these are mixed pieces of a larger size, and two of them comparatively very large, being not less than two or three inches long by an inch, more or less, in breadth and thickness. These latter consist of a thick irregular deposit of the concrete juice on pieces of a thick, spongy, soft, and very brittle bark, which may be easily broken by the nail, and fragments of which of all sizes are mixed with the proper kino, which it resembles in colour, though somewhat lighter. In the irregular angular form of its granules, their dark reddish-brown colour and shining surface, their extreme brittleness and ready pulverization, the reddish colour of their powder, and their astringent bitterish taste, this drug corresponds closely with the more common varieties of kino; and, if deprived of the cortical matter with which it is mingled, might, I have no doubt, be used advantageously for the general purposes of the medicine. If the juice could be imported in quantities, and inspissated here, a pure product might be ensured. Examined at our request by Prof. Procter, this kino formed, when rubbed with water, a soft adhesive mass, and yielded to the water 67 per cent. of its weight in solution; though, as it was very slowly dissolved, more might have been taken up by the water, had the treatment been longer continued. Alcohol of sp. gr. 0·835 dissolved the whole with the exception of 1·5 grains, which might well have been impurity; as particles of the bark may have been embedded in the fragments examined. The tincture was not precipitated by water The watery solution gave precipitates with gelatin, lime-water, sesquichloride of iron, and sulphate of copper, and slight ones with corrosive sublimate and tartar emetic. (*Note to the eleventh edition.*)

The liquid referred to in the preceding paragraph was afterwards examined by Prof. Procter, with the following results. Evaporated to dryness, it yielded 13 per cent. of solid product, resembling kino in appearance and taste. With reagents it acted like a solution of kino, being precipitated copiously by gelatin, acetate of lead, and lime-water, and yielding a greenish-black colour with the salts of sesquioxide of iron. Dr. Pereira found in Botany Bay kino a peculiar pectin-like substance, which he named *eucalyptin*, a characteristic property of which was that it was precipitated from the tincture by solution of ammonia; and Prof. Procter found this juice to act similarly when treated in the same manner. (*Am. Journ. of Pharm.*, May, 1859, p. 228.)—*Note to the twelfth edition.*

A similar liquid is now taken to Europe from Australia, and has been briefly noticed, after M. Stanislas Martin, in the *Journal de Pharmacie* (4e sér., iv. 51, A. D. 1866). It is found, he says, in English commerce, in which it is known by the name of *kino juice*. It has a fine deep-red colour, a slightly aromatic odour, and a decidedly astringent taste, and on evaporation yields a genuine kino. It is not, however, always equally strong, the richest yielding 40 per cent. of extract. New as this product is in commerce, it has already been made the subject of adulteration; a certain proportion of catechu being sometimes added to it during evaporation. The fraud, however, is revealed by the sweet taste imparted to the mixture. (*Note to the thirteenth edition.*)

60° dissolves more than one-half. These writers must have experimented with different substances. According to Dr. Duncan, alcohol dissolves the whole except impurities; and the tincture, with a certain proportion of water, lets fall a copious red deposit, but with a large proportion it only becomes slightly turbid.

It is said that catechu, broken into small fragments, has sometimes been sold as kino. Fortunately, little injury can result from the substitution, as the medical virtues of the two substances are very nearly the same.

Medical Properties and Uses. Kino is powerfully astringent, and in this country is much used for the suppression of morbid discharges. In diarrhœa, not attended with febrile excitement or inflammation, it is often an excellent adjunct to opium and the absorbent medicines, and is a favorite addition to the chalk mixture. It is also used in chronic dysentery when astringents are admissible; in leucorrhœa and diabetes; and in passive hemorrhages, particularly that from the uterus. It was formerly used in intermittent fever.

It may be given in powder, infusion, or tincture. The dose of the powder is from ten to thirty grains. The infusion, which is a very convenient form of administration, may be made by pouring eight fluidounces of boiling water on two drachms of the extract, and straining when cool. Aromatics may be added, if deemed advisable. The dose is a fluidounce. The proportion of alcohol in the tincture renders it frequently an unsuitable preparation.

Locally applied, kino is often productive of benefit. Its infusion is useful as an injection in leucorrhœa and obstinate gonorrhœa, and thrown up the nostrils we have found it very efficacious in suppressing epistaxis. A case of obstinate hemorrhage from a wound in the palate, after resisting various means, yielded to the application of powdered kino, which was spread thickly on lint, and pressed against the wound by the tongue. The powder is also a very useful application to indolent and flabby ulcers.

Krameria triandra. Ruiz and Pavon, *Flor. Peruv.* i. 61. The rhatany plant is a shrub, having a long, much branched, spreading root, of a blackish-red colour; with a round, procumbent, very dark-coloured stem, divided into numerous branches, of which the younger are leafy and thickly covered with soft hairs, giving them a white, silky appearance. The leaves are few, sessile, oblong-ovate, pointed, entire, presenting on both surfaces the same silky whiteness with the young branches. The flowers are lake-coloured, and stand singly on short peduncles at the axils of the upper leaves. There are only three stamens. The nectary consists of four leaflets, of which the two upper are spatulate, the lower roundish and much shorter: it does not correspond with the generic character of Willdenow, which was drawn from the *Krameria Ixina.* The fruit is globular, of the size of a pea, surrounded by stiff reddish-brown prickles, and furnished with one or two seeds. The name *rhatany* is said to express, in the language of the Peruvian Indians, the creeping character of the plant.

This species of Krameria is a native of Peru, growing in dry argillaceous and sandy places, and abundant about the city of Huanuco. It flowers at all seasons, but is in the height of its bloom in October and November. The root is

dug up after the rains. Tschudi states that most of the rhatany now exported is obtained in the southern provinces of Peru, particularly in Arica and Islay. (*Trav. in Peru*, Am ed., p. 214)

The *K. Ixina*, growing in the West Indies and northern parts of South America, affords a root closely analogous in appearance and properties to that of the Peruvian species; but the latter only is officinal. This root is occasionally imported into Europe, and is known in England by the name of *Savanilla rhatany*, derived from the port of New Granada from which it was imported. It has been described by Dr. Mettenheimer of Giessen, and more recently by Dr. Schuchardt of Dresden, whose accounts of it are more particularly referred to in the note below.*

We receive rhatany in pieces of various shapes and dimensions, some being simple, some more or less branched, the largest as much as an inch in thickness, derived from the main body of the root, the smallest not thicker than a small quill, consisting of the minute ramifications. The pieces are often nearly cylindrical, and as much as two or three feet in length. Sometimes many of the radicles are united in a common head, which is short, and from half an inch to two inches or more in diameter. The roots are composed of a dark reddish-brown, slightly fibrous, easily separable bark, and a central woody portion, less coloured, but still reddish or reddish-yellow. Rhatany is without smell, but has a bitter, very astringent, slightly sweetish taste, which is connected with its medical virtues, and is much stronger in the cortical than the ligneous part. The smallest pieces are therefore preferable, as they contain the largest proportion of the bark. The powder is of a reddish colour. The virtues of the root are extracted by water and alcohol, to which it imparts a deep reddish-brown colour. From the researches of Vogel, Gmelin, Peschier, and Trommsdorff, it appears to contain tannic acid, lignin, and minute quantities of gum, starch, saccharine matter, and an acid which Peschier considered as peculiar, and named *krameric acid.* The tannic acid is in three states; 1st. that of purity, in which it is without colour; 2d. that of apotheme, in which it has lost its astringency, and been rendered insoluble by the action of the air, and 3d. that of extractive, which is a soluble combination of tannin and its apotheme, and is the substance which imparts to the infusion and tincture their characteristic reddish-brown colour. (Soubeiran, *Journ. de Pharm.*, xix. 596.) The tannic acid of rhatany (*krameria-tannic* or *rhatania-tannic acid*) is separated by treating the ethereal extract of the bark with alcohol, and evaporating the alcoholic solution. It gives a dark-green precipitate with sesquichloride of iron, a flesh-coloured one with gelatin, and none with tartar emetic. (Gmelin, *Handbook*,

* *Savanilla Rhatany.* Mettenheimer describes a *false rhatany*, which has occurred in German commerce, as follows. The body of the root is from 1 to 2 inches thick and 4 long, knotty, with many branches; but these are generally separate, from 4 to 12 inches long, and nearly half an inch thick. The body resembles the genuine; but the branches are smoother, in parts somewhat shining, with deeper longitudinal furrows, and transverse fissures, which sometimes divide the bark quite around the root. They are more undulating, and, as well as the body, have more frequent wart-like elevations. The false root is more bitter than the genuine, with a thicker bark, and in mass has a dirty violet reddish-brown colour. Exteriorly the bark is of a dirty dark brownish-red, with a granular fracture; interiorly it is lighter coloured, with a fibrous fracture; and when cut with a knife has a shining surface. The ligneous part is pale-red, hard, of a short-fibrous fracture, and, when cut across, dull, and without the dark central point of the genuine root. The false root is inodorous. Its taste is more astringent than that of the genuine. Its source is unknown. (*Pharm. Cent. Blatt*, March 24, 1852, p. 221.)

The foregoing description, which we leave entire, corresponds closely with that of a variety of the drug, known in English commerce as *Savanilla rhatany*, given by Dr. Schuchardt of Dresden, by whom it is referred, in all probability correctly, to *Krameria Ixina* In addition to what has been stated above, it may be mentioned that, in this variety of rhatany, the bark adheres more firmly to the root than in the genuine, that it has a more abrupt and less fibrous fracture, and consequently is more readily pulverized, and that both the wood and bark contain a large proportion of tannic acid. (*Pharm. Journ. and Trans.*, xvi. 29 and 132; from *Botanische Zeitung.*) A root, sent to this city from London, as a specimen of the rhatany known there as Savanilla, corresponds exactly with the description here given. (*Note to the tenth and eleventh editions.*)

xv. 529.) The tannin of rhatany, in the presence of melted potassa, is transformed into *protocatechuic acid* and *phloroglucine*, and with dilute acids gives glucose and a peculiar red colouring principle, called *ratanhia red.* (*Journ. de Pharm. et de Chim.*, Janv. 1868, p. 73.) The proportion of red astringent matter obtained by Vogel was 40 per cent. The mineral acids and most of the metallic salts throw down precipitates with the infusion, decoction, and tincture of rhatany, and are incompatible in prescription.

In examining a specimen of extract of rhatany from America, Wittstein discovered an alkaloid, apparently identical with tyrosine. An analogous result has been obtained by M. Ruge, with the difference, however, that the new alkaloid is not identical with tyrosine, having the formula $C_{26}H_{12}NO_6$, while that of tyrosine is $C_{18}H_{12}NO_6$. (*Journ. de Pharm.*, 4e sér., i. 235; from *Chem. Centralblatt*, 1864, p. 1054.) But much more precise information on the point is required, before it can be admitted that krameria contains an alkaloid.

Cold water, by means of displacement or percolation, extracts all the astringency of rhatany, forming a clear deep-red infusion, which, upon careful evaporation, yields an almost perfectly soluble extract. The root yields its virtues also to boiling water by maceration; but the resulting infusion becomes turbid upon cooling, in consequence of the deposition of apotheme taken up by the water when heated. By boiling with water a still larger proportion of the apotheme is dissolved, and a considerable quantity of the pure tannin becomes insoluble in cold water, and medicinally inert, either by combining with the starch which is also dissolved, or by conversion into apotheme through the agency of the atmosphere. The decoction is, therefore, an ineligible preparation, and the extract resulting from its evaporation, though greater in weight than that from the cold infusion, contains much less soluble and active matter. Alcohol dissolves a larger proportion of the root than water; but this excess is owing to the solution of apotheme, and the alcoholic extract contains little if any more of the astringent principle than that prepared by cold water, while it is encumbered with much inert matter. (See *Extractum Krameriæ.*)

Medical Properties and Uses. Rhatany is gently tonic and powerfully astringent; and may be advantageously given in chronic diarrhœa, passive hemorrhages, especially menorrhagia, some forms of leucorrhœa, and in all those cases in which kino and catechu are beneficial. It has long been used in Peru as a remedy in bowel complaints, as a corroborant in cases of enfeebled stomach, and as a local application to spongy gums. Ruiz, one of the authors of the Peruvian Flora, first made it known in Europe. It was not till after the year 1816 that it began to come into general use. It has the advantage over the astringent extracts imported, that, being brought in the state of the root, it is free from adulteration, and may be prescribed with confidence.

The dose of the powder is from twenty to thirty grains; but in this form the root is little used. The infusion or decoction is more convenient. The proportions are an ounce of the bruised or powdered root to a pint of water, and the dose one or two fluidounces. The extract, tincture, and syrup are officinal, and may be given in the dose, the first of fifteen or twenty grains, the second of two or three fluidrachms, and the third of half a fluidounce. In the form of infusion, tincture, and extract, rhatany has been highly recommended as a local remedy in fissure of the anus, prolapsus ani, and leucorrhœa.

LACTUCA. *Br.*

Lettuce.

The flowering herb of Lactuca virosa. *Br.*

LACTUCARIUM. *U. S.*

Lactucarium.

The concrete juice of Lactuca sativa. *U. S.*

Lactuca. *Sex. Syst.* Syngenesia Æqualis. — *Nat. Ord.* Compositæ Cichoraceæ, *De Cand.* Cichoraceæ, *Lindley.*

Gen. Ch. Receptacle naked. *Calyx* imbricated, cylindrical, with a membranous margin. *Pappus* simple, stipitate. *Seed* smooth. *Willd.*

The plants of this genus yield when wounded a milky juice, to which, indeed, they owe their generic name. In some of them this juice possesses valuable narcotic properties. This is the case, among others, with *L. sativa*, *L. virosa*, and *L. altissima*. It was supposed that our native *L. elongata*, or *wild lettuce*, might have similar virtues; and Dr. Bigelow was informed by physicians who had employed it, that it acts as an anodyne, and promotes the secretion from the skin and kidneys. But, according to M. Aubergier, who experimented with different species of Lactuca, in order to ascertain from which of them lactucarium might be most advantageously obtained, the milky juice of this plant is of a flat and sweetish taste without bitterness, contains much mannite, but no bitter principle, and is destitute of narcotic properties. (*Ann. de Thérap.*, 1843, p. 18.) The probability is that it is nearly or quite inert. Therefore, though formerly holding a place in our national Pharmacopœia, it has been discarded.

Lactuca sativa. Willd. *Sp. Plant.* ii. 1523. The garden lettuce is an annual plant. The stem, which rises above two feet, is erect, round, simple below, and branching in its upper part. The lower leaves are obovate, rounded at the end, and undulating; the upper are smaller, sessile, cordate, and toothed; both are shining, and of a yellowish-green colour. The flowers are pale-yellow, small, and disposed in an irregular terminal corymb. Before the flower-stem begins to shoot, the plant contains a bland, pellucid juice, has little taste or smell, and is much used as a salad for the table; but during the period of inflorescence it abounds in a milky juice, which readily escapes from incisions in the stem, and has been found to possess decided medicinal as well as sensible properties. The juice is more abundant in the wild than the cultivated plants. Inspissated by exposure to the air, it constitutes the lactucarium of our Pharmacopœia. This was formerly recognised by all the British Pharmacopœias; but has been discarded, we think upon insufficient grounds, in the new code.

The original native country of the garden lettuce is unknown. The plant has been cultivated from time immemorial, and is now employed in all parts of the civilized world. It flourishes equally in hot and temperate latitudes. Some botanists suppose that *L. virosa* of the old continent is the parent of all the varieties of the cultivated plant.

Lactuca virosa. Willd. *Sp. Plant.* iii. 1526; Woodv. *Med. Bot.* p. 75, t. 31. The *acrid* or *strong-scented lettuce* is biennial, with a stem from two to four feet high, erect, prickly near the base, above smooth and divided into branches. The lower leaves are large, oblong-obovate, undivided, toothed, commonly prickly on the under side of the midrib, sessile, and horizontal; the upper are smaller, clasping, and often lobed; the bractes are cordate and pointed. The flowers are numerous, of a sulphur-yellow colour, and disposed in a panicle. The plant is a native of Europe.

L. virosa is lactescent, and has a strong disagreeable smell like that of opium, and a bitterish, acrid taste. It was admitted by the late Edinburgh and Dublin Pharmacopœias as one of the sources of lactucarium, which it is said to yield in greater quantity, and of better quality, than the garden lettuce. Mr. Schutz, of Germany, obtained only 17 grains, on the average, from a single plant of the garden lettuce, while a plant of L. virosa yielded 56 grains. The British Pharmacopœia recognises it, but not for the sake of its inspissated juice, which it has discarded.

The milky juice of these species of Lactuca undergoes little alteration, if

confined in closely stopped bottles from which the air is excluded. But, when exposed to the air, it concretes, and assumes a brownish colour somewhat like that of opium. The following mode of collecting it from L. sativa was recommended by Mr. Young, of Edinburgh. When the stem is about a foot high, the top is cut off, and the juice which exudes, being absorbed by cotton or a piece of sponge, is pressed out into a cup or other small vessel, and exposed till it concretes. In order to obtain all the juice which the plant is capable of affording, it is necessary to cut off five or six successive slices of the stem at short intervals, and to repeat the process two or three times a day. The juice may also be collected by the finger as it flows from the incisions.

A plan proposed by Mr. Probart, of London, is to collect the milky juice on pieces of woven cotton about half a yard square, to throw these when fully charged into a vessel containing a small quantity of water, and allow the water thus impregnated to evaporate in shallow dishes at the ordinary atmospheric temperature. The lactucarium is left in the form of an extract.

Another method of extracting the virtues of the lettuce has been recommended by Mr. Probart. When the plant begins to assume a yellow hue, the white juice concretes in the bark of the stem, and in the old leaves, which become very bitter. These parts, being separated, are macerated for twenty-four hours in water, then boiled for two hours; and the clear decoction, having been allowed to drain off through a sieve, is evaporated in shallow vessels by simple exposure. The resulting extract, according to Mr. Probart, has half the strength of lactucarium, and may be obtained at one-sixth of the cost.

The inspissated expressed juice of L. sativa was formerly officinal; but this must be exceedingly uncertain, from the variable quantity of the milky juice contained in the plant; and, as the young leaves, which contain little or none of it, were often employed, the preparation was liable to be quite inert. The *thridace* of Dr. François, at one time supposed to be identical with lactucarium, is in all probability nothing more than the inspissated expressed juice of lettuce, and, indeed, was directed as such in the French Codex of 1837; the leaves being rejected, and the stalks alone, near the flowering period, being subjected to pressure. The present Codex wisely discards the thridace, and admits the proper lactucarium. The Br. Pharmacopœia directs an extract of L. virosa.

M. Aubergier, of Clermont, in a treatise presented to the French Academy of Sciences in November, 1842, states that lactucarium, identical with that of the garden lettuce, can be abundantly and cheaply procured from *Lactuca altissima*, which is a large plant, with a stem more than nine feet high, and an inch and a half in diameter. (*Annuaire de Thérap.*, 1843, p. 18.)

Lactucarium, as brought from England, is in small irregular lumps, about the size of a pea or larger, of a reddish-brown colour externally, and of a narcotic odour and bitter taste. As prepared near Edinburgh, it is commonly in roundish, compact, and rather hard masses, weighing several ounces. (*Christison.*) A variety, known in our market as *German lactucarium*, is in pieces about an inch and a half by an inch in thickness, four-sided, with one side convex and the three others flat, or slightly concave from shrinking, as if quarter sections of a saucer-shaped cake, which had been divided before it was quite dry. The colour on the outer or convex surface is darkish-brown, that of the cut surfaces light yellowish-brown. From experiments by Messrs. Parrish and Bakes, the German appears to be inferior to the English; as 44 per cent. of spirituous extract was obtained from the latter, and only 36 per cent. from the former, while the two extracts were about equal in their sensible properties. (*Am. Journ. of Pharm.*, May, 1860, p. 226.) In colour, taste, and smell lactucarium bears considerable resemblance to opium, and has sometimes been called *lettuce opium*. It does not attract moisture from the air. It yields nearly half its weight to water, with which it forms a deep-brown infusion. From its resemblance in sensible properties and therapeutical effects to opium, it was conjectured to contain morphia, or some analogous principle; but this conjecture has not yet been verified. Buchner, Aubergier, and Walz claim severally to have discovered

the active principle, which has been named *lactucin;* but the substances obtained by these different chemists are not exactly identical in properties; and the lactucin of Walz and Aubergier is considered by M. Lenoir as owing its bitterness to impurities, separated from which it is without taste and inert. It is at least doubtful whether the constituent upon which the medical virtues of lactucarium depend has yet been isolated. We give in a note the results of various analyses of this medicine. They all relate to the lactucarium obtained from Lactuca virosa.*

* Buchner published experiments on lactucarium in 1832. His results are not essentially different from those subsequently obtained. The principle, named by him *lactucin*, is bitter, soluble in water, more soluble in alcohol, less so in ether, without alkaline reaction though precipitated by tannic acid, destitute of nitrogen, capable of forming with acids very soluble bitter combinations, and not easily obtained perfectly white and crystallized. (See *Pharm. Journ.*, vii. 74.)

Dr. Walz, in an inaugural thesis published at Heidelberg in 1839, gives the following constituents of lactucarium from L. virosa; viz., a peculiar principle denominated *lactucin*, volatile oil, a fatty matter easily dissolved by ether, and another of difficult solubility in that fluid, a reddish-yellow tasteless resin, a greenish-yellow acrid resin, common sugar, uncrystallizable sugar, gum, pectic acid, a brown humus-like acid, a brown basic substance, albumen, oxalic, citric, malic, and nitric acids, potassa, lime, and magnesia. Lactucin, as obtained by Walz, is in yellow crystalline needles, inodorous, of a strong and durable bitter taste, easily fusible, soluble in from 60 to 80 parts of cold water, freely soluble in alcohol, less so in ether, soluble in very dilute acids, and without alkaline or acid reaction. (*Annal. der Pharm.*, xxxii. 97.) It was obtained by treating lactucarium with alcohol acidulated with one-fifteenth of concentrated vinegar, adding an equal volume of water, precipitating by subacetate of lead, separating the excess of lead by sulphuretted hydrogen, filtering, evaporating by a gentle heat, treating the residuum by ether, and allowing the solution to evaporate.

M. Aubergier, in his memoir presented to the French Academy in 1842, gives the following as the result of his analysis:—1. a bitter crystallizable substance (*lactucin*), soluble in alcohol and boiling water, scarcely soluble in cold water, insoluble in ether, without alkaline reaction, and supposed to be the active principle; 2. mannite; 3. asparamide; 4. a crystallizable substance having the property of colouring green the sesquisalts of iron; 5. an electro-negative resin, combined with potassa; 6. a neuter resin; 7. ulmate of potassa; 8. cerin, myricin, pectin, and albumen; 9. oxalate, malate, nitrate, and sulphate of potassa, chloride of potassium, phosphate of lime and magnesia, oxides of iron and manganese, and silica. The bitter principle above referred to separates from its solution in boiling water, upon cooling, in pearly scales. By the action of alkalies it loses its bitterness, which is not restored by acids. The lactescence of the fresh juice of lettuce is owing to a mixture of wax and resin, and not to caoutchouc. (*Ann. de Thérap.*, 1843, p. 19.) The bitter principle of Aubergier differs from that of Dr. Walz in being less soluble in cold water, and insoluble in ether.

M. Lenoir considers the lactucin of these two chemists as impure, and denies that it is the active principle, which, he thinks, is probably an organic alkali. He obtained the lactucin pure by treating the lactucarium of L. virosa with boiling alcohol, and filtering while hot. It was deposited on the cooling of the liquid, and afterwards purified by frequent crystallization from alcohol, and treatment with animal charcoal. Thus obtained, it was without taste or smell, and without effect upon the system. It was nearly insoluble in water, but readily dissolved by alcohol, ether, and the volatile and fixed oils. He proposed to name it *lactucone*, leaving the former name for the active principle when isolated. (*Ann. de Chim. et de Phys.*, Feb. 1847.) According to Walz, the lactucone of Lenoir is only the fatty matter discovered by himself. Thieme could not divide this into the two kinds noticed by Walz as differing in their solubility in ether, and, considering it as peculiar, proposed for it the name of *lactucerin*.

The most recent analysis of lactucarium is by Ludwig. That chemist found, in 100 parts, 48·63 of substances insoluble in water, and 51·37 of those soluble in water. Of the insoluble matter 42·64 parts were of *lactucerin* or *lactucone*, which he obtained by first exhausting lactucarium with water, then treating the insoluble residue several times with hot alcohol of 0·833, allowing the alcoholic solution to evaporate slowly, washing the yellowish substance thus procured with water, and purifying it by re-solution in alcohol, and crystallization. Thus obtained, it is in snow-white aggregated granules, dissolves in strong hot alcohol which deposits it on cooling, is readily soluble in ether but insoluble in water, becomes transparent and tenacious when moderately heated in a platinum dish, melts completely at a higher heat with the escape of white odorous vapours, is incapable of saponification by caustic potassa, and is therefore not properly a fat, and in alcoholic solution faintly reddens litmus-paper. It consists of carbon, hydrogen, and oxygen ($C_{40}H_{34}O_5$). Besides this principle there were 3·99 parts of *wax*, and 2·00 of *lignin* and of a substance which swelled in ammonia, and was insoluble in water,

Medical Properties and Uses. That lettuce possesses soporific properties is a fact which was known to the ancients; but Dr. J. R. Coxe, of Philadelphia, enjoys the credit of having first proposed the employment of its inspissated milky juice as a medicine. From experiments with a tincture prepared from lactucarium, Dr. Coxe obtained the same results as usually follow the administration of laudanum. Dr. Duncan, senior, of Edinburgh, afterwards paid particular attention to the subject, and, in his treatise on pulmonary consumption, recommended lactucarium as a substitute for opium, the anodyne properties of which it possesses, without being followed by the same injurious effects. From this recommendation, the medicine came into extensive use, and was adopted as officinal in several of the Pharmacopœias. Dr. François, a French physician, also investigated the medicinal properties of the inspissated juice of lettuce. According to that author, it is sedative, diminishing the rapidity of the circulation, and consequently the temperature of the body, without producing that disturbance of the functions which often follows the use of opium. The general inference which may be drawn from the recorded experience in relation to lactucarium is, that it has, in a much inferior degree, the anodyne and calming properties of opium, without its disposition to excite the circulation, to produce headache and obstinate constipation, and to derange the digestive organs. In this country the medicine is occasionally employed to allay cough, and quiet nervous irritation. It may be given in all cases in which, while opium is indicated in reference to its anodyne or soothing influence, it cannot be administered from idiosyncrasy of the patient. It is, however, very uncertain. The dose is from five to fifteen or twenty grains. An alcoholic extract would be a good preparation. It may be given in the dose of from two to five grains. A syrup is directed in the U. S. Pharmacopœia. (See *Syrupus Lactucarii*, Part II.)*

alcohol, and ether. Of the 51·37 parts soluble in water, 6·98 were *albumen*, 1·75 *lactucerin* held in solution by other substances, 27·68 *bitter extract soluble in water and in alcohol*, and 14·96 *watery extract* insoluble in alcohol of 0·830. The former of these extracts was found to contain a peculiar acid substance called *lactucic acid*, and the lactucin of Aubergier. To obtain these principles, 80 parts of lactucarium, in fine powder, were triturated with 80 of pure cold diluted sulphuric acid, and then mixed with 400 parts of alcohol of 0·851; the liquor was filtered, shaken with hydrate of lime till it yielded no precipitate with baryta-water or oxalate of potassa, then decolorized with pure animal charcoal, and evaporated; the brown tenacious mass thus obtained (alcoholic extract) was treated with boiling water, which left behind a viscid substance; the aqueous solution was treated with animal charcoal, and on being evaporated yielded a mixture of lactucic acid and lactucin; these were separated by dissolving the mixture in boiling water, which on cooling deposited the latter in white crystalline scales, and gave up the former on subsequent evaporation. *Lactucic acid* is of difficult crystallization, light-yellow, strongly bitter, without sour taste, of an acid reaction, and readily soluble in alcohol and water. It has as much claim as any other discovered substance to be considered the active principle of lactucarium. *Lactucin*, purified by animal charcoal, is in white pearly scales, the solution of which exhibits no reaction with subacetate of lead, or solution of iodine. It is dissolved without change of colour by concentrated sulphuric acid. Besides the above ingredients, Ludwig found also in lactucarium *a substance resembling mannite*, *oxalic acid*, *another organic acid* not well determined, a *soft resin*, *potassa*, *magnesia*, and *oxide of iron*. Distilled with diluted sulphuric acid, it gave an acid product smelling like lactucarium, which, saturated with carbonate of lime, and again distilled with bisulphate of potassa, yielded an acid fluid having the odour of valerian. (*Pharm. Cent. Blatt*, June, 1847, p. 438; from *Arch. der Pharm.*, ii. 1 and 129. See also *Am. Journ. of Pharm.*, xx. 57.)—*Note to the eighth edition.*

* Mr. Wm. Hodgson has recommended that lactucarium should be prepared for use by freeing it from a caoutchouc-like principle, which, without possessing any medicinal virtues, interferes with its convenient exhibition. He recommends chloroform for this purpose, but found benzole to answer better, as it removes this tenacious matter without affecting the active principle.

Fluid Extract of Lactucarium. Messrs. Parrish and Bakes propose a *fluid extract*, prepared by completely exhausting lactucarium with diluted alcohol, evaporating the tincture till each fluidounce represents a troyounce of the drug, separating the resinous matter deposited in the course of the evaporation, rubbing this with a little strong alcohol till dissolved, and adding the solution to the fluid extract before the entire completion of the process. Thus prepared, the fluid extract is black, of a heavy narcotic odour, and intensely bitter. Each minim of it represents a grain of the lactucarium. (*Am. Journ. of Pharm.*, May, 1860, p. 229.)—*Note to the twelfth edition.*

Water distilled from lettuce (*eau de laitue*) is used in France as a mild sedative, in the quantity of from two to four ounces. The fresh leaves boiled in water are sometimes employed in the shape of cataplasm. It is said that in Egypt a mild oil is derived from the seeds, fit for culinary use.

The extract or inspissated expressed juice of L. virosa is a sedative narcotic, said also to be gently laxative, powerfully diuretic, and somewhat diaphoretic It is employed in Europe, particularly in Germany, in the treatment of dropsy, and is especially recommended in cases attended with visceral obstruction. It is usually, however, combined with squill, digitalis, or some other diuretic; and it is not easy to decide how much of the effect is justly ascribable to the lettuce. The medicine is never used in this country. The dose is eight or ten grains, which may be gradually increased to a scruple or more. *Lactuca Scariola*, another European species, possesses similar properties, and is used for the same purposes.

LAPPA. *U. S. Secondary.*

Burdock.

The root of Lappa minor. *U. S.*

Bardane, *Fr.;* Gemeine Klette, *Germ.;* Bardana, *Ital., Span.*

ARCTIUM. *Sex. Syst.* Syngenesia Æqualis. — *Nat. Ord.* Compositæ Cinareæ, *De Cand.* Cynaraceæ, *Lindley.*

Gen. Ch. Receptacle chaffy. *Calyx* globular; the scales at the apex with inverted hooks. *Seed-down* bristly, chaffy. *Willd.*

Arctium Lappa. Willd. *Sp. Plant.* iii. 1631; Woodv. *Med. Bot.* p. 32, t. 13. —*Lappa major.* De Cand. *Prodrom.* vi. 661. Burdock is biennial, with a simple spindle-shaped root, a foot or more in length, brown externally, white and spongy within, furnished with thread-like fibres, and having withered scales near the summit. The stem is succulent, pubescent, branching, and three or four feet in height, bearing very large cordate, denticulate leaves, which are green on their upper surface, whitish and downy on the under, and stand on long footstalks. The flowers are purple, globose, and in terminal panicles. The calyx consists of imbricated scales, with hooked extremities, by which they adhere to clothes, and the coats of animals. The seed-down is rough and prickly, and the seeds quadrangular.

This plant, which is the one intended in the Pharmacopœia, is a native of Europe, and is abundant in the United States, where it grows on the roadsides, among rubbish, and in cultivated grounds. Pursh thinks that it was introduced. The root, which should be collected in spring, loses four-fifths of its weight by drying. The odour of the root is weak and unpleasant, the taste mucilaginous and sweetish, with a slight degree of bitterness and astringency. Among its constituents, inulin has been found by Guibourt, and sugar by Fée.

The seeds are aromatic, bitterish, and somewhat acrid.

Medical Properties and Uses. The root is considered aperient, diaphoretic, and diuretic, without irritating properties; and has been recommended in gouty, scorbutic, venereal, rheumatic, scrofulous, leprous, and nephritic affections. Dr. J. Adolphus, of Hastings, Michigan, speaks of burdock in the strongest terms as a remedy in cutaneous diseases. He has treated with it successfully herpes, lepra, psoriasis, prurigo, lupus, and obstinate acne, and thinks nothing equal to it in the cutaneous diseases of children. (*Med. and Surg. Reporter,* March 7, 1868, p. 214.) To prove effectual its use must be long continued. It is administered in the form of decoction, which may be prepared by boiling two ounces of the recent bruised root in three pints of water to two, and given in the quantity of a pint during the day. A fluid extract and syrup have also been prepared from it.* The seeds are diuretic, and have been used in the same complaints,

* *Fluid Extract of Burdock.* This is prepared by Mr. I. J. Graham in the following manner. Sixteen ounces of the root, in moderately fine powder, are first moistened with

in the form of emulsion, powder, and tincture. The dose is a drachm. The leaves have been employed both externally and internally in cutaneous eruptions and ulcerations. W.

LAUROCERASI FOLIA. *Br.*

Cherry-laurel Leaves.

The fresh leaves of Prunus Laurocerasus, the Common or Cherry Laurel. *Br.* Laurier cerise, *Fr.;* Kirschlorbeer, *Germ.;* Lauro ceraso, *Ital.*

Cerasus. *Sex. Syst.* Icosandria Monogynia. — *Nat. Ord.* Amygdaleæ.

Gen. Ch. Differing from Prunus only in its fruit being destitute of bloom, with the stone round instead of acute, and the leaves when in bud folded flat, not rolled up. (Lindley, *Flor. Med.*, 232.)

Cerasus Lauro-cerasus. De Cand. *Prodrom.* ii. 540. — *Prunus Lauro-cerasus.* Willd. *Sp. Plant.* ii. 988; Woodv. *Med. Bot.* p. 513, t. 185. This is a small evergreen tree, rising 15 or 20 feet, with long spreading branches, which, as well as the trunk, are covered with a smooth, blackish bark. The leaves, standing alternately on short strong footstalks, are oval-oblong, from five to seven inches in length, acute, finely-toothed, firm, coriaceous, smooth, beautifully green and shining, with oblique nerves, and yellowish glands at the base. The flowers are small, white, strongly odorous, and disposed in simple axillary racemes. The fruit is an oval drupe, very similar in shape and structure to a small black cherry.

The cherry-laurel is a native of Asia Minor, but has been introduced into Europe, throughout which it is cultivated both for medical use, and for the beauty of its shining evergreen foliage. Almost all parts of it are more or less impregnated with the odour, supposed to indicate the presence of hydrocyanic acid. The leaves only are officinal.

In their recent and entire state they have scarcely any smell; but, when bruised, they emit the characteristic odour of the plant in a high degree. Their taste is somewhat astringent and strongly bitter, with the flavour of the peach kernel. By drying they lose their odour, but retain their bitterness. They yield a peculiar oil and hydrocyanic acid by distillation with water, which they strongly impregnate with their flavour. One pound, avoirdupois, of the fresh leaves yields 40·5 grains of the oil. (*Cent. Blatt*, A. D. 1855, p. 205.) The oil resembles that of bitter almonds, for which it is said to be sometimes sold in Europe, where it is employed to flavour liquors and various culinary preparations; but, as it is highly poisonous, danger may result from its careless use. It has not been determined how far the mode of production of this oil resembles that of bitter almonds. (See *Amygdala Amara.*) Chemists have failed in obtaining amygdalin from the leaves. That the oil exists already formed, to a certain extent, in the fresh leaves, is rendered probable by the fact, stated by Winckler, that they yield it in considerable quantity when distilled without water. (*Journ. de Pharm.*, xxv. 195.) The fresh leaves are used to flavour milk, cream, &c., and more safely than the oil; though they also are poisonous, when too largely employed.

Medical Properties and Uses. The leaves of the cherry-laurel possess properties similar to those of hydrocyanic acid; and the water distilled from them is much employed in various parts of Europe for the same purposes as that active medicine. But it is deteriorated by age, and, therefore, as kept in the shops, must be of variable strength. Hence, while Hufeland directs only twenty drops

diluted alcohol, and then submitted to percolation with the same menstruum until exhausted; one and a half fluidounces of the tincture which first passes being reserved. The remainder of the filtrate is evaporated, by means of a water-bath, to nine fluidounces, to which four ounces of sugar, and, after filtration, the reserved portion are added. A fluidrachm, representing eighty grains of the root, may be given for a dose. (*Am. Journ. of Pharm.*, March, 1860, p. 178.) A *syrup* may be prepared by mixing four fluidounces of this fluid extract with twelve fluidounces of simple syrup, and given in the dose of a tablespoonful. (*Note to the twelfth edition.*)

for a dose every two hours, to be gradually increased to sixty drops, M. Fou quier has administered several ounces without effect. Another source of inequality of strength must be the variable quality of the leaves, according to the time they have been kept after separation from the tree, and probably also to their age and degree of development. Mr. J. Bröker, a Dutch pharmacologist, has satisfied himself, by numerous experiments, that the proportion of hydrocyanic acid in the leaves varies with the season, the age of the plant, the character of the soil and of the weather; and thinks that, in consequence of this variability, they are inferior for medical use to bitter almonds, which in this respect have a more steady constitution. He found the proportion of the acid in the leaves greatest in July, and least in February. (*B. and F. Medico-chir. Rev.*, Oct. 1868, p. 517.) It is not, therefore, to be regretted that the want of the plant in this country has prevented the general introduction of the distilled water into use.

LAVANDULA. *U. S.*

Lavender.

The flowers of Lavandula vera. *U. S.*

Lavande, *Fr.*, Lavandelblumen, *Germ.;* Lavandola, *Ital.;* Espliego, Alhucema, *Span.*

LAVANDULA. *Sex. Syst.* Didynamia Gymnospermia. — *Nat. Ord.* Lamiaceæ or Labiatæ.

Gen. Ch. Calyx ovate, somewhat toothed, supported by a bracte. *Corolla* resupine. *Stamens* within the tube. *Willd.*

Lavandula vera. De Cand. *Flor. Fr. Sup.* p. 398. — *L. Spica.* Willd. *Sp. Plant.* iii. 60; Woodv. *Med. Bot.* p. 321, t. 114. The *Lavandula Spica* of Linnæus includes two distinct species, which were considered by him merely as varieties of the same plant, but have been separated by subsequent botanists. Of these, the officinal plant, the narrow-leaved variety of Linnæus, has been denominated by De Candolle *L. vera*, while the broad-leaved variety still retains the title of *L. Spica.* The latter is scarcely cultivated in the United States.

Common lavender is a small shrub, usually not more than two or three feet high, but sometimes as much as six feet. The stem is woody below, and covered with a brown bark; above, is divided into numerous, slender, straight, herbaceous, pubescent, quadrangular branches, furnished with opposite, sessile, narrow, nearly linear, entire, and green or glaucous leaves. The flowers are small, blue, and disposed in interrupted whorls around the young shoots, forming terminal cylindrical spikes. Each whorl is accompanied with two bractes. The corolla is tubular and labiate, with the lower lip divided into three segments, the upper larger and bifid. The filaments are within the tube.

The plant is a native of Southern Europe, and covers vast tracts of dry and barren land in Spain, Italy, and the south of France. It is cultivated in our gardens, and in this country flowers in August. It is said that in fields, when too thickly planted, it is apt to suffer from a disease consequent on the noxious influence of its own aroma, which is relieved by thinning the plants. (*Pharm. Journ.*, x. 119.) All parts of it are aromatic; but the flowers only are officinal. The spikes should be cut when they begin to bloom.*

Lavender flowers have a strong fragrant odour, and an aromatic, warm, bitterish taste. They retain their fragrance long after drying. Alcohol extracts their virtues; and a volatile oil upon which their odour depends rises with that liquid in distillation. The oil may be procured separate by distilling the flowers with water. (See *Oleum Lavandulæ.*) Hagan obtained from a pound of the fresh flowers from half a drachm to two drachms of the oil.

* For accounts of the cultivation of lavender at Hitchin, in England, see *Pharm. Journ.*, Nov. 1859, p. 276, and the *Boston Med. and Surg. Journ.*, Jan. 14, 1864, p. 481. (*Note to the twelfth edition.*)

Medical Properties and Uses. Lavender is an aromatic stimulant and tonic, esteemed useful in certain conditions of nervous debility, but seldom given in its crude state. The products obtained by its distillation are much used in perfumery, and as adjuvants to other medicines, which they render at the same time more acceptable to the palate, and cordial to the stomach.

Off. Prep. Oleum Lavandulæ; Spiritus Lavandulæ, *U. S.* W.

LEPTANDRA. *U. S.*

Leptandra.

The root of Veronica Virginica (*Linn.*), Leptandra Virginica (*Nuttall*). *U. S.*

LEPTANDRA. *Sex. Syst.* Diandria Monogynia. — *Nat. Ord.* Scrophulariaceæ.

Gen. Ch. Calyx five-parted, segments acuminate. *Corolla* tubular-campanulate, border four-lobed, a little ringent, unequal, the lower lamina narrower. *Stamens* and at length the *pistils* much exserted; filaments below, and tube of the corolla pubescent. *Capsule* ovate, acuminate, two-celled, many-seeded, opening at the summit. *Nuttall.*

The genus Leptandra was separated by Nuttall from the Veronica of Linnæus; and, though the new genus is not universally admitted, and has been rejected in the Manual of Gray, and the Flora of Chapman, yet it has in its favour the distinctive character of its medical properties, and is retained here on this and other considerations.

Leptandra Virginica. Nuttall, *Genera of N. Am. Plants*, i. 7; Rafinesque, *Med. Flora*, vol. ii. — *Veronica Virginica*, Linn.; Gray, *Man. of Bot. &c.* p. 290. This plant, commonly called *Culver's root*, or *Culver's physic*, is a herbaceous perennial, with a simple, erect stem, three or four feet high, smooth or downy, furnished with leaves in whorls, and terminating in a long spike of white flowers. The leaves, of which there are from four to seven in each whorl, are lanceolate, pointed, and minutely serrate, and stand on short footstalks. A variety was seen by Pursh with purple flowers, which was described and figured as a distinct species by Rafinesque, under the name of *L. purpurea.* The plant flowers in July and August. It grows throughout the United States east of the Mississippi, affecting mountain meadows in the South, and rich woods in the North, and not unfrequently cultivated.

The root is the part employed. Under the title of *Veronica*, it was recognised in the first and second editions of the U. S. Pharmacopœia, holding a place in the secondary catalogue; was omitted in the third and fourth editions; and so rapidly had it gained favour in the intervening decennial period, that in the fifth edition it was not only readmitted with the name of Leptandra, but took a place in the primary list.

Properties. The root consists of a rhizoma or root-stalk several inches in length, sometimes branched, with numerous long slender radicles. As brought dried to the shops, the rhizoma is usually broken into pieces an inch or more long, from two to four lines in thickness, either beset with the rootlets or very rough from their remains when broken, very hard and firm, and of difficult fracture, dark-brown externally, light-coloured and ligneous within. The rootlets are round, smooth, slender, generally broken, but, when not so, six inches or more in length, and almost black, being much darker-coloured than the caudex. The odour is feeble and not disagreeable, the taste bitterish, somewhat nauseous, and feebly acrid. Water and alcohol extract the virtues of the root. According to Mr. E. S. Wayne, of Cincinnati, it contains volatile oil, extractive, tannin, gum, resin, and a peculiar crystalline principle, to which the virtues of the medicine may be ascribed. To this principle the name of *leptandrin* properly belongs. Mr. Wayne obtained it by treating an infusion of the root with subacetate of lead, filtering, precipitating the excess of lead by carbonate of soda, filtering to separate the carbonate of lead, passing the filtered liquid through animal charcoal which absorbed all the active matter, washing the charcoal with

water till the washings began to be bitter, then treating it with boiling alcohol, and allowing the alcoholic solution to evaporate spontaneously. By dissolving the powder thus obtained in water, treating this with ether, and allowing the ether to evaporate, needle-shaped crystals were obtained, which had the bitter taste of the root. The resinous matter obtained by making a tincture of the root, and precipitating this with water, has been improperly called leptandrin, and considered the active principle. The pure resin is probably inert; and the preparation referred to owes what activity it may possess to some of the true leptandrin associated with it. Leptandrin is soluble in water, alcohol, and ether. It has not been isolated for use. (*Proceedings of the Am. Pharm. Assoc.*, 1856, p. 34.) Subsequently, Mr. Wayne has obtained from the root a saccharine principle, which he found to have the properties of *mannite* (*Am. Journ. of Pharm.*, Nov. 1859, p. 557); and Prof. F. F. Mayer has extracted a saponaceous principle, closely resembling senegin, which he ascertained to be a glucoside. (*Ibid.*, July, 1863, p. 298.) The chemistry, however, of leptandra needs further investigation.

Medical Properties. The recent root is said to act violently as a cathartic, and sometimes as an emetic. In the dried state it is much milder, but less certain. The practitioners calling themselves Eclectics consider it an excellent cholagogue, and use both the impure resin, which they call leptandrin, and the root itself as a substitute for mercurials. Dr. A. P. Dutcher, of Cleveland, Ohio, after considerable experience with leptandrin, has not found it to act decidedly on the liver, and thinks it, in this respect, a very unsatisfactory substitute for mercury; but believes that it has a special influence on the muciparous follicles of the intestines, and acts very advantageously in cases of duodenal indigestion and chronic constipation. (*Med. and Surg. Reporter*, March 28, 1868, p. 275.) The full cathartic dose of the powder is from twenty grains to a drachm; that of the impure resin referred to, from two to four grains. Dr. J. Adolphus says that, in the dose of one or two grains, the powder acts like rhubarb. On the same authority, from five to ten drops of a strong tincture, given every two hours, produce a mild aperient effect. (*Ibid.*, Jan. 11, 1868, p. 23.) Prof. Procter has prepared a fluid extract of leptandra, which probably contains all its virtues, and may be given as an aperient cholagogue in the dose of from twenty to sixty minims.* W.

LIMONES.

Lemons.

The fruit of Citrus Limonum.

Limons, Citrons, *Fr.;* Limonen, Citronen, *Germ.;* Limoni, *Ital.;* Limones, *Span.*

LIMONIS CORTEX. *U. S., Br.*

Lemon Peel.

The rind of the fruit of Citrus Limonum. *U. S.* The outer part of the rind of the fruit of Citrus Limonum. *Br.*

* The following is the formula referred to in the text. Moisten sixteen troyounces of the powdered root with three fluidounces of a mixture consisting of two parts of alcohol by measure and one of water, pack it in a glass percolator, and pour upon it the diluted alcohol. When a pint of the tincture has passed, set this aside in a warm place, so that it may evaporate to one-half. Continue the percolation until three pints more are obtained, which are to be evaporated on a water-bath to a pint. To this add four ounces of sugar, and, having continued the evaporation till the liquid is reduced to half a pint, add this while hot to the reserved liquid, so as together to make a pint. (*Am. Journ. of Pharm.*, March, 1863, p. 112.)—*Note to the twelfth edition.*

Lemon Juice.

The juice of the fruit of Citrus Limonum. *U. S.* The freshly expressed juice of the ripe fruit. *Br.*

For some general remarks on the genus CITRUS, see *Aurantii Cortex.*

Citrus medica. Willd. *Sp. Plant.* iii. 1426; Woodv. *Med. Bot.* p. 582, t. 189. This tree closely resembles *Citrus Aurantium*, before described. The leaves, however, are larger, slightly indented at the edges, and stand upon footstalks which are destitute of the winged appendages that characterize the other species. The flowers, moreover, have a purplish tinge on their outer surface, and the fruit is entirely different in appearance from the orange. There are several varieties of *Citrus medica*, which some botanists consider as distinct species, but which scarcely differ except in the character of their fruit. Those particularly deserving of notice are the citron, lemon, and lime. 1. In the *citron*, *C. medica* of Risso, the fruit is very large, sometimes six inches in length, ovoidal, with a double rind, of which the outer layer is yellowish, thin, unequal, rugged, with innumerable vesicles filled with essential oil; the inner is white, very thick, and spongy. It is divided in the interior into nine or ten cells, filled with oblong vesicles, which contain an acid juice precisely like that of the lemon, and used for the same purposes. The rind is applied to the preparation of conserves, to which it is adapted by its thickness. The fruit is called *cédrat* by the French. 2. The *lemon* (*C. medica*, var. *limon* of Linn., *Citrus Limonium* of Risso) is smaller than the preceding, with a smoother and thinner rind, a pointed nipple-shaped summit, and a very juicy, acid pulp. In other respects it closely resembles the citron, to which, however, it is usually preferred in consequence of the greater abundance of its juice. 3. The *lime* is still smaller than the lemon, with a smoother and thinner rind, oval, rounded at the extremities, of a pale-yellow or greenish-yellow colour, and abounding in a very acid juice, which renders it highly useful for the purposes to which the lemon is applied. It is the product of the variety *C. acris* of Miller.

The *Citrus medica*, like the orange-tree, is a native of Asia. It was introduced into Europe from Persia or Media, was first cultivated in Greece, afterwards in Italy, so early as the second century, and has now spread over the whole civilized world, being raised by artificial heat where the climate is too cold to admit of its exposure during winter to the open air.

We are supplied with lemons and limes chiefly from the West Indies and the Mediterranean. Though the former of these fruits only is directed by the United States Pharmacopœia, both kinds are employed indiscriminately for most medicinal purposes; and the lime affords a juice at least equal, in proportional quantity and acidity, to that obtained from the lemon.

As lemons rapidly deteriorate on keeping, if exposed to the air, the suggestion of protecting them by a varnish of shellac dissolved in alcohol, made by Mr. George Mee, of London, is not without value. Mr. Mee found that lemons thus covered with varnish continued sound for many months. (See *Am. Journ. of Pharm.*, Sept. 1866, p. 474.)

Properties. The exterior rind of the lemon has a fragrant odour, and a warm, aromatic, bitter taste, somewhat similar to that of the orange, though less agreeable. It contains a bitter principle, and yields, by expression or distillation, an essential oil, which is much used for its flavour. Both this and the rind itself are recognised in the Pharmacopœias. (See *Oleum Limonis.*) When the white spongy portion of the rind is boiled in water, and the decoction evaporated, crystals are deposited, of a substance called *hesperidin*. This is bitter, but, as it is found most largely in the spongy and comparatively tasteless part of the rind, it may be doubted whether it is entitled to be considered as the active bitter principle. (See *Am. Journ. of Pharm.*, xxvi. 553.) Lemon peel yields its virtues to water, wine, and alcohol.

The juice is the part for which the fruit is most esteemed. It is sharply acid, with a peculiar grateful flavour, and consists chiefly of citric acid, mucilage, and extractive, dissolved in water. As lemons cannot always be obtained, the juice is often kept in a separate state; but, from its liability to spontaneous decomposition, it speedily becomes unfit for medical use; and, though various means have been resorted to for its preservation, it can never be made to retain for any length of time its original flavour unaltered. The best medicinal substitute for lemon juice is a solution of crystallized citric acid in water, in the proportion of about an ounce to the pint, with the addition of a little oil of lemons.* One of the most effectual methods of preserving the juice is to allow it to stand for a short time after expression, till a coagulable matter separates, then to filter, and introduce it into glass bottles, with a stratum of almond oil or other sweet oil upon its surface. It will keep still better, if the bottles containing the filtered juice be suffered, before being closed, to stand for fifteen minutes in a vessel of boiling water. Another mode is to add one-tenth of alcohol, and to filter. The juice may also be preserved by concentrating it either by evaporation with a gentle heat, or by exposure to a freezing temperature, which congeals the watery portion, and leaves the acid much stronger than before. When used, it may be diluted to the former strength; but, though the acid properties are retained, the flavour of the juice is found to have been deteriorated. Lemon syrup is another form in which the juice is preserved.

The British Pharmacopœia gives the average sp. gr. of lemon juice at 1·039, and the average quantity of citric acid in a fluidounce of it, 32·5 grains. According to Mr. W. W. Stoddart, these quantities do not correspond; the sp. gr. being too great for the weight of the acid. Mr. Stoddart himself found, in lemons from six different sources, an average of 42·53 grains in an ounce of the juice, and a mean sp. gr. of 1·044. By other authorities the proportions are given very differently. Thus Mr. Watts gives 20·5 grains to the ounce, or 4·7 per cent. of the juice. But the fact is that the quantity of acid varies very greatly. Mr. Stoddart found it to diminish rapidly with the advance of summer, with little change in the sp. gr. (*Pharm. J. and Trans.*, Oct. 1868, p. 203.)

A solution of tartaric acid in water, with the addition of a little sulphuric acid, and flavoured with the oil of lemons, has been fraudulently substituted for lemon juice, particularly as an antiscorbutic on long voyages, for which purpose it is quite useless. An application of the tests for tartaric and sulphuric acid will at once detect the fraud.

Medical Properties and Uses. The rind of the lemon is sometimes used to qualify the taste and increase the power of stomachic infusions and tinctures. The juice is refrigerant, and, properly diluted, forms a refreshing and agreeable beverage in febrile and inflammatory affections. It may be given with sweetened water in the shape of lemonade, or may be added to the mildly nutritive drinks, such as gum-water, barley-water, &c., usually administered in fevers. It is also much employed in the formation of those diaphoretic preparations known by the names of *neutral mixture* and *effervescing draught.* (See *Mistura Potassæ Citratis.*) One of the most beneficial applications of lemon juice is to the prevention and cure of scurvy, for which it may be considered almost a specific. For this purpose, ships destined for long voyages should always be provided with a supply of the concentrated juice, or of crystallized citric acid with the oil of lemons. Lemon juice is sometimes prescribed in connection with opium and Peruvian bark, the effects of which it has been thought to modify favourably, by substituting the citrate of their respective alkalies for the native salts. It has recently been employed with great supposed advantage in acute rheumatism, having been given in quantities varying from one to four fluidounces, from four to six times a day. It has been used with benefit as a local application in pruritus of the scrotum, and in uterine hemorrhage after delivery; and a French

* Nine drachms and a half, dissolved in a pint of water, form a solution of the average strength of lime juice; but, where precision is not requisite, the proportion mentioned in the text is most convenient.

physician, named Revillout, recommends it as a gargle in diphtheric affections of the fauces, though he states that it is without action on the white lenticular patches, which rapidly disappear under chlorate of potassa. (*Ann. de Thérap.*, 1866, p. 213.)

Gen. Ch. Calyx five-leaved. *Petals* five. *Capsule* five-valved, ten-celled. *Seeds* solitary. *Willd.*

Linum usitatissimum. Willd. *Sp. Plant.* i. 1533; Woodv. *Med. Bot.* p. 565, t. 202. Common flax is an annual plant, with an erect, slender, round stem, about two feet in height, branching at top, and, like all other parts of the plant, entirely smooth. The leaves are small, lanceolate, acute, entire, of a pale-green colour, sessile, and scattered alternately over the stem and branches. The flowers are terminal, and of a delicate blue colour. The calyx is persistent, and composed of five ovate, sharp-pointed, three-nerved leaflets, which are membranous on their border. The petals are five, obovate, striated, minutely scalloped at their extremities, and spread into funnel-shaped blossoms. The filaments are also five, united at the base; and the germ, which is ovate, supports five slender styles, terminating in obtuse stigmas. The fruit is a globular capsule, about the size of a small pea, having the persistent calyx at the base, crowned with a sharp spine, and containing ten seeds in distinct cells.

This highly valuable plant, now almost everywhere cultivated, is said by some to have been originally derived from Egypt, by others from the great elevated plain of central Asia. It flowers in June and July, and ripens its seeds in August. The seeds, and an oil expressed from them, are officinal.

The seeds are oval, oblong, flattened on both sides with acute edges, somewhat pointed at one end, about a line in length, smooth, glossy, brown externally, and yellowish-white within. They are inodorous, and have an oily mucilaginous taste. Meyer found in them fixed oil, wax, resin, extractive, tannin, gum, azotized mucilage, starch, albumen, gluten, and various salts. M. Meurein could find no starch, but detected phosphates, which had escaped the notice of Meyer. (*Journ. de Pharm.*, 3e sér., xx. 97.) Their investing coat abounds in a peculiar gummy matter or mucilage, which is readily imparted to hot water, forming a thick viscid fluid, that lets fall white flakes upon the addition of alcohol, and affords a copious dense precipitate with subacetate of lead. By Berzelius the term *mucilage* was applied to a proximate vegetable principle, distinguished from gum by being insoluble in cold, and but slightly soluble in boiling water, in which it swells up and forms a mucilaginous, viscid body, which loses its water when placed upon filtering paper, or other porous substance, and contracts like starch in the gelatinous state. The name, however, is unfortunate; as it is generally applied to the solution of gum, and must inevitably lead to confusion. Nor

is it strictly a distinct proximate principle; as it embraces a number of different bodies, such as bassorin, cerasin, &c. According to Guerin, the mucilage of flaxseed, obtained at a temperature of from 120° to 140°, and evaporated to dryness, by means of a salt-water bath, contains, in 100 parts, 52·70 of a principle soluble in cold water, 29·89 of a principle insoluble in that liquid, and 10·30 of water, and yields 7·11 per cent. of ashes. The soluble part he believes to be arabin or pure gum; the insoluble he found not to afford mucic acid with the nitric, and, therefore, to differ from both bassorin and cerasin. There was also a small proportion of azotized matter which he did not isolate. (*Ann. de Chim. et de Phys.*, xlix. 263.) Vauquelin found free acetic acid, silica, and various salts of potassa and lime. Meurein discovered in the mucilage extracted by cold water, albumen, and a very small proportion of an oleoresin, which resides in the coats of the seeds, and to which they owe their peculiar odour and taste. The interior of the seed, or nucleus, is rich in a peculiar oil, which is separated by expression, and extensively employed in the arts. (See *Oleum Lini.*) According to Franck, the mucilage of flaxseed, and various other similar products, as the mucilage of the quince, the cherry, &c., are not distinct proximate principles, but consist partly of gum and partly of cellulose. (*Journ. de Pharm. et de Chim.*, Dec. 1867, p. 447.)

The ground seeds are kept in the shops under the name of *flaxseed meal.* This is of a dark-gray colour, highly oleaginous, and when mixed with hot water forms a soft adhesive mass, much employed for luting by practical chemists. The cake remaining after the expression of the oil, usually called *oil-cake*, still retains the mucilaginous matter of the envelope, and affords a nutritious food for cattle. This is the *Lini Farina* of the British Pharmacopœia.

Flaxseed is sometimes accidentally or fraudulently mixed with other seeds, especially of plants growing among the flax. We have seen a parcel containing a considerable proportion of the seeds of a species of garlic.*

Medical Properties and Uses. Flaxseed is demulcent and emollient. The mucilage obtained by infusing the entire seeds in boiling water, in the proportion of half an ounce to the pint, is much and very advantageously employed in catarrh, dysentery, nephritic and calculous complaints, strangury, and other inflammatory affections of the mucous membrane of the lungs, intestines, and urinary passages. By decoction water extracts also a portion of the oleaginous matter, which renders the mucilage less fit for administration by the mouth, but superior as a laxative enema. The meal mixed with hot water forms an excellent emollient poultice.

Liriodendron tulipifera. Willd. *Sp. Plant.* ii. 1254; Bigelow, *Am. Med. Bot.* ii. 107; Barton, *Med. Bot.* i. 92. This noble tree is the boast of American land-

* *Light-coloured Flaxseed.* A variety of flax has recently originated, and is now largely cultivated in Ohio, the seeds of which, instead of having the brown colour of ordinary flaxseed, are of a greenish-yellow, and the flower white instead of blue. According to information obtained by Mr. E. L. Wayne, of Cincinnati, the plant is more productive than the common flax; and the seeds are preferred by some in the manufacture of oil. Professor Procter states that, so far as he could judge from a somewhat superficial examination, they differ from the common seeds chemically only in the absence of the brown colouring matter. (*Am. Journ. of Pharm.*, xxvi. 493.)—*Note to the eleventh edition.*

scape. Rising on an erect, straight, cylindrical stem, which is often of nearly equal thickness for the distance of forty feet, it attains, in favourable situations, an elevation seldom less than fifty and sometimes more than one hundred feet, with a diameter of trunk varying from eighteen inches to three feet; and individuals are occasionally met with which greatly exceed these dimensions. The bark is of a brown or grayish-brown colour, except in the young branches, on which it is bluish or of a reddish tinge. The leaves, which stand on long footstalks, are alternate, somewhat fleshy, smooth, of a beautiful shining green colour, and divided into three lobes, of which the upper one is truncated and notched at its summit, so as to present a two-lobed appearance, and the two lower are rounded at the base and usually pointed. In the larger leaves, the lateral lobes have each a tooth-like projection at some distance below their apex. This peculiar form of the leaf serves to distinguish the tree from all others inhabiting the American forests. On isolated trees the flowers are very numerous. They are large, beautifully variegated with different colours, among which yellow predominates, and in appearance bear some resemblance to the tulip, which has given a name to the species. Each flower stands on a distinct terminal peduncle. The calyx is double, the outer two-leaved and deciduous, the inner consisting of three large, oval, concave leaves, of a pale-green colour. The corolla is composed of six, seven, or more obtuse, concave petals. The stamens are numerous, with short filaments, and long linear anthers. The pistils are collected into the form of a cone, the upper part of which is covered with minute stigmas. The fruit consists of numerous long, narrow scales, attached to a common axis, imbricated in a conical form, and containing each two seeds, one or both of which are often abortive.

The tulip-tree extends from New England to the borders of Florida, but is most abundant, and attains the greatest magnitude, in the Middle and Western States. It delights in a rich strong soil, and luxuriates in the exhaustless fertility of the banks of the Ohio and its tributaries. Throughout the United States it is known by the inappropriate name of *American poplar*. When in full bloom, about the middle of May, it presents, in its profusion of flowers, its shining, luxuriant foliage, its elevated stature, and elegant outline; one of the most magnificent objects which the vegetable kingdom affords. The interior or heart-wood is yellowish, of a fine grain, and compact without being heavy; and is much employed in the making of furniture, carriages, door-panels, &c. It is recommended by its property of resisting the influence of atmospheric moisture, and the attacks of worms. The bark is the officinal portion. It is taken for use indiscriminately from the root, trunk, and branches; though that of the root is thought to be most active.

Deprived of the epidermis, it is yellowish white; the bark of the root being somewhat darker than that of the stem or branches. It is very light and brittle, of a feeble, rather disagreeable odour, strongest in the fresh bark, and of a bitter, pungent, and aromatic taste. These properties are weakened by age, and we have found specimens of the bark, long kept in the shops, almost insipid. The peculiar properties of liriodendron appear to reside in a volatile principle, which partially escapes during decoction. The late Professor Emmet, of the University of Virginia, believed that he had isolated this principle, and gave it the name of *liriodendrin*. As described by Professor Emmet, it is, in the pure state, solid, white, crystallizable, brittle, insoluble in water, soluble in alcohol and ether, fusible at 180°, volatilizable and partly decomposed at 270°, of a slightly aromatic odour, and a bitter, warm, pungent taste. It does not unite either with acids or with alkalies; and the latter precipitate it from the infusion of the bark by combining with the matter which renders it soluble in water. Water precipitates it from its alcoholic solution. It is obtained by macerating the root in alcohol, boiling the tincture with magnesia till it assumes an olive-green colour, then filtering, concentrating by distillation till the liquid becomes turbid, and finally precipitating the liriodendrin by the addition of cold water. (*Journ. of the Phil. Col. of Pharm.*, iii. 5.) The virtues of the bark are extracted by water and alcohol, but are injured by long boiling.

Medical Properties. Liriodendron is a stimulant tonic, with diaphoretic properties. It has been used as a substitute for Peruvian bark in intermittent fevers, and has proved serviceable in chronic rheumatism, dyspepsia, and other complaints in which a gently stimulant and tonic impression is desirable. The dose of the bark in powder is from half a drachm to two drachms. The infusion and decoction are also used, but are less efficient. They may be prepared in the proportion of an ounce of the bark to a pint of water, and given in the quantity of one or two fluidounces. The dose of the saturated tincture is a fluidrachm. W.

LITHIÆ CARBONAS. *U. S., Br.*

Carbonate of Lithia.

"A white powder, sparingly soluble in water, and having a feeble alkaline reaction. It dissolves with effervescence in dilute sulphuric acid, and forms a freely soluble salt. It imparts to the flame of burning alcohol a carmine-red colour." *U. S.*

This salt has for the first time been made officinal in the recent editions of the U. S. and Br. Pharmacopœias, in which it is placed in the Materia Medica list, as an article to be obtained from the manufacturer. The alkali *lithia*, so far as has yet been ascertained, is rare in nature; for, though extensively diffused, it exists but in very small proportion, except in a few scarce minerals. It was discovered by Arfwedson in 1817, in certain minerals from the iron mines of Utön, as the *petalite*, *triphane*, and a variety of *tourmaline*. (*Berzelius.*) It has since been found in other minerals, as the *lepidolite*, *spodumene*, *amblygonite*, *mica*, &c., and in numerous mineral waters, as those of Carlsbad, Pyrmont, Kissingen, Kreuznach, Aix-la-Chapelle, Vichy, &c., in Europe, and the Gettysburg spring in the United States, in which it exists generally as a carbonate or bicarbonate. By the spectrum analysis, it has been detected in the waters of the Atlantic and the Thames, the ashes of plants grown on a granite soil, and even in milk and human blood. In the mother-waters of tartaric acid, in the factories, it has been found in a proportion to justify extraction. It has been most largely obtained from a *phosphatic tryphylene*, found in Bavaria, in which it existed as a phosphate; but this source is said to be exhausted.

There are several methods of extracting lithia from the minerals containing it, an account of which may be seen in Gmelin's *Handbook* (iii. 123). They contain the alkali in various proportions, from 3·6 per cent. in lepidolite to 11 per cent. in amblygonite. Carbonate of lithia is prepared from lepidolite in the following manner. One part of the mineral is ignited with two parts of lime; water is added so as to form a paste; this is treated with dilute sulphuric acid, and water is added; the solution is filtered and concentrated; carbonate of soda is added to precipitate earths and metals; the liquor is again concentrated, and, while boiling hot, is treated with carbonate of soda dissolved in twice its weight of water, by which carbonate of lithia is precipitated somewhat impure. To obtain it pure, it is dissolved in very dilute muriatic acid, and the solution precipitated by carbonate of ammonia. (*Gmelin.*)

Lithia, LO, is the oxide of the metal lithium, and ranks in chemical properties with the fixed alkalies. In the form of hydrate, LO,HO, it is white and translucent; does not deliquesce in the air, but absorbs carbonic acid, and becomes opaque; is fusible below ignition, but not volatilizable at a white heat; is soluble in water, but less so than potassa or soda; is sparingly soluble in alcohol; and in solution has an acrid alkaline taste, caustic properties, and a strong alkaline reaction. The salts of lithia are generally freely soluble, with the exception of the neutral carbonate and phosphate, the latter of which is nearly insoluble. *Lithium*, which was first obtained by MM. Bunsen and Matthiessen, in 1855, is silver-white, brilliant, softer than lead, ductile, capable of welding, and the lightest known solid. Its sp. gr. is 0·594, melting point 356° F., equivalent 7, and symbol L. (*Brande and Taylor.*) The eq. of lithia, therefore, is L = 7 + O = 8, or LO = 15; which is the lowest combining number of the fixed alkalies.

Carbonate of lithia may be prepared directly from one of the lithia minerals, in the manner already described, or from sulphate of lithia or chloride of lithium in concentrated solution by adding carbonate of ammonia. The precipitated salt should be washed with alcohol and dried. It is a white powder, of a mild alkaline taste, fusible at a high temperature, soluble in about 100 parts of water, more soluble in carbonic acid water, and insoluble in alcohol. Its aqueous solution has an alkaline reaction. It consists of one eq. of lithia and one of carbonic acid, LO,CO_2, and its eq. is 37. It is known by imparting a carmine-red colour to the flame of alcohol, and by dissolving in dilute sulphuric acid with effervescence; the latter property distinguishing it from the salts of strontia, which also colour the flame of alcohol red. In the British Pharmacopœia, the following test is given. Ten grains, neutralized with sulphuric acid, and heated to redness, leave 14·86 grains of dry sulphate, which, when dissolved in distilled water, yields no precipitate with oxalate of ammonia or lime-water.

Medical Properties and Uses. Carbonate of lithia has the ordinary remedial properties of the alkaline carbonates, over which, however, it possesses advantages, under certain circumstances, which render it a valuable addition to the Materia Medica. In the year 1843, Mr. Alexander Ure, of London, called attention to the extraordinary solvent power of a solution of lithia over uric acid, with which, unlike the other alkalies, it forms a very soluble salt, and suggested its injection into the bladder, for the solution or disintegration of uric acid calculi. In 1857, Dr. Garrod, of London, gave it internally in cases of gout and gouty diathesis, in reference to the same property, as well as in consideration of its low combining number, and consequent extraordinary neutralizing power. From these properties, it is admirably adapted to cases in which it is desirable to eliminate uric acid from the system, and especially to cases of gout, in which there is a strong indication to prevent the formation of insoluble salts of uric acid, and their deposition in the bladder, kidneys, or joints, and to favour the solution of such salts when already formed, as in the chalky deposits in the joints and ligamentous tissues of gouty patients, consisting chiefly of urate of soda. Dr. Garrod has, moreover, found the carbonate of lithia, in dilute solution, not only to exceed the other alkalies in rendering the urine neuter or alkaline, but also to act powerfully as a diuretic, probably more so than the corresponding salts of potassa and soda. (*Med. Times and Gaz.*, March, 1864, p. 303.) The dose of carbonate of lithia is from three to six grains, and is most advantageously given in carbonic acid water.

LOBELIA. *U. S., Br.*

Lobelia.

The herb of Lobelia inflata. *U. S.* The dried flowering herb. *Br.*

Lobelia. *Sex. Syst.* Pentandria Monogynia. — *Nat. Ord.* Lobeliaceæ.

Gen. Ch. Calyx five-cleft. *Corolla* irregular, five-parted, cleft on the upper side nearly to the base. *Anthers* united into a tube. *Stigma* two-lobed. *Capsule* inferior or semi-superior, two or three-celled, two-valved at the apex. *Torrey.*

Lobelia inflata. Willd. *Sp. Plant.* i. 946; Bigelow, *Am. Med. Bot.* i. 177; Barton, *Med. Bot.* i. 181; Carson, *Illust. of Med. Bot.* i. 60, pl. 51. This species of Lobelia, often called *Indian tobacco*, is an annual or biennial indigenous plant, usually a foot or more in height, with a fibrous root, and a solitary, erect, angular, very hairy stem, much branched about midway, but rising considerably above the summits of the highest branches. The leaves are scattered, sessile, oval, acute, serrate, and hairy. The flowers are numerous, small, disposed in leafy terminal racemes, and upon short axillary footstalks. The segments of the calyx are linear and pointed. The corolla, which is of a delicate blue, has a labiate border, with the upper lip divided into two, the lower into three segments. The united anthers are curved, and enclose the stigma. The fruit is

an oval, striated, inflated capsule, crowned with the persistent calyx, and containing, in two cells, numerous very small, brown seeds.*

Lobelia inflata is a very common weed, growing on the roadsides, and in neglected fields, throughout the United States. Its flowers begin to appear towards the end of July, and continue to expand in succession till the occurrence of frost. All parts of it are medicinal; but, according to Dr. Eberle, the root and inflated capsules are most powerful. The plant should be collected in August or September, when the capsules are numerous, and should be carefully dried. It may be kept whole, or in powder. As found in the shops, it is often in oblong compressed cakes, prepared by the Shakers.

Dried lobelia has a slight irritating odour, and when chewed, though at first without much taste, soon produces a burning acrid impression upon the posterior parts of the tongue and palate, very closely resembling that occasioned by tobacco, and attended, in like manner, with a flow of saliva and a nauseating effect. The powder is greenish. The plant yields its virtues readily to water and alcohol. Water distilled from it has its odour without its acrimony. Prof. Procter found the plant to contain an odorous volatile principle, probably volatile oil; a peculiar alkaline principle named lobelina; a peculiar acid, first noticed as distinct by Pereira, called *lobelic acid;* besides gum, resin, chlorophyll, fixed oil, lignin, salts of lime and potassa, and oxide of iron. The seeds contain at least twice as much of lobelina, in proportion, as the whole plant, which yielded only one part in five hundred. They contain also 30 per cent. of a nearly colourless fixed oil, having the drying property in an extraordinary degree. *Lobelina* was obtained by Prof. Procter by the following process. The seeds were treated with alcohol acidulated with acetic acid, until deprived of acrimony, and the tincture was evaporated; the resulting extract was triturated with magnesia and water, and, after repeated agitation for several hours, the liquor, holding lobelina in solution, was filtered; this was then shaken repeatedly with ether until no longer acrid; and the ethereal solution, having been decanted, was allowed to evaporate spontaneously. The residue, which was reddish-brown and of the consistence of honey, was deprived of colouring matter by dissolving it in water, adding a slight excess of sulphuric acid, boiling with animal charcoal, saturating with magnesia, filtering, agitating with ether until this fluid had deprived the water of acrimony, and finally decanting, and allowing the ether to evaporate. Thus obtained, *lobelina* is a yellowish liquid, lighter than water, of a somewhat aromatic odour, and a very acrid durable taste. It is soluble in water, but much more copiously in alcohol and ether; and the latter fluid readily removes it from its aqueous solution. It has an alkaline reaction, and forms soluble and crystallizable salts with sulphuric, nitric, and muriatic acids, and a very soluble but not crystallizable salt with acetic acid. It forms an insoluble compound with tannic acid, which instantly precipitates it from its solution. By a boiling heat it is entirely decomposed, losing all its acrimony; but, when combined with acids, it may be subjected to ebullition with water without change. Prof. Procter introduced a grain of it diluted with water into the stomach of a cat, which became immediately prostrate, remained for an hour nearly motionless, with dilated pupils, and had not wholly recovered at the end of fifteen hours. It did not occasion vomiting or purging. There can be little doubt that it is the narcotic principle of lobelia. (*Am. Journ. of Pharm.*, ix. 105, and xiii. 1.)† The

* In case of poisoning by lobelia, it may be very desirable to be able to recognise the seeds. The following microscopic characters of them are given by Mr. Frederick Curtis in the *Lond. Med. Gaz.* for July, 1851 (p. 160). They are almond-shaped, about 1-30th of an inch long by 1-75th broad, puce-coloured, regularly marked with longitudinal ridges and furrows, and cross ridges generally at right angles with the former; so that the surface presents the appearance of basket-work. No other seeds examined by the author could be mistaken for them, except those of *Lobelia cardinalis*, which, however, are larger, coarser, of a lighter colour, and with the superficial rectangular chequering less distinct. (*Note to the tenth edition.*)

† Mr. William Bastick, of London, published in the *Pharmaceutical Journal and Transactions* for December, 1850, an account of lobelina and its mode of extraction, ap-

late Dr. S. Colhoun, of Philadelphia, was the first to announce the existence of a peculiar principle in lobelia, capable of forming salts with the acids; but he did not obtain it in an isolated state. An important inference from the effects of heat upon lobelina is, that, in preparing lobelia for use, the plant should never be heated in connection with a salifiable base.

Medical Properties and Uses. Lobelia is emetic, and, like other medicines of the same class, is occasionally cathartic, and in small doses diaphoretic and expectorant. It is also possessed of narcotic properties. The leaves or capsules, chewed for a short time, occasion giddiness, headache, general tremors, and ultimately nausea and vomiting. When swallowed in the full dose, the medicine produces speedy and severe vomiting, attended with continued and distressing nausea, copious sweating, and great general relaxation. Its effects in doses too large, or too frequently repeated, are extreme prostration, great anxiety and distress, and ultimately death preceded by convulsions. Dr. Letheby found 110 grains of it in the stomach of a patient killed by this poison, and states that he has known much less to cause death. (*Lond. Med. Times and Gaz.*, March, 1853, p. 270.) From experiments made by Mr. Curtis and Dr. Pearson on hedgehogs and cats, it would appear that the poison produces inflammation of the alimentary mucous membrane in those animals, but that death mainly results from the suspension of respiration; the heart continuing to act after that process has ceased. It is probable that it paralyzes, by a directly depressing influence, the respiratory centres in the medulla oblongata. Death has often resulted from its empirical use. Its poisonous effects are most apt to occur, when, as sometimes happens, it is not rejected by vomiting. In its action upon the system, therefore, as well as in its sensible properties, lobelia bears a close resemblance to tobacco. It is among the medicines which were employed by the aborigines of this country, and was long in the hands of empirics before it was introduced into regular practice. The Rev. Dr. Cutler, of Massachusetts, first attracted to it the attention of the profession.

Merely as an emetic, it is too powerful and distressing, as well as too hazardous in overdoses, for ordinary use. The disease in which it has proved most useful is spasmodic asthma, the paroxysms of which it often greatly mitigates, and sometimes wholly relieves, even when not given in doses sufficiently large to vomit. It was from the relief obtained from an attack of this complaint in his own person, that Dr. Cutler was induced to recommend the medicine. It has been used also in catarrh, croup, pertussis, and other laryngeal and pectoral affections; and we have seen it apparently advantageous in some of these complaints, especially in severe croup, and in chronic bronchitis with dyspnœa; but it should always be used with caution. Administered by injection it produces the same distressing sickness of stomach, profuse perspiration, and universal relaxation, as result from a similar use of tobacco. Dr. Eberle administered a strong decoction of it successfully by the rectum in a case of strangulated hernia. It has been employed effectually, in small doses repeated so as to sustain a slight nausea, for producing relaxation of the os uteri. (*Am. Journ. of Med. Sci.*, xvii. 248.) A case is recorded in the *Charleston Med. Journ. and Rev.* (xi. 58), by Dr. Gaston, of Columbia, S. C., in which the tincture of lobelia was successfully used in tetanus.

It may be given in substance, tincture, or infusion. The dose of the powder as an emetic is from five to twenty grains, to be repeated if necessary. The tincture is most frequently administered. The full dose of this preparation for an adult is half a fluidounce; though in asthmatic cases it is better administered in the quantity of one or two fluidrachms, repeated every two or three hours till its effects are experienced.*

parently in entire ignorance of the previous experiments and observations of Prof. Procter. His process does not differ essentially from that above given. In one magnesia is used to decompose the native salt of lobelina, in the other lime; the caustic alkalies not being applicable to the purpose, as they decompose this organic alkali with great facility. (*Note to the ninth edition.*)

* Professor Procter prepares a *fluid extract* by macerating eight ounces of finely bruised

Two other species of Lobelia have attracted some attention from medical writers. *L. cardinalis* or *cardinal flower*, distinguished for its showy red flowers, is supposed to possess anthelmintic properties; but is seldom used. *L. syphilitica* is said to have been used by the Indians in the cure of syphilis, but has been found wholly inefficacious in that complaint. It is emetic and cathartic, and appears also to possess diuretic properties; whence it has been conjectured that it might have proved serviceable in gonorrhœa. Dr. Chapman states that it has been employed, as he has been informed, by some practitioners of the western country in dropsy, and not without success. The root is the part used. Both these species of Lobelia are indigenous. For a more detailed account of them, the reader is referred to Dr. W. P. C. Barton's Medical Botany.

Lycopodium. *Sex. Syst.* Cryptogamia Filices. — *Nat. Ord.* Lycopodiaceæ.

Gen. Ch. Thecæ unilocular, of one or two forms; that containing powder somewhat reniform and two-valved, the other roundish, three or four-valved. *Lindley.*

Lycopodium clavatum. Linn. *Sp. Plant.* 1564; Smith, *Engl. Flor.* iv. 331. This plant, commonly called *club-moss*, has a trailing, branching stem, several feet long, and thickly beset with linear-lanceolate, flat, ribless, smooth, partly serrate leaves, with a capillary point, curved upward, and of a deep-green colour. The flowers are in terminal spikes, single or in pairs, with crowded ovate, entire, pointed scales, and yellow thecæ or capsules. The plant is a native of Europe and this country.

The capsules of this moss, and of others belonging to the same genus, contain a fine dust or powder, which is collected in Switzerland and Germany, and used in the shops of Europe under the name of *lycopodium* or *vegetable sulphur*. It is this that constitutes the officinal part of the plant, of which it is the seeds or sporules. It is extremely fine, very light, of a delicate yellow colour, inodorous and tasteless, and exceedingly inflammable, so much so that it takes fire like gunpowder when thrown upon a burning body. Under the microscope, it is found to be composed of cells, which, on pressure between glasses, give out a transparent fluid, resembling oil. (*Ed. Monthly Journ.*, Nov. 1854, p. 469.) It is said to be often adulterated with the pollen of the pines and firs, and sometimes with talc and starch. In medicine, it is used as an absorbent application to excoriated surfaces, especially those which occur in the folds of the skin in infants. In pharmacy, it answers the purpose of facilitating the rolling of the pilular mass, and of preventing the adhesion of the pills when formed. The moss itself has

lobelia, mixed with a fluidounce of acetic acid, in a pint and a half of diluted alcohol, for twenty-four hours; then percolating with an equal quantity of diluted alcohol, and afterwards with water, until three pints of liquor are obtained; next evaporating to ten fluidounces, straining, adding six fluidounces of alcohol, and finally filtering through paper. Each teaspoonful of this preparation is equal to half a fluidounce of the tincture, which represents about 30 grains of the powder. (*Am. Journ. of Pharm.*, xxiv. 207.)—*Note to the tenth edition.*

been esteemed diuretic, antispasmodic, &c.; and has been employed, in the form of decoction, in rheumatism, epilepsy, and complaints of the lungs and kidneys; and has been supposed to be of great service in the removal of plica Polonica. It has, however, fallen into discredit. W.

LYCOPUS. *U. S. Secondary.*

Bugle-weed.

The herb of Lycopus Virginicus (*Michaux*). *U. S.*

Lycopus. *Sex. Syst.* Diandria Monogynia. — *Nat. Ord.* Lamiaceæ or Labiatæ. *Gen. Ch. Calyx* tubular, five-cleft or five-toothed. *Corolla* tubular, four-lobed, nearly equal; the upper segment broader, and emarginate. *Stamens* distant. *Seeds* four, naked, retuse. *Nuttall.*

Lycopus Virginicus. Michaux, *Flor. Boreal. Americ.* i. 14; Rafinesque, *Med. Flor.* vol. ii. The *bugle-weed* is an indigenous herb, with a perennial creeping root, which sends up an erect, nearly simple, obtusely quadrangular stem, from twelve to eighteen inches high, and furnished with opposite sessile leaves. These are broad-lanceolate, attenuated and entire at both extremities, remotely serrate in the middle, somewhat rough, purplish, and beset with glandular dots on their under surface. The flowers are minute, in small axillary whorls, with two small subulate bractes to each flower, and a white corolla. The seeds are longer than the calyx, which is spineless.

This plant grows in shady and wet places throughout the greater part of the United States. Its flowering period is August. The whole herb is used. It has a peculiar odour and a nauseous slightly bitter taste, and imparts these properties, as well as its medical virtues, to boiling water.

Lycopus Europæus is said to be frequently collected and sold for *L. Virginicus*. The former may be distinguished by its acutely quadrangular stem, its narrow lanceolate leaves, of which the lower are somewhat pinnatifid, its more crowded flowers, and the acute segments of its calyx, armed with short spines. It has been employed in Europe as a substitute for quinia.

Medical Properties and Uses. According to Dr. A. W. Ives, the bugle-weed is a very mild narcotic. It is said also to be astringent. It was introduced into notice by Drs. Pendleton and Rogers, of New York, who obtained favourable effects from it in incipient phthisis and pulmonary hemorrhage. (*N. Y. Med. and Phys. Journ.*, i. 179.) It proves useful by diminishing the frequency of the pulse, quieting irritation, and allaying cough. The use of it has been extended with advantage to the hemorrhages generally. (*Transact. of the Am. Med. Assoc.*, i. 347.) It is most conveniently employed in the form of infusion, which may be prepared by macerating an ounce of the herb in a pint of boiling water. From half a pint to a pint may be taken daily. W.

MAGNESIÆ CARBONAS. *U. S., Br.*

Carbonate of Magnesia.

"A white substance in powder or pulverulent masses, wholly dissolved by dilute sulphuric acid, forming a solution which does not afford a precipitate with oxalate of ammonia. Distilled water which has been boiled with it does not change the colour of turmeric, and yields no precipitate with chloride of barium or nitrate of silver." *U. S.*

Magnesia alba, *Lat.;* Carbonate de magnésie, *Fr.;* Kohlensaure Magnesia, *Germ.;* Carbonato di magnesia, *Ital.;* Carbonato de magnesia, *Span.*

Carbonate of magnesia sometimes though rarely occurs as a native mineral. That which is sold in the shops is prepared on a large scale by the manufacturer; and the article is, therefore, very properly placed in the list of Materia Medica of the U. S. Pharmacopœia. In the British Pharmacopœia directions are given for preparing it in two forms; that of Magnesiæ Carbonas, or *Car-*

bonate of Magnesia; and that of MAGNESIÆ CARBONAS LEVIS, or *Light Carbonate of Magnesia.* The following are the directions.

1. MAGNESIÆ CARBONAS. *Carbonate of Magnesia. Br.* "Take of Sulphate of Magnesia *ten ounces* (avoirdupois); Carbonate of Soda *twelve ounces* (avoird.); Boiling Distilled Water a *sufficiency.* Dissolve the Sulphate of Magnesia and Carbonate of Soda, each, in a pint [Imp. Meas.] of the Water, mix the two solutions, and evaporate the whole to perfect dryness, by means of a sand-bath. Digest the residue for half an hour with two pints [Imp. Meas.] of the Water, and, having collected the insoluble matter on a calico filter, wash it repeatedly with Distilled Water, until the washings cease to give a precipitate with chloride of barium. Finally, dry the product at a temperature not exceeding 212°." *Br.*

This is essentially the old process of the Dublin College for MAGNESIÆ CARBONAS PONDEROSUM, or *Heavy Carbonate of Magnesia,* and yields a product which is characterized, in the British Pharmacopœia, as "a white granular powder, which dissolves with effervescence in the dilute mineral acids, yielding solutions which, when first treated with chloride of ammonium, are not disturbed by the addition of an excess of solution of ammonia, but yield a copious crystalline precipitate upon the addition of phosphate of soda. With excess of hydrochloric acid it forms a clear solution, in which chloride of barium causes no precipitate. Another portion of the solution, supersaturated with ammonia, gives no precipitate with oxalic acid or sulphuretted hydrogen. Fifty grains, calcined at a red heat, are reduced to twenty-two."

2. MAGNESIÆ CARBONAS LEVIS. *Light Carbonate of Magnesia. Br.* The same quantity of materials are taken as in the preceding formula, the Distilled Water being now cold instead of boiling. The two salts are dissolved separately, each in half a gallon (Imp. Meas.) of the Water, the solutions are mixed, and the mixture is boiled in a porcelain dish for fifteen minutes. The precipitate is then washed and dried as in the former process. The resulting carbonate is characterized, in the Br. Pharmacopœia, as "a very light powder, which, when examined under the microscope, is found to be partly amorphous with numerous slender prisms intermixed. The other characters are the same as those of carbonate of magnesia."

Carbonate of potassa is less eligible than carbonate of soda for the preparation of carbonate of magnesia. It is difficult to separate the last portions of sulphate of potassa from the precipitate, and carbonate of potassa usually contains silica, which is thrown down with the magnesia. The consequence is that, when prepared with that salt, carbonate of magnesia is liable to be gritty to the touch, and to have a saline taste. The following method is said to be pursued by some of the best manufacturers. To a saturated solution of 100 parts of sulphate of magnesia, a solution of 125 parts of crystallized carbonate of soda is gradually added, the solutions being constantly stirred. The mixture is heated to ebullition, to complete the precipitation of the magnesia, which is then washed with tepid and finally with cold water, until the washings no longer give a precipitate with barytic salts. When sufficiently washed, the carbonate is allowed to drain for one or two days on large linen filters, and is then placed in wooden moulds with a porous bottom of brick or gypsum, and subjected to pressure in order to give it a square and compact form.

The density of carbonate of magnesia is said to depend upon the strength of the solutions from which it is first precipitated, and its fineness and softness to the touch, upon the use of carbonate of soda in its preparation.

Much of the carbonate of magnesia used in this country is imported from Scotland. In New England it is prepared from the bittern of salt-works, which consists chiefly of sulphate of magnesia and chloride of magnesium; and it is manufactured in Baltimore from the sulphate of magnesia prepared in that city. The Scotch magnesia is generally put up in cases of 120 lbs. each, the American, in boxes containing 50 lbs.*

* Carbonate of magnesia is now largely prepared in Great Britain by submitting calcined magnesian limestone to the action of water and carbonic acid under pressure. The

When made from the bittern of salt-works, carbonate of magnesia is contaminated with carbonate of lime, salts of that earth being contained in sea-water; and, when it is prepared from magnesite, or from magnesian schist, iron is almost always present. The only way in which these impurities can be avoided, is to prepare pure sulphate of magnesia by repeated crystallization, and to use a pure carbonate of soda. It is also necessary that the water with which the precipitate is washed should be free from earthy salts, which would be decomposed and contaminate the magnesia.

Properties. Carbonate of magnesia is inodorous, nearly insipid, perfectly white, smooth to the touch, and nearly insoluble in water, requiring 2493 parts of cold, and 9000 parts of hot water for solution. It is decomposed by strong heat, by all the acids, by potassa, soda, lime, baryta, and strontia, and by acidulous and metallic salts.

Two kinds of carbonate of magnesia are distinguished, the light and the heavy. The *light carbonate* is the kind manufactured in Scotland. The British process for the *heavy* has been already given. It may also, according to Dr. Pereira, be prepared as follows. "Add one volume of a cold saturated solution of carbonate of soda to a boiling mixture of one volume of a saturated solution of sulphate of magnesia, and three volumes of water. Boil until effervescence has ceased, constantly stirring with a spatula. Then dilute with boiling water, set aside, pour off the supernatant liquor, and wash the precipitate with hot water on a linen cloth: afterwards dry it by heat in an iron pot." Dr. Pereira states that the *light carbonate*, when examined with the microscope, is seen to consist of an amorphous powder, more or less intermingled with slender prismatic crystals, which appear as if they were eroded or efflorescent; the *heavy carbonate* consists of granules of various sizes, without any traces of the prismatic crystals observed in the former variety.

A solution in carbonic acid water, prepared by passing carbonic acid gas into a reservoir containing carbonate of magnesia suspended in water, has been introduced into use as a cathartic and antacid. *Dinneford's Magnesia* is a solution of this nature. According to Dr. Christison, it contains only nine grains of carbonate in the fluidounce, though alleged to contain twice that quantity. Its taste is more disagreeable than that of the undissolved carbonate. A formula for this preparation has been introduced into the British Pharmacopœia, with the name of "Liquor Magnesiæ Carbonatis," and will be found in *Part* II.

Adulterations and Tests. Carbonate of magnesia may contain an alkaline carbonate or sulphate, or both, from insufficient washing; also chloride of sodium, alumina, and carbonate of lime. If water boiled on it changes turmeric, an alkaline carbonate is indicated. If chloride of barium produces a precipitate in the water, the presence of a sulphate or carbonate is shown; and if nitrate of silver produces the same effect, a chloride is indicated. When dissolved in an excess of muriatic acid, an excess of ammonia will throw down alumina, which is almost always present in minute quantity; and oxalate of ammonia, afterwards added to the filtered muriatic solution, will throw down oxalate of lime, if that earth be present. If the same solution, nearly neutralized, be rendered blue by ferrocyanide of potassium, the presence of iron will be indicated.

Composition. According to Berzelius, carbonate of magnesia of the shops (*magnesia alba*) is a combination of three eqs. of carbonate of magnesia with one of hydrate of magnesia. Each eq. of carbonate contains an eq. of water, and the composition of the salt may be thus stated:—three eqs. of carbonate (acid 66, magnesia 60, water 27) = 153 + one eq. of hydrate (magnesia 20, water 9) = 29 = 182. This theoretic composition agrees nearly with the analysis of Berzelius, who fixes it at 44·75 magnesia, 35·77 acid, and 19·48 water. According to Phillips, whose analysis agrees with a subsequent one by Fownes, four eqs. of the carbonate are combined with one of the bihydrate, and four of water.

magnesia is dissolved in the state of bicarbonate, and heat is applied to the solution, so as to drive off a portion of the carbonic acid, and to cause thereby a precipitation of the insoluble carbonate. (*Chem. News*, Sept. 12, 1863, p. 128.)—*Note to the twelfth edition.* W.

(*Pharm. Journ.*, iii. 480.) The formula given by the British Pharmacopœia is $3(MgO,CO_2)+MgO,5HO$; in other words, a combination of 3 eqs. of carbonate of magnesia, one of magnesia, and five of water. The composition of this salt varies with the mode of preparation. Thus Bucholz, by decomposing sulphate of magnesia with 170 per cent. of carbonate of soda, and using only cold water throughout, obtained a very light, spongy, somewhat coherent carbonate of magnesia, containing 32 acid, 33 base, and 35 water. By using 120 per cent. of the carbonate, and boiling for fifteen minutes, he obtained a heavy, granular precipitate, containing 35 acid, 42 base, and 23 water.

Medical Properties and Uses. Carbonate of magnesia is antacid, and, by combining with acid in the stomach, becomes generally cathartic. When it undergoes no change in the alimentary canal, it produces no purgative effect. Under these circumstances, it may usually be made to operate by following it with draughts of lemonade. It is useful in all cases which require a laxative antacid; and, though apt to produce flatulence in consequence of the extrication of its carbonic acid in the stomach and bowels, and therefore in ordinary cases inferior to calcined magnesia, it sometimes operates favourably, in consequence of this very property, in sick stomach attended with acidity. Carbonate of magnesia is also an excellent antilithic when uric acid is secreted in excess. The dose is from half a drachm to two drachms, which may be given in water or milk. In order that it may be accurately diffused through water, it should be previously rubbed down with syrup or ginger syrup.*

Carbonate of magnesia is a useful agent for diffusing camphor and the volatile oils through water, in preparing several of the medicated waters.

Off. Prep. Liquor Magnesiæ Carbonatis, *Br.;* Magnesia; Trochisci Bismuthi, *Br.* D. B. S.

MAGNESIÆ SULPHAS. *U. S., Br.*

Sulphate of Magnesia.

"In colourless crystals, which slowly effloresce on exposure to the air, and are very soluble in water. The solution is not coloured nor precipitated by ferrocyanide of potassium, and gives off no muriatic acid upon the addition of sulphuric acid. One hundred grains of the salt dissolved in water, and mixed with sufficient boiling solution of carbonate of soda to decompose it completely, yield a precipitate of carbonate of magnesia, which, when washed and dried, weighs thirty-four grains." *U. S.*

Epsom salt; Sulfate de magnésie, *Fr.;* Schwefelsaure Magnesia, *Germ.;* Solfato di magnesia, *Ital.;* Sulfato de magnesia, *Span.*

Sulphate of magnesia is a constituent of sea-water, and of some saline springs. It also occurs native, either crystallized in slender, prismatic, adhering crystals, or as an efflorescence on certain rocks and soils, which contain magnesia and a sulphate or sulphuret. In the United States it is found in the great caves, so numerous to the west of the Alleghany mountains. In one of these caves, near Corydon in Indiana, it formed a stratum on the bottom several inches deep; or appeared in masses sometimes weighing ten pounds, or disseminated in the earth of the cavern, one bushel of which yielded from four to twenty-five pounds of the sulphate. It also appeared on the walls of the cavern, and, if it was removed, acicular crystals again appeared in a few weeks. (*Cleaveland.*)

Sulphate of magnesia was originally procured by evaporating the waters of saline springs at Epsom in England. Dr. Grew prepared it in this manner in 1675. It was afterwards discovered that the brine, remaining after the crystallization of common salt from sea-water, furnished by careful evaporation precisely the same salt; and, as this was a much cheaper product, it superseded the former. The residual brine or bittern consists of sulphate of magnesia, and

* *Dalby's carminative* consists of carbonate of magnesia ℈ij, oil of peppermint ♏j, oil of nutmeg ♏ij, oil of aniseed ♏iij, tincture of castor ♏xxx, tincture of assafetida ♏xv, tincture of opium ♏v, spirit of pennyroyal ♏xv, compound tincture of cardamom ♏xxx, peppermint water f℥ij.

the chlorides of magnesium and calcium. As the sulphate of magnesia crystallizes first, it may with proper care be obtained nearly pure, although most frequently the salt prepared in this way is deliquescent from the presence of chloride of magnesium. It may be freed from this impurity by washing the crystals with its own saturated solution. It was from this source that the greater part of the Epsom salt of commerce was long obtained in Europe. The salt works of New England supplied our own markets with an impure and deliquescent sulphate. With the improvements of chemistry, other and better processes have been adopted. In the neighbourhood of Genoa and Nice, sulphate of magnesia is prepared in large quantities from a schistose rock, containing magnesia and sulphuret of iron. The mineral is roasted, and exposed in heaps for some months to the action of air and water. It is then lixiviated, the sulphate of iron decomposed by lime-water, and the salt obtained pure by repeated solution and crystallization.

William Henry, of Manchester, whose calcined magnesia has become famous throughout the world, took out a patent for a mode of preparing magnesia and its salts from the double carbonate of magnesia and lime—the *dolomite* of mineralogists. His process was to drive off the carbonic acid by heat, and to convert the remaining earth into hydrates. He treated these with a sufficient quantity of muriatic acid to dissolve out the lime, and then converted the magnesia into a sulphate either by sulphuric acid or sulphate of iron.

The salt is extensively manufactured in Baltimore and Philadelphia from the silicious hydrate of magnesia, or *magnesite*. This mineral occurs in veins in the serpentine and other magnesian rocks which abound in the neighbourhood of Baltimore, and in the southern counties of Pennsylvania. The advantage which it possesses over the dolomite, in the preparation of this salt, is the almost entire absence of lime, owing to which there is little or no waste of acid, and the operation is much simplified. The mineral is reduced to a fine powder and saturated with sulphuric acid. The mass is then dried and calcined at a red heat, in order to convert any sulphate of iron, which may be present, into red oxide. It is then dissolved in water, and sulphuret of lime added to separate any remaining portion of iron. The salt is crystallized and dissolved a third time, in order to purify it. The sulphate prepared by this process is generally very pure and clean, although it sometimes contains sulphate of iron.

Properties, &c. Sulphate of magnesia is a colourless transparent salt, without smell, and of a bitter, nauseous, saline taste. It crystallizes in quadrangular prisms, terminating in a four-sided pyramid or in a dihedral summit It usually occurs in small acicular crystals, which are produced by agitating the solution while crystallizing. It slowly effloresces in the air. At 32° F. 100 parts of water dissolve 25·76 parts of the anhydrous salt, and, for every increased degree, 0·8597 parts additional are taken up. The crystals contain 51·22 per cent. of water of crystallization, and dissolve in their own weight of water at 60°, and in three-fourths of their weight at 212°. They melt in their water of crystallization, and at a high temperature fuse into an enamel. (*Berzelius.*) The salt consists of one eq. of acid 40, one of base 20, and seven of water 63 = 123.

Sulphate of magnesia is completely decomposed by potassa, soda, and their carbonates; by lime, baryta, and strontia, and their soluble salts. Ammonia partially decomposes it, and forms with the remainder a double sulphate. The bicarbonates of potassa and soda do not decompose it, except by the aid of heat. "It gives copious white precipitates with chloride of barium, and with a mixed solution of ammonia, chloride of ammonium, and phosphate of soda." *Br.*

Sulphate of magnesia is liable to contain iron and chloride of magnesium, the former of which may be detected by ferrocyanide of potassium, and the latter by its rendering the salt moist. If the addition of sulphuric acid produce no extrication of muriatic acid gas, the fact will prove the absence of chlorides. An aqueous solution of 100 grains of the salt should yield, when completely decomposed by a boiling solution of carbonate of soda, 34 grains of dry carbonate of magnesia, and, according to the British Pharmacopœia, 16·26 grains of the

carbonate after having been well washed, dried, and heated to redness. If the dry precipitate is less, the specimen tested is not all sulphate of magnesia, and probably contains sulphate of soda.

An economical use which has been recommended of sulphate of magnesia is the addition of a strong solution to ordinary whitewash, whereby a beautiful whiteness may be given to walls and ceilings. A little of it, moreover, added to starch considerably increases its stiffening properties, and at the same time in some degree resists the action of fire. (*Chem. News*, April 19, 1867, p. 196.)

Medical Properties and Uses. Sulphate of magnesia is a mild and safe cathartic, operating with little pain or nausea, and producing watery stools. It is more acceptable to the stomach than most medicines of its class, and will often be retained when others are rejected. Like many of the other neutral salts it is refrigerant, and may be made to act as a diuretic by keeping the skin cool, and walking about after it has been taken. It is well adapted to the treatment of fevers and inflammatory affections, especially after a previous thorough evacuation of the bowels by a more energetic cathartic. It is also useful in colic and obstinate constipation, and may be employed in most cases which require the use of a cathartic, without being attended with debility or relaxation of the stomach and bowels. The medium dose is an ounce; but advantage often results from its administration in divided doses, frequently repeated. It is often given in combination with other medicines, especially with senna, the griping effect of which it tends to obviate. The most agreeable form for administering the salt, and that in which it usually agrees best with the stomach, is a solution in carbonic acid water with lemon syrup. By Dr. Henry, of Dublin, it is highly recommended in connection with sulphuric acid. To seven ounces of a saturated aqueous solution of the salt he adds an ounce of the diluted sulphuric acid of the Pharmacopœias, and gives a tablespoonful of the mixture for a dose, in a wineglassful of water.*

MAGNOLIA. *U. S. Secondary.*

Magnolia.

The bark of Magnolia glauca, M. acuminata, and M. tripetala. *U. S.*

Magnolia. *Sex. Syst.* Polyandria Polygynia. — *Nat. Ord.* Magnoliaceæ. *Gen. Ch. Calyx* three-leaved. *Petals* six or more. *Capsules* two-valved, one-seeded, imbricated in a cone. *Seeds* berried, pendulous. *Bigelow.*

The medicinal properties of the Magnolia are common to most, if not all of the species composing this splendid genus. Among the numerous trees which adorn the American landscape, these are most conspicuous for the richness of their foliage, and the magnificence as well as delicious odour of their flowers; and *M. grandiflora* of the Southern States rivals in magnitude the largest inhabitants of our forests. The Pharmacopœia designates *M. glauca*, *M. acuminata*, and *M. tripetala*, each of which we shall briefly describe.

1. *Magnolia glauca.* Willd. *Sp. Plant.* ii. 1266; Bigelow, *Am. Med. Bot.* ii. 67; Barton, *Med. Bot.* i. 77; Michaux, *N. Am. Sylv.* ii. 8. This species of Magnolia, which in the Northern States is often nothing more than a shrub, sometimes attains in the South the height of forty feet. The leaves are scattered, petiolate, oval, obtuse, entire, glabrous, thick, opaque, yellowish-green on their upper surface, and of a beautiful pale glaucous colour beneath. The flowers are large, terminal, solitary, cream-coloured, strongly and gratefully odorous, often scenting the air to a considerable distance. The calyx is composed of three leaves; the petals, from eight to fourteen in number, are obovate, obtuse,

* It is said that a solution of an ounce of the salt in about a pint of water, boiled for three minutes with a grain and a half of tannic acid, or with two or three drachms of roasted coffee, is entirely deprived of bitterness. The liquid prepared with coffee should be strained, and may be sweetened with sugar. (Combes, *Journ. de Pharm.*, 3e sér., xii. 110.)

concave, and contracted at the base; the stamens are very numerous, and inserted on a conical receptacle; the germs are collected into a cone, and each is surmounted by a linear recurved style. The fruit is conical, about an inch in length, consisting of numerous imbricated cells, each containing a single scarlet seed. This escapes through a longitudinal opening in the cell, but remains for some time suspended from the cone by a slender thread.

M. glauca extends along the seaboard of the United States, from Cape Ann, in Massachusetts, to the shores of the Gulf of Mexico. It is abundant in the Middle and Southern States, usually growing in swamps; but is seldom met with in the interior, west of the mountains. It begins to flower in May, June, or July, according to the latitude. It is known by the name of *magnolia* simply in the Northern and Middle States, by that of *white bay* or *sweet bay* in the South, and is occasionally called *swamp sassafras*, *beaver tree*, &c.

2. *M. acuminata.* Willd. *Sp. Plant.* ii. 1257; Michaux, *N. Am. Sylv.* ii. 12. This species is much larger than the preceding, often growing to the height of seventy or eighty feet. The leaves are six or seven inches long, by three or four in breadth, oval, acuminate, and pubescent on their under surface. The flowers are five or six inches in diameter, bluish or cream-coloured, slightly odorous, with obovate rather obtuse petals from six to nine in number. Mingled with the splendid foliage, they give a magnificent aspect to the tree when large and in full bloom. The tree grows in the interior mountainous regions of the United States, extending along the Alleghanies from the State of New York to their termination in Georgia, and seldom existing in the low country far either to the east or west of that range. It is called *cucumber tree*, from the resemblance of its fruit in shape and size to the common cucumber.

3. *M. tripetala.* Willd. *Sp. Plant.* ii. 1258; Michaux, *N. Am. Sylv.* ii. 18. This is a small tree, sometimes though rarely reaching an elevation of thirty feet, and almost always having an inclined trunk. It is remarkable for the size of its leaves and flowers. The former are eighteen or twenty inches long by seven or eight in breadth, thin, obovate, somewhat wedge-shaped, entire, acute at both extremities, pubescent when young, and often disposed in rays at the extremity of the shoots, displaying a surface thirty inches in diameter. Hence has arisen the name of *umbrella tree*, by which this species is distinguished. The flowers are terminal, seven or eight inches in diameter, white, with from five to twelve oval acute petals, of which the three outer are reflexed. This species extends from the northern parts of New York to the southern limits of the United States. It is found only in shady situations, with a strong, deep, and fertile soil.

The leaves of this species are highly recommended by Dr. J. S. Wilson, of Alabama, as a dressing for blisters. He scalds them previously to their application, but presumes that they would answer as well in their natural state. (*South. Med. and Surg. Journ.*, July, 1854.)

The bark and fruit of all the species of Magnolia are possessed of similar medicinal properties; but the bark only is officinal, and that of the root is thought to be most efficient. It has an aromatic odour, and a bitter, pungent, spicy taste. The aromatic property, which resides in a volatile principle, is diminished by desiccation, and entirely lost when the bark is long kept. The bitterness, however, remains. The bark is destitute of astringency. The bark of Magnolia grandiflora, examined by Dr. Stephen Procter, was found to contain volatile oil, resin, and a principle analogous to the liriodendrin of Professor Emmet. (*Am. Journ. of Pharm.*, xiv. 95.)

Medical Properties and Uses. Magnolia is a gently stimulant aromatic tonic and diaphoretic, useful in chronic rheumatism, and capable, if freely given, of arresting the paroxysms of intermittent fever. It has been used advantageously in these complaints, and in remittents, especially of a typhoid character. The dose of the recently dried bark in powder is from half a drachm to a drachm, frequently repeated. The infusion may also be used, but is less efficient. Diluted alcohol extracts all the virtues of the medicine; and a tincture, made by macerating the fresh bark or fruit in brandy, is a popular remedy in chronic rheumatism. W.

MANGANESII OXIDUM NIGRUM. *U.S., Br.*

Black Oxide of Manganese.

Native impure deutoxide of manganese in powder, containing at least 66 per cent. of the pure deutoxide. *U. S.* MnO_2. *Br.*

Manganese, Peroxide of manganese, Deutoxide of manganese, Black oxide of manganese, Pyrolusite; Oxide noir de manganèse, *Fr.;* Braunstein, *Germ.;* Manganese, *Ital., Span.*

The officinal oxide of manganese is the binoxide of a peculiar metal properly called manganese; though this name is commonly applied to the oxide itself. *Metallic manganese* was discovered by Scheele and Gahn in 1774, and is obtained from the native black oxide by intense ignition with charcoal. As obtained by C. Brunner, by decomposing the fluoride by sodium, manganese is brittle, grayish-white, and very hard, being capable of cutting glass, and scratching the best tempered steel. It is susceptible of the most perfect polish, and is not altered, even in moist air, at the ordinary temperature. Its sp. gr. varies from 7·1 to 7·2. (*Chem. Gaz.*, May 1, 1857.) Deville suspects that Brunner's manganese contains a little carbon. This chemist obtained the metal by heating the black oxide in excess with charcoal, in a lime crucible. The metal, thus obtained, is more refractory than iron; while that procured by Brunner fused at the same heat as white cast iron. (*Ibid.*, June 1, 1857.) The eq. number of manganese is 27·7. With oxygen it forms five compounds, three regular oxides and two acids. The *protoxide* is of a light-green colour, and is the oxide present in the salts of manganese. The *sesquioxide* is black or dark-brown, and the *deutoxide* black. The two acids are formed by the action of potassa on the deutoxide, and are called *manganic* and *hypermanganic acids.* Assuming one eq. of manganese in each of these compounds, the protoxide contains one, the sesquioxide one and a half, the deutoxide two, manganic acid three, and hypermanganic acid three and a half equivalents of oxygen. Besides these, there exist a double oxide, of a brownish-red colour, called *red oxide,* consisting of one eq. of protoxide and one of sesquioxide, and invariably formed when any one of the other oxides of manganese is exposed to a white heat; and a native oxide, called *Varvicite,* composed of two eqs. of deutoxide and one of sesquioxide. Metallic manganese is an occasional constituent of organic matter. It has been detected in minute quantity in bone, hair, brain, epidermis, gastric juice, bile, urine, and pus, and has been found by Millon and others in the blood. M. Glénard, of Lyons, denies that it is a normal constituent of the blood, although sometimes present; but the evidence of numerous experimenters shows that it generally exists in that fluid; and, when not detected, it may be because the quantity present is too minute for discovery. According to Mr. E. Davy, caustic potassa, dissolved in an equal weight of water, forms a delicate test for manganese, not obscured by the presence of other metals. The smallest portion of matter, suspected to contain the metal, being finely pulverized or in solution, is placed upon a slip of silver foil, and a drop of the test added. Upon evaporating to dryness with a spirit-lamp, and raising the heat, the characteristic green manganate of potassa will appear on the foil. (*Chem. Gaz.*, March 15, 1854.) Manganese is a constituent of all arable land, and is found in the ashes of most of the vegetables which form the food of man and the inferior animals. In the mineral kingdom, it occurs sometimes as a sulphuret, rarely as a phosphate, but very abundantly as the black or deutoxide, called *pyrolusite.* It is the latter mineral which constitutes the officinal oxide.

Properties. Deutoxide of manganese, as it occurs in nature, is very diversified in its appearance. Its sp. gr. varies from 4·7 to 4·9. It is found sometimes in brilliant needle-shaped crystals, often in compact masses having the metallic lustre, but far more frequently in the form of a dull earthy-looking substance, of a black or brown colour. It is purest when crystallized. As it occurs in commerce, it is usually in the form of a black powder, insoluble in water, and con-

taining more or less oxidized iron, carbonate of lime, sulphate of baryta, and earthy matter. Iron, which is rarely absent, is detected by the production of a greenish or blue tint on the addition of ferrocyanuret of potassium to its muriatic solution. When exposed to a red heat it yields half an equivalent of oxygen, and is reduced to the state of sesquioxide. Hence its use in obtaining that gas. Good samples, after being dried, lose, when heated to whiteness, 12 per cent. of oxygen. It is distinguished from sulphuret of antimony by its infusibility, and by causing the evolution of chlorine on being heated with muriatic acid. When of a brown colour, it is not of good quality.

But few mines of deutoxide of manganese exist; though the metal itself is very generally diffused throughout the mineral kingdom. It occurs most abundantly in Bohemia, Saxony, the Hartz, France, and Great Britain. In the United States no mines have been opened, except in Vermont, from which State an inferior brown ferruginous manganese is supplied through Boston. Besides this source, the mineral is received from Nova Scotia, France, Germany, England, and occasionally Scotland. It comes packed in casks or barrels, generally in lumps and coarse powder, just as it is dug out of the mines; though occasionally it is received from England ready pulverized. It is a good rule to buy it unpowdered; as its quality can be better judged of in that state. A dark shining crystalline appearance may be taken as an indication of good quality. The Nova Scotia manganese is better than the Vermont; but that from Germany, England, and Scotland is the best, and commands the highest price.

Medical Properties and Uses. Deutoxide of manganese is deemed tonic and alterative. When slowly introduced into the system, as happens to those engaged in grinding the mineral, it acts, according to Dr. Coupar, of Glasgow, as a cumulative poison, inducing a disease which begins with a staggering gait, and ends in paraplegia. It has been used in syphilis, chlorosis, scurvy, and various skin diseases, especially itch and porrigo. It has lately been employed, in a purified state, with great advantage by Dr. Arthur Leared, in stomachic pains, of a purely nervous character, such as are apt to come on after eating. He has also found it useful in pyrosis, and other irritable states of the stomach which are purely functional. It has the advantage over the preparations of bismuth, in these cases, that it does not constipate. (*Glasgow Med. Journ.*, Jan. 1865, p. 79.) The dose is from three to twenty grains, three times a day, given in the form of pill. Dr. Leared gave ten grains of the powder three times a day. For external use, an ointment may be made of one or two drachms of the oxide to an ounce of lard. The sulphate is officinal. For a notice of some other compounds of manganese which have been tried as medicines, see *Part* III.

This oxide is used in the arts for obtaining chlorine in the manufacture of bleaching powder, for giving a black glazing to pottery, and for freeing glass from the colour which it derives from iron. In the laboratory, it is employed to obtain oxygen and chlorine, and to form the salts of manganese. In pharmacy it is used for liberating chlorine from muriatic acid and from common salt, and iodine from iodide of sodium, contained in kelp.

MANGANESII SULPHAS. *U. S.*

Sulphate of Manganese.

This salt was first made officinal in the present edition of the U. S. Pharmacopœia, in which it has a place in the Materia Medica list. It may be prepared by heating the native black oxide with concentrated sulphuric acid. Oxygen is evolved, and the sulphate of the protoxide is formed. The product, when exhausted by water, furnishes a solution which must be heated to nearly the boiling point, and treated with carbonate of manganese, added by small portions

at a time, which will precipitate any iron present, and change the colour of the liquid from a dark-red to a pale-rose tint. The liquid is then filtered, evaporated to the consistence of a thin syrup, and set aside to crystallize.*

Properties. Sulphate of manganese consists of one eq. of protoxide of manganese and one of sulphuric acid (MnO,SO_3). From its aqueous solution it crystallizes in rhombic prisms, which contain variable proportions of water of crystallization according to the temperature of the solution and other circumstances. Obtained by evaporation at a gentle heat, they contain four eqs. of water; between 45° and 68°, five eqs.; under 42°, seven eqs.; and a concentrated solution, mixed with sulphuric acid, and evaporated, yields granular crystals with one eq. Heated to 240°, the crystals lose three eqs. of water, and at a red heat become anhydrous. (*Brande and Taylor.*) The crystals usually have a pale-rose or pink colour. The salt has an astringent and bitterish taste. It is very soluble in water; but its solubility varies with its water of crystallization. When anhydrous it is dissolved by two parts of water at 60°, and in its own weight at 212°. It is insoluble in alcohol. If carelessly prepared, it is apt to contain copper and arsenic, as well as iron. As it is the source of nearly all the preparations of manganese, it is of importance that it should be pure. Hence, the sulphate, as first obtained, should be calcined at a low red heat at least twice, to render the contaminating metals insoluble, and then tested in solution, to be sure of its purity. According to M. A. Gorgeu, copper and iron, as well as nickel and cobalt, are completely precipitated by sulphuret of manganese. In applying this reagent, the impure solution is shaken for about a quarter of an hour with the sulphuret, and then boiled for a few minutes. (*Chem. Gaz.*, July 1, 1853, p. 249.) In the description of it in the U. S. Pharmacopœia, the salt is stated not to be precipitated by tincture of nutgall, to give with alkalies a white precipitate soon becoming brown on exposure, and to throw down a flesh-coloured precipitate with hydrosulphate of ammonia, and a white one with ferrocyanide of potassium.

Medical Properties and Uses. C. G. Gmelin found sulphate of manganese to produce an extraordinary secretion of bile when given to the inferior animals, and its effects as a cholagogue have been observed in man. According to the late Dr. Thomas Thomson, of Glasgow, it resembles sulphate of soda both in taste and effect, operating as a purgative in the dose of one or two drachms. From the circumstance that manganese had been found in small proportion in the blood, it was conjectured that this metal, like iron, might play an important part in the human economy; and trial was made of its various preparations in debilitated states of the system, and especially in anæmia, in which the hope was

* The following modification of the process given in the text has been published by Mr. C. Lewis Diehl, Jr., who has obtained by means of it an abundant product of the pure salt. A mixture of 5 parts of peroxide of manganese and 0·75 of coarsely powdered charcoal is exposed to a red heat, in a covered crucible, until all the charcoal is consumed. The contents of the crucible, after cooling, are put into a porcelain dish, and treated with 6·5 parts of sulphuric acid. The whole is then evaporated to dryness, and the residue, being returned to the crucible, is again heated to redness. When cool, the mass is rubbed to powder if necessary, and treated twice with 8 parts of boiling water; and the liquors, having been mixed, are filtered, evaporated till a pellicle appears, and set aside to crystallize. It is important that the liquid should be removed from the sand-bath as soon as the pellicle begins to form; as, if the heat be continued longer, an insoluble sulphate is deposited. If the peroxide of manganese employed is of good quality, a pure sulphate will be obtained; any salt of iron or copper present being rendered insoluble by the heat. (*Am. Journ. of Pharm.*, March, 1867, p. 139.)

Another process, introduced into use by Mr. Laster, Chemist of the Charity Hospital, New Orleans, is highly praised by Dr. A. J. Semmes, visiting physician of the same hospital. The following is the formula. "Take of Binoxide of Manganese 40 parts, Commercial Hydrochloric Acid 200 parts. Dissolve the binoxide in the acid beneath a chimney-flue, and, when solution is complete, and chlorine no longer evolved, mix very gradually 53 parts of sulphuric acid with the reddish liquid; continue the evaporation beneath the flue until acid vapour is no longer driven off, and the mass becomes dry Dissolve this mass in 350 parts of water heated to the boiling point. Treat the solution with carbonate of manganese until it becomes rose-red, filter or decant, evaporate and crystallize." (*Ibid.*, March, 1868, p. 175.)—*Note to the thirteenth edition*

entertained that it might prove a useful adjuvant of the chalybeates as a reconstructive agent. When given with iron, its use was certainly in many instances followed by the most satisfactory results; but it may be questioned whether the beneficial effects were in any respect greater than those which the iron would have produced without such an auxiliary; and, where manganese has been used alone in anemic cases, it has generally failed. Dr. Garrod, of London, has recently reported the result of some trials made with it, in one of the hospitals of that city, in cases of anæmia, the inference from which is altogether unfavourable to manganese as a remedy in that disease. (*Med. Times and Gaz.*, Feb. 1863, p. 222.) Dr. Hammond, of New York, has found the sulphate of manganese successful in two cases of chorea, which had resisted other treatment. (*Med. & Surg. Reporter*, Aug. 1, 1868, p. 87; from *N. Y. Med. Gaz.*) The dose of sulphate of manganese as a tonic is from five to twenty grains. B.

MANNA. *U. S., Br.*

Manna.

The concrete juice, in flakes, of Fraxinus Ornus, and of Fraxinus rotundifolia. *U. S.* A concrete saccharine exudation from the stem of Fraxinus Ornus and F. rotundifolia, obtained by making incisions in the stems. *Br.*

Manne, *Fr.;* Manna, *Germ., Ital.;* Mana, *Span.*

Manna is not the product of one plant exclusively. Besides the two species of Fraxinus indicated by the Pharmacopœias, it is said to be obtained also from several other trees, belonging to the genera *Ornus* and *Fraxinus*, among which *F. excelsior* and *F. parviflora* have been particularly designated. Many saccharine substances, generally exudations from plants, have, from their resemblance to this substance, obtained the name of manna, and attracted more or less attention from writers. They are described in a note.*

* *False Mannas.* Burkhardt states that a species of manna, which exudes from the tamarisk of the north of Africa (*Tamarix Gallica*, Ehrenberg), is used by the Bedouin Arabs near Mount Sinai with their food. This substance, however, according to Mitscherlich, contains no mannite, but consists wholly of mucilaginous sugar. M. Berthelot found a sample of manna from Sinai to consist of 55 per cent. of cane sugar, 25 of *levulose* and glucose, and 20 of dextrin and analogous substances. (*Annales de Chim. et Phys.*, lxvii. 82.) The same chemist obtained from Turkish manna a new variety of sugar, which he named *trehalose*. (*Gaz. Méd. de Paris*, A.D. 1857, no. 49.) The manna used in India is said to be the product of *Hedysarum Alhagi* of Linn., *Alhagi Maurorum* of De Candolle, a thorny shrub which grows abundantly in the deserts of Persia and Arabia. It is much inferior to that obtained from the Ornus. A substance closely resembling manna is procured by exudation from *Eucalyptus mannifera*, growing in New South Wales. It contains a saccharine matter called *melitose*, different from mannite, and from all the varieties of sugar in properties, though isomeric with glucose. It is susceptible of the vinous fermentation. (See *Am. Journ. of Pharm.*, xxviii. 157.) Another manna found in New Holland is produced upon the leaves of *Eucalyptus dumosa*, when very small, and sometimes appears spread over large extents of country like a kind of snow. The natives use it for food. It is a complex body, containing sugar, gum, starch, inulin, and lignin. (*Journ. de Chim. et de Pharm.*, xvi. 240.) It is said to be a secretion from an insect, formed into minute cells, each of which is the abode of one of the insects. It is called *lerp* by the natives. (See *Am. Journ. of Pharm.*, Nov. 1862, p. 547.) The substance known in France by the name of *Briançon manna*, is an exudation from the common European larch (*Larix Europæa* or *Pinus Larix*), and differs chemically from ordinary manna in containing no mannite. Berthelot found in it a peculiar sugar, analogous to that of the cane, which he named *melezitose*. (See *Am. Journ. of Pharm.*, Jan. 1859, p. 61.) *Larix Cedrus*, of Mount Lebanon, yields a similar product, which has some repute in Syria as a remedy in phthisis. (*Pharm. Journ. and Trans.*, xiii. 411.) A substance resembling manna, of a sweet, slightly bitter, and terebinthinate taste, and actively purgative, exudes from incisions in *Pinus Lambertiana*, of Southern Oregon, and is used by the natives. (*Nar. of U. S. Expl. Exped.*, v. 232.) M. Berthelot has extracted from this product a peculiar saccharine principle, which he calls *pinite*. It is very sweet, but does not undergo the vinous fermentation. (See *Am. Journ. of Pharm.*, xxviii. 157.) In the neighbourhood of Diarbekir, in Asiatic Turkey, a saccharine substance, known as Diarbekir manna, is found on the leaves of dwarf oaks, from which it appears to be exuded. (*Ibid.*, Nov. 1862, p. 546.) Certain seaweeds, after their death, become covered, on exposure to

Ornus. *Sex. Syst.* Diandria Monogynia. — *Nat. Ord.* Oleaceæ.

Gen. Ch. Calyx very small, four-cleft. *Corolla* divided to the base into linear segments. *Pericarp* a winged key not dehiscing. *Lindley.*

This genus was separated by Persoon from the Fraxinus of Linnæus.

Ornus Europæa. Persoon, *Synops.* i. 9; Lindley, *Flor. Med.* 547; Carson, *Illust. of Med. Bot.* ii. 8, pl. 61. — *Fraxinus Ornus.* Willd. *Sp. Plant.* iv. 1104. Woodv. *Med. Bot.* p. 589, t. 209. The *flowering ash** is a tree of moderate height, usually from twenty to twenty-five feet, very branching, with opposite, petiolate, pinnate leaves, composed of three or four pairs of leaflets, and an odd one at the end. The leaflets are oval, acuminate, obtusely serrate, about an inch and a half in length, smooth, of a bright-green colour, and supported on short footstalks. The flowers are white, and usually expand with the leaves. They grow in close panicles at the extremity of the young branches, and have a very short calyx with four teeth, and four linear lanceolate petals.

Both this species of *Ornus* and *O. rotundifolia* are natives of Sicily, Calabria, and Apulia; and both contribute to supply the manna of commerce. The former is cultivated in Sicily, yields manna after the eighth year, and continues to yield it for ten or twelve years, when it is usually cut down, and young sprouts allowed to grow up from the root. (Stettner, *Archiv. der Pharm.*, liii. 194.) During the hot months the juice exudes spontaneously from the bark, and concretes upon its surface; but, as the exudation is slow, it is customary to facilitate the process by making deep longitudinal incisions on one side of the trunk. In the following season these are repeated on the other side, and thus alternately for the whole period during which the trees yield manna, extending sometimes, it is said, to thirty or even forty years. Straw or chips are frequently placed so as to receive the juice, which concretes upon them. The manna varies in its character according to the mode of collection, nature of the season, and period of the year in which the exudation takes place. That procured in Sicily is said to be the best. Three varieties are distinguishable in commerce.

1. The purest is that named *flake manna*, or *manna cannulata*. It exudes spontaneously, or by incisions, during the hottest and dryest weather in July and August. According to Stettner, it is furnished by the upper incisions upon the trunk; while the lower incisions yield the inferior varieties. It is in irregular, unequal pieces, often several inches long, resembling stalactites, rough, light, porous, brittle, whitish or yellowish-white, and frequently concave on the surface by which they were attached to the trunk, and which is often soiled by impurities, sometimes by adherent fragments of the bark. When broken, these pieces exhibit a crystalline or granular structure. This variety is sometimes in small fragments, generally less than an inch in length.

2. *Common manna—manne en sorte* of French pharmacy—is next in quality, and is collected in September and the beginning of October, when the heat of the weather has begun to moderate. The juice does not now concrete so readily, and a portion, falling on the ground at the root of the tree, becomes more or less mixed with impurities, and forms imperfectly solid masses, which require to be further dried in the sun. Common manna consists of whitish or yellowish fragments, similar to the pieces of flake manna, but much smaller, mixed with a soft, viscid, uncrystallized brownish matter, identical with that which constitutes the following variety.

3. *Fat manna* is collected in the latter part of October and November, when the weather is cooler and rains more common. The juice is now still less disposed to concrete, and flowing down the trunk is received in a small excavation at its base. As found in commerce, it is in the form of a soft, viscous mass,

the air, with an efflorescence of mannite, supposed not to pre-exist in the plant, but to be formed at the expense of their mucilaginous matter. (*Journ. de Pharm.*, Avril, 1859, p. 314.)

* A syrup prepared from the inner bark of this tree has been employed, in Europe, by Dr. Devergie, with supposed advantage, in chronic eczema and impetigo. The bark contains much tannin, and a mucilaginous principle, which renders diluted alcohol a better menstruum than boiling water. (*Journ. de Pharm.*, 3e sér., ix. 347.)

containing few crystalline fragments, of a brown or yellowish-brown colour, and full of impurities.

Manna may be found in the shops, of every grade, from the most impure of the third variety to the purest of the first; but the worst kind is not often imported into this country.

Attempts have sometimes been made to counterfeit manna; but the facility of detection renders frauds of this kind unprofitable, and they are not often practised. Dr. R. P. Thomas has described, in the *Am. Journ. of Pharm* (xxiv. 208), a sophisticated drug, which was brought into our markets under the name of manna, but differed from the genuine drug both in sensible and chemical properties, not even containing mannite. Baumé describes a method in which common manna is purified so as to resemble flake manna. It consists in dissolving common manna in a little water, allowing the liquid to settle, decanting it in order to separate the impurities, then inspissating it so that it will congeal on cooling, and immersing threads in the inspissated liquid, several times successively, in the manner practised by candle-makers. It may be still further purified by the use of animal charcoal. Thus prepared it contains less mannite than flake manna, and less of the nauseous principle; but is said not to operate less effectively as a laxative.

Properties. Manna has a slight, peculiar odour, and a sweet taste, which in the impure kinds is also very nauseous, but, in the finest flake manna, scarcely so much so as to be disagreeable. It melts with heat, and takes fire, burning with a blue flame. When pure it is soluble in three parts of cold, and in its own weight of boiling water. From a boiling saturated aqueous solution, it separates in partially crystalline masses on cooling. Alcohol also dissolves it, and, if saturated by means of heat, deposits upon cooling a large proportion of the manna in a beautifully crystalline form. Fourcroy and Vauquelin found manna to consist of, 1. a peculiar sweet principle, called mannite, which constitutes 75 per cent.; 2. true sugar; 3. a yellow nauseous matter, upon which the purgative property is thought chiefly to depend; and 4. a little mucilage. Leuchtweiss obtained from 105 parts of manna 11·6 of water, 0·4 of insoluble matter, 9·1 of sugar, 42·6 of mannite, 40·0 of a mixture of mucilaginous matter containing mannite, resin, organic acid, and a nitrogenous substance, and 1·3 of ashes. Manna has recently been examined chemically by M. Buignet, who discovered in it, what had never before been detected, a considerable proportion of dextrin. He appears to have been led to this discovery by observing a very energetic right rotatory power in flake manna, which could not be owing to the saccharine matter it contained, because the same power continued after all the sugar had been destroyed by fermentation. Dextrin forms about one-fifth part of flake manna, and a much larger part of the inferior kinds. It may be readily obtained separate by triturating 200 parts of flake manna with 400 of alcohol of 70° in successive portions, filtering the resulting mixture, by which the mannite is left behind, and then separating the sugar and dextrin contained in the clear liquor. This is done by concentrating the liquor to a syrupy consistence, and adding about 10 parts of alcohol at 90°. The mixture separates into two layers, the upper consisting of a strong alcoholic solution of sugar, the lower of a saturated solution of dextrin in weak alcohol. The latter is separated, washed repeatedly with alcohol at 90°, and then, after dilution with water, decolorization, and filtration, is evaporated gently by a water-bath till it ceases to lose weight. The substance remaining is dextrin. The saccharine matter of manna is a mixture of cane sugar and inverse or uncrystallizable sugar, which are in such proportion as almost to neutralize their reciprocal optic properties. All the forms of commercial manna contain both sugar and dextrin, and, though the quantity of the two jointly varies considerably, yet their relative proportion is invariable, being 2 eqs. of dextrin and 1 eq. of sugar. This is the same result which takes place in the saccharification of starch; and the inference is fair, that the dextrin and sugar in manna are the result of a transformation of starch in the plant. (*Journ. de Pharm. et de Chim.*, Juillet, 1868, pp. 5–16.)

It is owing to the presence of true sugar and dextrin that manna is capable of fermenting. *Mannite* is white, inodorous, crystallizable in semi-transparent needles, of a sweetish taste, soluble in five parts of cold water, scarcely soluble in cold alcohol, but readily dissolved by that liquid when hot, and deposited when it cools. Its composition is $C_{12}H_{14}O_{12}$. Unlike sugar, it does not undergo the vinous fermentation; but, if mixed with chalk and cream cheese, and kept for some weeks at the temperature of 104° F., it yields alcohol largely, with the disengagement of carbonic acid and hydrogen, and the production of lactic acid. No fungus is produced, as in the ordinary fermentation of sugar. (Berthelot, *Journ. de Pharm.*, xxx. 269.) With lime, baryta, and strontia, it forms definite compounds, soluble in water, and precipitable from their aqueous solutions by alcohol. (*Ibid.*, Jan. 1860, p. 56.) It does not reduce an alkaline solution of oxide of copper; and a test of its purity is thus presented. (*Am. Journ. of Pharm.*, Jan, 1861, p. 26.) It may be obtained by boiling manna in alcohol, allowing the solution to cool, and redissolving the crystalline precipitate. Pure mannite is now deposited. Another method is to dissolve flake manna in water, precipitate by solution of subacetate of lead, filter, throw down the excess of lead by sulphuric acid, evaporate the solution, and mix with alcohol. On cooling, the mannite is deposited. (Bonsall, *Arch der Pharm.*, cxxxiv. 70.) This principle has been found in numerous vegetables. It is said to be gently laxative in the dose of one or two ounces.

Manna, when long kept, acquires a deeper colour, softens, and ultimately deliquesces into a liquid, which, on the addition of yeast, undergoes the vinous fermentation. This is probably owing to its conversion into sugar by the absorption of enough oxygen to neutralize the slight excess of hydrogen, which constitutes the only essential difference in composition between it and proper sugar. That which is dryest resists this change the longest. It is said that manna, recently gathered, is less purgative than it afterwards becomes.

Medical Properties and Uses. Manna is a gentle laxative, usually operating mildly, but in some cases producing flatulence and pain. Though peculiarly adapted to children and pregnant women, it may be given with advantage in ordinary cases of piles from constipation, unattended with dyspeptic symptoms. It is usually, however, prescribed with other purgatives, particularly senna, rhubarb, magnesia, and the neutral salts, the taste of which it conceals, while it adds to the purgative effect.

The dose for an adult is from one to two ounces; for children, from one to four drachms. It is usually given dissolved in water or some aromatic infusion; but the best flake manna may be administered in substance. W.

MARANTA. *U. S.*

Arrow-root.

The fecula of the rhizoma of Maranta arundinacea. *U. S.*

Arrow-root, *Fr.;* Amerikanisches Stärkmehl, Arrowmehl, *Germ.*

Maranta. *Sex. Syst.* Monandria Monogynia. — *Nat. Ord.* Marantaceæ.

Gen. Ch. Anther attached to the petal-like filament. *Style* petal-shaped. *Stigma* three-sided. *Flowers* panicled. *Loudon's Encyc.*

Maranta arundinacea. Willd *Sp. Plant.* i. 13; Carson, *Illust. of Med. Bot.* ii. 53, pl. 97. The root (rhizoma) of this plant is perennial, tuberous, fleshy, horizontal, nearly cylindrical, scaly, from six inches to a foot or more in length, and furnished with numerous long white fibres. It sends forth several tuberous, jointed, curved, white, scaly stoles, the points of which sometimes rise above the ground, and become new plants. The stems, of which several proceed from the same root, are annual, slender, branched, jointed, leafy, and about three feet in height. The leaves are ovate-lanceolate, about four inches long, alternate, and supported solitarily, at the joints of the stem, upon long, sheathing footstalks. The flowers are in a long, loose, spreading, terminal panicle, at each ramification of which is a solitary linear bracte. The calyx consists of three small lanceolate

leaves. The corolla is white and monopetalous, with a tube longer than the calyx, and a double border, of which the three outermost segments are smallest, and the two inner obovate, and slightly emarginate.

The arrow-root plant is a native of the West Indies, where it is largely cultivated. It is cultivated also in the East Indies, Sierra Leone, the south of Africa, and our Southern States, especially Georgia and Florida. The plant is easily propagated by cuttings of the root. The fecula is prepared in the following manner. The roots are dug up when a year old, washed, and then beaten into a pulp, which is thrown into water, and agitated so as to separate the amylaceous from the fibrous portion. The fibres are removed by the hand, and the starch remains suspended in the water, to which it gives a milky colour. The milky fluid is strained through coarse linen, and allowed to stand that the fecula may subside, which is then washed with a fresh portion of water, and afterwards dried in the sun. We obtain the officinal arrow-root from the West Indies, and the Southern Atlantic States. That from the Bermudas has in general been most highly esteemed.*

Other plants contribute to furnish the arrow-root of commerce. Lindley states that it is procured in the West Indies from *Maranta Allouya* and *M. nobilis*, besides *M. arundinacea*. Under the name of *M. Indica*, Tussac describes a distinct species, which he says was originally brought from the East Indies, and is now cultivated in Jamaica. This, however, is generally considered as a mere variety of M. arundinacea, from which it differs chiefly in having leaves more elongated at the point, and smooth on both sides. Very fine arrow-root is obtained in the East Indies from the root of *Curcuma angustifolia* of Roxburgh, which is cultivated in Travancore. But the product is lighter than the Maranta arrow-root, and does not so quickly make a jelly. Ainslie states that *M. arundinacea* has been introduced from the West Indies into Ceylon, where good arrow-root is prepared from it. A fecula, closely resembling that of the Maranta, is said by Guibourt to be prepared in the West Indies from the root of the cassava plant (*Janipha Manihot*); and it is not improbable that a variety of arrow-root brought to this country from Brazil has a similar origin. In fact, it often contains small lumps, as large as a pin's head, identical with tapioca, which is a product of *J. Manihot*. A variety of arrow-root has been imported from the Sandwich Islands. Mr. Nuttall, during a visit to these islands, found that it was obtained from a species of Tacca, which he described by the name of *Tacca oceanica*. (*Am. Journ. of Pharm.*, ix. 305.) It is said that a similar product is afforded by *Tacca pinnatifida*, growing in the East India province of Arracan. (*Pharm. Journ.*, vi. 383.) Arrow-root has been brought from Florida, prepared near St. Augustine from the root of *Zamia integrifolia*, by a process similar to that employed for the fecula of the Maranta (Dr. J. Carson, *Am. Journ. of Pharm.*, xiv. 22); but care must be taken not to confound this with the genuine maranta from the same State. The tuberous roots of different species of Alstrœmeria, growing in S. America, yield a fecula, used for the same purposes as the maranta; and a specimen, under the name of *Talcahuana arrow root*, was sent from Chili by Dr. Ruschenberger to Prof. Carson, of this city, who ascertained it to be the product of the *Alstrœmeria ligtu*. (*Ibid.*, xxxii. 289.) In the West Indies, substitutes for arrow-root are furnished by the roots of *Dioscorea sativa* or *yam*, and of *Colocasia esculenta*, and by the fruit of *Artocarpus incisa* or bread-fruit tree.† Attempts have been made to substitute finely prepared potato starch for arrow-root; and there is no doubt that in nutritive properties it is quite equal; but patients complain of an unpleasant taste of the potato which it is apt to retain.

* For an account of the cultivation of the plant and the preparation of the fecula in Georgia, see a report by Mr. Robert M. Battey, of Rome, Georgia, on Maranta arundinacea, in the *Proceedings of the Am. Pharm. Association*, A.D. 1858, p. 332. (*Note to the twelfth edition.*)

† Specimens of these feculas were seen by the author in the *Palais d'Industrie* of Paris among the French colonial products, in the autumn of 1860.

Arrow-root is in the form of a light white powder, or of small pulverulent masses, without smell or taste. It has a firm feel when pressed between the fingers, and produces a faint crackling sound when rubbed. It is a pure starch, corresponding in chemical properties with that of wheat and the potato. It is very apt to be musty, and should then be rejected. The odour and taste are the best criteria of its purity. It should be perfectly free from smell and unpleasant flavour. Prof. Procter has rendered musty arrow-root sweet and fit for use by washing it thoroughly with two successive portions of cold water, and then drying it upon frames of muslin in a warm place. (*Am. Journ. of Pharm.*, xiii. 188.) Arrow-root is said to be sometimes adulterated with common starch, and that of the potato. These may be detected by the aid of the microscope. Muriatic acid has been proposed as a test. A mixture of equal parts of that acid and of water, rubbed with about half its weight of potato or wheat starch, very quickly forms so thick a mucilage that the mortar in which the trituration is effected may be raised by the pestle; while the same result does not take place with rice flour or arrow-root under 25 or 30 minutes. So small a proportion as from 4 to 6 per cent. of the impurity may, it is asserted, be detected in this way. (*Journ. de Pharm.*, 3e sér., ii. 246.)

As the microscope offers the best means of distinguishing the different varieties of fecula sold as arrow-root, or used for its adulteration, it is proper to indicate the form of their granules as exhibited by this instrument. Those of the proper officinal or *Maranta arrow-root* are rarely oblong, somewhat ovate-oblong, or irregularly convex, with very fine rings, a circular hilum which cracks in a linear or stellate manner, and small mammillary processes occasionally projecting from them. (*Pereira.*) The largest are the 750th of an inch, but many not more than the 2000th of an inch long; and their breadth is generally two-thirds of their length. (*Christison.*) The granules of the *East India arrow-root* are, according to Pereira, of unequal size, ovate or oblong-ovate, flattened, and often furnished with a very short neck or nipple-like projection. The rings are numerous, close, and very fine; and the hilum, which is situated at the narrow extremity, is circular, small, and indistinct. The microscopic appearance of the *tapioca fecula* will be described under the head of *Tapioca.* The *Tacca fecula* from the South Sea Islands, examined by Pereira, consisted of circular, muller-shaped, or polyhedral granules, with few and not very distinct rings, and a small, circular hilum, which cracked in a linear or stellate manner. The *Florida* or *Zamia arrow-root* was found by Dr. Carson to consist of granules forming the half, third, or quarter of a solid sphere. The *potato starch* granules are of various shape and size, but generally ovate or elliptical, and from the 7000th to the 300th of an inch in length; the largest being inferior in size only to the largest of the canna starch or *tous-les-mois.* (See *Canna.*) They are strongly marked with concentric rings, and have a circular hilum, from which usually proceed the cracks observable in some of the larger grains. (*Pereira.*)

Medical Properties and Uses. Arrow-root is nutritious and demulcent, affording a light, very mild, and easily digested article of diet, well adapted for the sick and convalescent, and peculiarly suited, from its demulcent properties, to bowel complaints and diseases of the urinary passages. It is much used as food for infants after weaning, or when the mother's milk is insufficient. It is prepared by dissolving it in hot water, with which it forms a pearly gelatinous solution, and, if in sufficient quantity, a jelly-like mass on cooling. A tablespoonful will communicate sufficient consistence to a pint of water. It should first be formed into a paste with a little cold water, and the boiling water then gradually added with brisk agitation. The preparation may be rendered more palatable by lemon-juice and sugar, or in low forms of disease by wine and spices. For children, arrow-root is usually prepared with milk.

MARMOR. *U. S.*

Marble.

White granular carbonate of lime. *U. S.*

Off. Syn. MARMOR ALBUM. *White Marble.* CaO,CO_2. Hard white crystalline native carbonate of lime, in masses. *Br.*

White Marble; Marbre, *Fr.;* Marmor, *Germ.;* Marmo, *Ital.;* Marmol, *Span.*

Marble is used for obtaining carbonic acid, and for making several officinal preparations. For the former purpose common marble is sufficiently pure; for the latter, the purer varieties must be selected.

The officinal marble is a white granular substance, having a sp. gr. varying from 2·7 to 2·8. It is brittle, pulverizable, and insoluble in water. It is wholly dissolved by dilute muriatic acid with effervescence. If magnesia be present, the neutral muriatic solution will be precipitated by ammonia; and if baryta or strontia be an impurity, a similar effect will be produced by a solution of sulphate of lime. When marble is exposed to a full red heat, it loses about 44 per cent. of carbonic acid, and is converted into lime. (See *Calx.*) In composition it agrees with chalk.

The purest kind of marble is that of *Carrara*, sometimes called *statuary marble;* but it is not necessary that this kind should be obtained for pharmaceutic operations. Marble, sufficiently pure for these purposes, is found in various parts of the United States. It is necessary, however, to reject the *dolomitic marbles*, which contain a considerable proportion of magnesia.

Marble is used, in pharmacy, chiefly for furnishing carbonic acid gas.

MARRUBIUM. *U. S.*

Horehound.

The herb of Marrubium vulgare. *U. S.*

Marrube blanc, *Fr.;* Weisser Andorn, *Germ.;* Marrubio, *Ital., Span.*

MARRUBIUM. *Sex. Syst.* Didynamia Gymnospermia. — *Nat. Ord.* Lamiaceæ or Labiatæ.

Gen. Ch. Calyx salver-shaped, rigid, ten-streaked. *Corolla* with the upper lip bifid, linear, and straight.

Marrubium vulgare. Willd. *Sp. Plant.* iii. 111; Woodv. *Med. Bot.* p. 332, t. 118. *White horehound* has a perennial fibrous root, and numerous annual stems, which are quadrangular, erect, very downy, and from twelve to eighteen inches high. The leaves are roundish-ovate, dentate or deeply serrate, wrinkled, veined, hoary on the under surface, and supported in pairs on strong footstalks. The flowers are white, and in crowded axillary whorls. The calyx is tubular, and divided at the margin into ten narrow segments, which are hooked at the end. The corolla is also tubular, with a labiate margin, of which the upper lip is bifid, the under reflected and three-cleft, with the middle segment broad and slightly scalloped. The seeds are four, in the bottom of the calyx. The plant is a native of Europe, but has been naturalized in this country, where it grows on the roadsides, and flowers in July and August.

The herb has a strong rather agreeable odour, which is diminished by drying, and lost by keeping. Its taste is bitter and durable. The bitterness is extracted by water and alcohol. It contains a volatile oil, bitter extractive, resin, tannin, and lignin.

Medical Properties and Uses. Horehound is tonic, in large doses laxative, and may be so given as to increase the secretion from the skin, and occasionally from the kidneys. It was formerly considered a valuable deobstruent, and recommended in chronic hepatitis, jaundice, amenorrhœa, phthisis, and various

cachectic affections. By its gently tonic powers it may have proved advantageous in some of these complaints; but it exerts no specific influence over any, and has passed mainly from the hands of physicians into domestic use. It is employed chiefly in catarrh, and other chronic affections of the lungs attended with cough and copious expectoration. The infusion made in the proportion of an ounce of the herb to a pint of boiling water may be given in wineglassful doses. The dose of the powder is from thirty grains to a drachm. The medicine is also much used in the shape of syrup and candy. W.

MASTICHE. *U. S., Br.*

Mastic.

The concrete juice of Pistacia Lentiscus. *U. S.* A resinous exudation obtained by incision from the stem. *Br.*

Mastic, *Fr.;* Mastix, *Germ.;* Mastice, *Ital.;* Almastiga, *Span.;* Sakes, *Turk.;* Arah, *Arab.*

Pistacia. *Sex. Syst.* Dœcia Pentandria. — *Nat. Ord.* Anacardiaceæ.

Gen. Ch. Male. *Calyx* five-cleft. *Corolla* none. Female. *Calyx* three-cleft. *Corolla* none. *Styles* three. *Drupe* one-seeded. *Willd.*

Pistacia Lentiscus. Willd. *Sp. Plant.* iv. 753; Woodv. *Med. Bot.* p. 26, t. 11. The *lentisk* is a shrub or small tree, seldom more than twelve feet in height, much branched towards the top, and furnished with petiolate, abruptly pinnate leaves. The leaflets are from eight to twelve, and usually alternate, with the exception of the two upper, which are opposite. They are ovate-lanceolate, entire, obtuse, often mucronate, and sessile upon the common footstalk, which has a narrow foliaceous expansion on each side. The flowers are dicœcious, and very small. The male are in an axillary ament; the female are arranged alternately upon a common peduncle, which is also axillary. The tree is a native of the countries bordering upon the Mediterranean. The fruit yields by expression a fixed oil, of a deep-green colour, and liquid at about 90° F., which the Arabs of North Africa use both as an article of diet and for light. A resinous exudation from the stem and branches is the officinal part, but it does not appear to be collected in all places where the tree flourishes.

Mastic is obtained chiefly from the island of Scio or Chios, in the Grecian Archipelago, where the tree is cultivated for this product. Incisions are made in the trunk and principal branches, from which the juice slowly exudes, and either hardens in tears upon the bark, or drops on the ground, where it is received upon cloths, or the bare earth, and concretes in irregular masses. The tears are most esteemed. They are of various sizes, oval or roundish, often compressed, smooth, semi-transparent, of a pale-yellow colour, of a shining fracture, friable, and usually covered with a whitish powder, occasioned by their friction against each other. The masses consist of yellowish agglutinated tears, with others of a darker colour and less translucent, and often fragments of wood, bark, or earthy matter intermingled.

Mastic is nearly inodorous, unless rubbed or heated, when it becomes fragrant. Its taste is weak but agreeably terebinthinate, and, after long chewing, very slightly acrid. It is at first friable under the teeth, but soon becomes soft and ductile, and acquires a white opaque appearance. Its sp. gr. is 1·074. It is fusible and inflammable by heat. Alcohol dissolves about four-fifths of it, leaving a viscid substance which becomes brittle when dried, and for which the name of *masticin* has been proposed. This substance, though not dissolved by alcohol, softens and swells up in it, as gluten does in water. According to Berzelius, it possesses the same general properties as copal, and should be considered as a variety of resin. Mastic is wholly soluble in ether, chloroform, and oil of turpentine, scarcely soluble in the fixed oils, and insoluble in water. It consists chiefly of resin, with *masticin*, and a minute proportion of volatile oil, which can scarcely be said to have been obtained in a separate state, though it imparts flavour to alcohol and water distilled from the mastic, especially when this has been previously triturated with an equal weight of carbonate of potassa.

Mastic is occasionally adulterated with olibanum, sandarach, and other resinous bodies; and, in seasons of scarcity, with sea-salt.

Medical Properties and Uses. Mastic was formerly thought to possess properties analogous to those of the turpentines, and was used in debility of the stomach, hæmoptysis from ulceration, leucorrhœa, chronic diarrhœa, &c.; but its virtues were overrated, and it is at present scarcely ever given internally. In the East, however, an aqueous infusion is said to be still used in infantile cholera; and the Greeks employ cataplasms made by mixing it with bread and red wine, which they apply to the lower abdomen. (*Landerer.*) It is sometimes employed to fill the cavities of carious teeth, for which purpose it is well fitted by its softness. Great quantities of it are consumed in Turkey, where it is habitually chewed by the women, under the impression that it sweetens the breath, and preserves the gums and teeth. The alcoholic solution has been employed as a styptic in bleeding from the nose, leech-bites, &c., being applied by means of a camel's-hair pencil directly to the bleeding vessel. Dissolved in alcohol or oil of turpentine, it forms a brilliant varnish. A solution made by macerating half an ounce of mastic and fifteen grains of caoutchouc in two fluidounces of chloroform, and filtering in close vessels, forms a varnish highly esteemed by some microscopists.

The following mode of applying it to carious teeth has been recommended. Dissolve four parts of mastic in one of ether, in a bottle well stopped. With the solution thus formed, which is yellow and of an oily consistence, saturate a small piece of cotton of the size of the carious cavity, and, having well cleansed and dried the cavity, introduce the cotton, without painful pressure, so as to fill it exactly. The resin attaches itself to the diseased surface of the tooth, which it protects from the air, and from the food taken into the mouth.

Off. Prep. Pilulæ Aloës et Mastiches, *U. S.* W.

MATICO. *U. S.*

Matico.

The leaves of Artanthe elongata. *U. S.*

Off. Syn. MATICÆ FOLIA. *Matico Leaves.* The dried leaves of Artanthe elongata. *Br.*

ARTANTHE. *Sex. Syst.* Diandria Trigynia. — *Nat. Ord.* Piperaceæ.

Gen. Ch. *Spikes* solitary, opposite the leaves. *Flowers* hermaphrodite. *Style* none. *Bractes* peltate or cucullate. *Miquel.*

This genus, separated by Miquel from Piper, is very extensive, embracing nearly a hundred species diffused through South and Central America. At least two of these have contributed to furnish their products to commerce; but it is to the A. elongata exclusively that the medicine called matico has been officinally ascribed.*

* *Ava. Kava.* The root of another species of the old genus Piper, *P. methysticum* (*Macropiper methysticum*, Miquel), is used in the Sandwich Islands to form an intoxicating drink, under the name of *ava*, *kava*, or *kawa*. See an article by Mr. Morson in the *Pharm. Journ. and Trans.* (iii. 472), where the plant is figured. M. Gobley has discovered in this root a crystalline principle analogous to piperin which he calls *methysticin*, and which, possessing neither odour nor taste, is probably inert. He found also a greenish-yellow resin, of a strong aromatic smell, and an acrid pungent taste, to which he ascribes the powers of the root. (*Journ. de Pharm.*, Janv. 1860, p. 20.) The priority of this discovery having been disputed by M. Cuzent, the question was referred by the Society of Pharmacy of Paris to a committee, who, after investigating the subject, ascertained that the priority of the discovery was in fact due to Mr. Morson of London, who had announced the discovery so early as 1844; though both the other chemists were ignorant of this fact. The name of *kawine* has been proposed for the acrid resin supposed to be the active principle of the kava. The root contains also a volatile oil, which probably participates with the resin in its effects. (*Ibid.*, Mars, 1862, p. 215.) It is said to be an excellent remedy in gonorrhœa (*Ann. de Thérap.*, 1857, p. 61); and a tincture of it has been recently strongly recommended by Dr. E. W. Pritchard, used internally and locally as a remedy in gout. (*Med. Times and Gaz.*, Dec. 1854, p. 591.)

Artanthe elongata. Miquel; Lindley, *Med. and Œconom. Bot.* p. 133, fig. 195. — *Piper angustifolium.* Ruiz and Pavon, *Flor. Peruv.* — *Piper elongatum.* Vahl. This is a shrub with a jointed stem about twelve feet in height. In a dried specimen received from Dr. Ruschenberger, of the U. S. Navy, the leaves are sessile or very shortly petiolate, oval-lanceolate, acuminate, two or three inches long by about an inch in breadth, bright-green on the upper surface, paler and downy beneath, crenate, minutely and strongly reticulated, of an agreeable aromatic odour, and a strong spicy taste. The spikes are solitary, opposite the leaves, and cylindrical. The bractes are peltate or cucullate; the flowers hermaphrodite. The plant is a native of Peru.

The leaves, spikes, and stalks are mixed together, and more or less compressed, in the packages of the imported drug; and are all possessed of activity, though the leaves only are recognised by the Pharmacopœias. Their shape and general aspect have been described above, as well as their smell and taste. They are readily pulverized, forming a light, greenish, absorbent powder. According to Dr. Hodges, they contain chlorophyll, a soft dark-green resin, brown and yellow colouring matters, gum, salts, lignin, a light-green, thickish volatile oil, and a peculiar bitter principle, soluble in water and alcohol, but not in ether, which he calls *maticin.* (*Philos. Mag.*, Sept. 1844, p. 206.) According to Mr. Wiegand, the maticin of Dr. Hodges is a salt of potassa. Mr. John J. Stell, who examined the drug in the expectation of discovering a principle analogous to cubebin or piperin, failed in the attempt. He found, however, the resin to be very acrid and pungent, and reasonably inferred that the virtues of matico reside in it and the volatile oil. (*Am Journ. of Pharm.*, Sept. 1858, p. 392.)

Medical Properties and Uses. Matico is an agreeable aromatic tonic and stimulant, having a tendency, like cubebs, to act on the urinary passages. It has long been known as a medicine in Peru. Dr. Martius speaks of its use by the natives externally as a vulnerary, and internally as aphrodisiac (*Pharm. Cent. Blatt*, 1843, p. 12); and, according to Dr. Scrivener, who practised medicine at Lima, it is much employed in Peru locally for arresting hemorrhage, and in the treatment of ulcers. (*Am. Journ. of Pharm.*, xviii. 175.) In 1839 it was taken to England, and was prescribed by Dr. Jeffreys, of Liverpool, with advantage, in diseases of the mucous membranes; as gonorrhœa, leucorrhœa, menorrhagia, catarrh of the bladder, hemorrhoids, and epistaxis. Others have employed it with benefit in similar cases and in diarrhœa; and it is said to have proved useful in hæmoptysis, hæmatemesis, dysentery, and hæmaturia. Dr. Ruschenberger gives strong testimony in its favour in several of the diseases mentioned. Its most useful internal application is probably as an alterative stimulant to the diseased mucous membranes. If efficient as a hæmostatic, it must be on principles similar to those upon which oil of turpentine acts; for it is not astringent. As a local styptic it probably acts mechanically in the same manner as agaric. The dose of the powder is from half a drachm to two drachms three times a day. The infusion and tincture are officinal.

Prof. Bentley, of London, describes a new variety of matico, brought from a port of Central America, consisting of broken leaves, spikes, and branches, which he referred to another species of the same genus, *Artanthe adunca*, growing in the W. Indies and various parts of S. America. The medicine is distinguishable from the genuine, by the want of the reticulated upper surface and downy under surface which characterize the latter. Prof. Bentley found the sensible properties of the new variety very similar to the old, and assumes that in medicinal virtues the two are nearly identical. (*Pharm. Journ.*, Jan. 1864, p. 290.)

MATRICARIA. *U. S.*

German Chamomile.

The flowers of Matricaria Chamomilla. *U. S.*

Matricaria. *Sex. Syst.* Syngenesia Superflua. — *Nat. Ord.* Compositæ-Senecionideæ, *De Cand.* Asteraceæ, *Lindley.*

Gen. Ch. Calyx flat, imbricate, with scales having scarious margins. *Receptacle* naked, terete. *Pappus* none.

Matricaria Chamomilla. Linn. *Sp.* 1256. This is an annual plant, with a branching stem a foot or two in height, bearing alternate leaves about two inches long, the lower ones tripinnate, the upper bipinnate or simply pinnate, and all of them very green, and nearly or quite smooth. The leaflets are linear and very small. The flowers appear singly at the ends of the stem and branches. They are about three-quarters of an inch in diameter, with the ray spreading. The scales of the calyx are obtuse, green in the middle, and whitish, membranous, and translucent at the margin. The ray florets are white, at first spreading, and ultimately reflected. The disk is of a deep-yellow colour, at first flat, but in the end convex, and even somewhat conical.

The plant is a native of Europe, and is occasionally cultivated in our gardens. All parts of it are active; but the flowers only are officinal. These shrink in drying, so that they are scarcely half as large as in their recent state. Those found in our shops are imported from Germany.

The dried flowers of the Matricaria are considerably smaller than common chamomile, and exhibit a larger proportion of the disk florets compared with those of the ray. They have a strong, peculiar, rather unpleasant odour, and a disagreeable bitter taste. Their active constituents are volatile oil and bitter extractive, which are readily taken up by water and alcohol. The oil, which is obtained by distillation with water, is thick, somewhat tenacious, of a fine deep-blue colour becoming brown by age, and almost opaque in mass. Though supposed by Gerhardt to be identical with the oil of the proper chamomile (Anthemis nobilis), it has been shown to be distinct. (*Pharm. Journ.*, Feb. 1862, p. 429.) It congeals at —4° F. Diluted muriatic and nitric acids render it green, concentrated sulphuric acid reddish-yellow, chlorine yellowish-white and tenacious, iodine reddish-brown and thick, and bromine brown and elastic. (See *Am. Journ. of Pharm.*, March, 1864, p. 109.)

Medical Properties and Uses. Matricaria is a mild tonic, very similar to chamomile in medical properties, and, like it, capable, in large doses, of producing an emetic effect. It is esteemed also in Europe antispasmodic and anthelmintic. It is much employed in Germany; but in this country scarcely at all, unless by German practitioners. It may be given for the same purposes and in the same manner as chamomile. W.

MEL. *U. S., Br.*

Honey.

A liquid prepared by Apis mellifica. *U. S.* A saccharine secretion deposited in the honey-comb by Apis mellifica. *Br.*

Miel, *Fr.;* Honig, *Germ.;* Miele, *Ital.;* Miel, *Span.*

Naturalists have not yet determined whether honey is a secretion of the bee, *Apis mellifica*, or whether it exists already formed in plants. It is certain that the nectaries of flowers contain a saccharine matter, which is extracted by the insect; and the fact is well known that the flavour and character of honey are very much affected by the nature of the plants which predominate in the vicinity of the hive; so much so that, when these plants are poisonous, the fluid sometimes partakes of their noxious qualities. Several cases of poisoning from eating honey from a particular source, are recorded in the *New Jersey Med. Reporter*

for November, 1852 (p. 46). Still, it probably undergoes change in the organs of the bee; as the saccharine matter of the nectaries, so far as it has been possible to examine it, wants some of the characteristic properties of honey.*

The finest honey is that which is allowed to drain from the comb. If obtained from hives that have never swarmed, it is called *virgin honey*. An inferior kind is procured by submitting the comb to pressure; and, if heat be employed previous to expression, the product is still more impure.

Honey is collected in different parts of the United States; but much also of that used in the shops is imported from the West Indies.

In the recent state honey is fluid; but, on being kept, it is apt to form a crystalline deposit, and to be ultimately converted into a soft granular mass. In the shops it is found of every consistence, from that of a viscid liquid like thin syrup or oil, to that of lard or soft suet. Its colour is sometimes white, but usually yellowish, and occasionally of a brown or reddish tinge. It has a peculiar agreeable odour, varying somewhat with the flowers from which it was collected, and a very sweet, feebly aromatic taste, which is followed by a slight prickling, or sense of acrimony in the fauces. Its sp. gr. is about 1·333. (*Duncan.*) Cold water dissolves it readily, alcohol with less facility. It contains crystallizable sugar analogous to that of grapes, and, according to Soubeiran, two other kinds of sugar, one of which is changed by acids, and has the property of turning to the right the plane of polarization; and the other, not acted on by acids, and possessed of a strong left-handed rotating power. The first of these two sugars is not always present; as there is reason to believe that it is in time wholly changed by acid into granular sugar. It is especially abundant in the honey taken from the comb. The second variety is very similar to the uncrystallizable sugar produced by the reaction of acids on cane sugar, being identical with it in composition, and like it incapable of crystallizing, and very sensitive to the

* *Propolis. Bee-bread.* The subjects considered in the present note would probably have been more properly treated under the head of Cera; but the observations recently made in the journals in relation to them did not come under the notice of the author until too late for insertion there. The object of this note is to call attention to two communications contained in the journals of the past and present years.

Propolis. In the *Med. and Surg. Reporter* for Nov. 2, 1867 (p. 382), extracted from the *Chicago Med. Journ.*, is a short paper by Dr. H. O. Hitchcock, of Kalamazoo, Michigan, giving an account of his experience with propolis as a remedy. This is a resinous substance, deposited by bees at the base of the hive, and in other parts which required protection from the outer air, of a nature entirely different from wax or honey, and supposed to be intended for the protection of the comb from injurious external agencies. Dr. Hitchcock considers it as one of the best remedies in simple mucous diarrhœa, even when severe, and attended with pain and vomiting. In many cases only a single dose is required. It appears to possess anodyne and soporific properties. He has found it also efficacious in dysentery in the early stage; but it has proved useless in the disease when fully established. In chronic diarrhœa, even of the kind contracted in camp, and remarkable for its obstinacy, it has seemed to act like a charm. It is of a dark reddish or yellowish brown colour, of a shining fracture, an aromatic taste and smell, quite insoluble in water, nearly so in ether, but readily dissolved by alcohol and solution of potassa. Dr. Hitchcock has used both a tincture and an alkaline solution; the former made with two drachms of propolis and four fluidounces of alcohol, and given to adults in doses of from thirty minims to a fluidrachm; the latter with two drachms of the resin to a fluidrachm of liquor potassæ and four fluidounces of a menstruum consisting of equal parts of water and simple syrup, and given in the dose of half a fluidrachm after each stool.

Bee-bread. This was brought to notice in the *Chicago Med. Examiner* (Sept. 1865) by Dr. Jas. S. Whitmire, who was led accidentally to the discovery of its possession of extraordinary diuretic powers. Trying the remedy upon himself, in the dose of a drachm three times a day, he found a great increase of the secretion produced; and, continuing to take it in the same quantities for a week, he passed during that time from four to six pints of urine daily. The effect was greatest during exercise in the open air; within-doors, the quantity per day was lessened by a pint or a pint and a half. He extended the experiment to his children, with the same result. No disagreeable effects followed its use, unless a slight flatulency and looseness of the bowels. It is entirely palatable and inoffensive t. the stomach. (See *Am. Journ. of Pharm.*, Jan. 1866, p. 56.) Bee-bread is the name given to a material found in some of the cells of the comb, consisting mainly of the pollen of plants; and supposed to be intended specially for the food of the young bees, and necessary for their development. (*Note to the thirteenth edition.*)

action of alkalies. But it is distinguished by the impossibility of converting it into granular sûgar, and by having nearly twice the rotating power of common uncrystallizable sugar. (*Journ. de Pharm.*, 3e sér., xvi. 252.) Honey contains, besides these saccharine principles, an aromatic principle, an acid, wax, and, according to Guibourt, a little mannite. The crystalline sugar may be obtained by treating granular honey with a small quantity of alcohol, which, when expressed, takes along with it the other ingredients, leaving the crystals nearly untouched. The same end may be attained by melting the honey, saturating its acid with carbonate of lime, filtering the liquid, then setting it aside to crystallize, and washing the crystals with alcohol. Inferior honey usually contains a large proportion of uncrystallizable sugar and vegetable acid. Diluted with water, honey undergoes the vinous fermentation.

In warm weather, honey, if not very pure, sometimes ferments, acquiring a pungent taste and deeper colour. Starch is said to be occasionally added to the inferior kinds to give them a white appearance. The adulteration may be detected by dilution with water, which dissolves the honey and leaves the starch at the bottom of the vessel. The nature of the deposit may be tested by the tincture of iodine. Water is said to be sometimes added to honey to increase its bulk. Its presence may be suspected from the greater thinness of the liquid, and its want of disposition to crystallize.

Medical Properties and Uses. Honey possesses the same medical properties with sugar, but is more disposed to run off by the bowels, and to occasion griping pain. Though largely consumed as an article of food, it is seldom employed medicinally, except as the vehicle of more active substances. Its taste and demulcent qualities render it a useful addition to gargles; and it is sometimes employed as an application to foul ulcers, and in the form of enema.

Off. Prep. Mel Depuratum, *Br.;* Mel Despumatum, *U. S.* W.

MELISSA. *U. S. Secondary.*

Balm.

The herb of Melissa officinalis. *U. S.*

Mélisse, *Fr.;* Garten-Melisse, *Germ.;* Melissa, *Ital.;* Torongil, *Span.*

Melissa. *Sex. Syst.* Didynamia Gymnospermia. — *Nat. Ord.* Lamiaceæ or Labiatæ.

Gen. Ch. Calyx dry, nearly flat above; with the upper lip sub-fastigiate. *Corolla*, upper lip somewhat arched, bifid; lower lip with the middle lobe cordate. *Willd.*

Melissa officinalis. Willd. *Sp. Plant.* iii. 146; Woodv. *Med. Bot.* p. 334, t. 119. Balm has a perennial root, which sends up annually several erect quadrangular stems, usually branched towards the base, and a foot or two in height. The leaves are opposite, ovate or cordate, deeply serrate, pubescent; the lower on long footstalks, the uppermost nearly sessile. The flowers are white or yellowish, upon short peduncles, and in axillary whorls, surrounding only half the stem. The calyx is tubular, pentangular, and bilabiate, with the upper lip tridentate and flattened, the lower cut into two pointed teeth. The corolla is also tubular and bilabiate, the upper lip less convex and notched, the lower three-cleft. The plant is a native of the south of Europe. It has been introduced into this country, where it is cultivated in gardens, and grows wild along the fences of our roads and lanes. For use the herb should be cut before the appearance of the flowers, which begin to expand in July.

In the fresh state, it has a fragrant odour very similar to that of lemons; but is nearly inodorous when dried. The taste is somewhat austere, and slightly aromatic. The herb contains a minute proportion of a yellowish or reddish-yellow essential oil, which has its peculiar flavour in a very high degree. It contains also tannin, bitter extractive, and gum.

Medical Properties and Uses. Balm scarcely produces any remedial effects

upon the system. The quantity of oil which it contains is not more than sufficient to communicate an agreeable flavour to the infusion, which forms an excellent drink in febrile complaints, and when taken warm tends to promote the operation of diaphoretic medicines. W.

MENTHA PIPERITA. *U.S.*

Peppermint.

The herb of Mentha piperita. *U.S.*

Menthe poivrée, *Fr.;* Pfeffermünze, *Germ.;* Menta piperita, *Ital.;* Pimenta piperita, *Span.*

MENTHA. *Sex. Syst.* Didynamia Gymnospermia. — *Nat. Ord.* Lamiaceæ or Labiatæ.

Gen. Ch. Corolla nearly equal, four-cleft; the broader segment emarginate *Stamens* upright, distant. *Willd.*

Several species of Mentha possess medicinal properties. Besides the two here described, M. piperita, namely, and M. viridis, the *Mentha Pulegium*, under the name of *pulegium* or *pennyroyal*, long held a place in the British Pharmacopœias. It has, however, been discarded, and in the present Br. Pharmacopœia is not recognised. As in the other species, the herb in flower was employed, both fresh and dried. The plant is specifically characterized by its roundish prostrate stems, its ovate, obtuse, somewhat crenate leaves, and its verticillate flowers. It is a native of Europe, and neither cultivated nor employed in this country; our native pennyroyal belonging to a different genus. (See *Hedeoma Pulegioides.*) Pulegium possesses similar properties, and has been employed for the same purposes, and in the same manner with the other mints. It was used in the forms of water, spirit, and volatile oil.

Mentha piperita. Willd. *Sp. Plant.* iii. 79; Woodv. *Med. Bot.* p. 336, t. 120; Carson, *Illust. of Med. Bot.* ii. 16, pl. 63. Peppermint is a perennial herbaceous plant, with a creeping root, and quadrangular, channeled, purplish, somewhat hairy stems, branched towards the top, and about two feet in height. The leaves are opposite, petiolate, ovate, serrate, pointed, smoother on the upper than the under surface, and of a dark-green colour, which is paler beneath. The flowers are small, purple, and in terminal obtuse spikes, interrupted below. The calyx is tubular, furrowed, and five-toothed; the corolla is also tubular, with its border divided into four segments, of which the uppermost is broadest, and notched at its apex. The anthers are concealed within the tube of the corolla; the style projects beyond it, and terminates in a bifid stigma. The four-cleft germ is converted into four seeds, which are lodged in the calyx.

This species of mint is a native of Great Britain, whence it has been conveyed to the continent of Europe and to this country. In some parts of the United States, especially in New England, Michigan,* the western part of New York, Ohio, and New Jersey, it is largely cultivated for the sake of its volatile oil. We occasionally find it growing wild along the fences of our villages. The cultivators of this herb have observed that, in order to maintain its flavour in perfection, it is necessary to transplant the roots every three years. It should be cut for medical use in dry weather, about the period of the expansion of the flowers. These appear in August.

The herb, both in the recent and dried state, has a peculiar, penetrating,

* For an account of the cultivation of the plant in Michigan, from one county of which, that of St. Joseph, it is stated that, "for the last ten years, the largest proportion of the oil of peppermint, produced in the world, has been sent," see a paper by Mr. Frederick Stearns, of Detroit, in the *Am. Journ. of Pharm.*, Jan. 1859, p. 33.

For some interesting remarks in relation to the cultivation of peppermint in England, the reader is referred to the *Am. Journ. of Pharm.* (xxiii. 239).

This plant has recently become an object of special culture in France, and a pamphlet by M. Roze is devoted to the history of this industry, both in its agricultural and pharmaceutical relations. The reader is referred to the *Journ. de Pharm. et de Chim.* (Août, 1868, p. 125) for an abstract of the more interesting facts recorded in the work. (***Note to the thirteenth edition.***)

grateful odour. The taste is aromatic, warm, pungent, glowing, camphorous, bitterish, and attended with a sensation of coolness when air is admitted into the mouth. These properties depend on a volatile oil, which abounds in the herb, and may be separated by distillation with water. (See *Oleum Menthæ Piperitæ*.) The leaves are said to contain a little tannic acid. The virtues of the herb are imparted to water, and more readily to alcohol.

Medical Properties and Uses. Peppermint is a grateful aromatic stimulant, much used for all the purposes to which medicines of this class are applied. To allay nausea, relieve spasmodic pains of the stomach and bowels, expel flatus, and cover the taste or qualify the nauseating or griping effects of other medicines are among the most common of these purposes. The fresh herb, bruised and applied to the epigastrium, often allays sick stomach, and is useful in the cholera of children. The medicine may be given in infusion; but the volatile oil, either alone, or in some state of preparation, is generally preferred.

MENTHA VIRIDIS. *U. S.*

Spearmint.

The herb of Mentha viridis. *U. S.*

Menthe à épi, *Fr.;* Grune Münze, *Germ.;* Menta Romana, *Ital.;* Yerba buena puntiaguda, *Span.*

MENTHA. See MENTHA PIPERITA.

Mentha viridis. Willd. *Sp. Plant.* iii. 76; Woodv. *Med. Bot.* p. 338, t. 121. Spearmint, sometimes called simply *mint*, differs from *M. piperita* chiefly in having sessile or nearly sessile, lanceolate, naked leaves; elongated, interrupted, panicled spikes; setaceous bractes; and stamens longer than the tube of the corolla. Like the preceding species, it is a native of Europe. In this country it is cultivated in gardens for domestic use, and in some places more largely for the sake of its oil. It also grows wild in low grounds, in long-settled parts of the country. Its flowering season is August. According to Thomson, it should be cut in very dry weather, and, if intended for medical use, just as the flowers appear; if for obtaining the oil, after they have expanded.

The odour of spearmint is strong and aromatic, the taste warm and slightly bitter, less pungent than that of peppermint, but considered by some as more agreeable. These properties are retained for some time by the dried plant. They depend on a volatile oil, which is obtained by distillation, and is imparted to alcohol and water by maceration. (See *Oleum Menthæ Viridis.*)

Medical Properties. The virtues and applications of this plant are the same as those of peppermint.

MEZEREUM. *U. S.*

Mezereon.

The bark of Daphne Mezereum, and of Daphne Gnidium. *U. S.*

Off. Syn. MEZEREI CORTEX. *Mezereon Bark.* The dried bark of Daphne Mezereum, *Mezereon;* or of Daphne Laureola, *Spurge Laurel. Br.*

Bois gentil, *Fr.;* Kellerhals, *Germ.;* Mezereo, *Ital.;* Mecereon, *Span.*

DAPHNE. *Sex. Syst.* Octandria Monogynia. — *Nat. Ord.* Thymelaceæ.

Gen. Ch. Calyx none. *Corolla* four-cleft, withering, enclosing the stamens. *Drupe* one-seeded. *Willd.*

All the species of Daphne are possessed of active properties; but three only are officinal—*D. Mezereum, D. Laureola,* and *D. Gnidium*—the first two of which are recognised in the British Pharmacopœia, the last in the French Codex, and the first and last in the Pharmacopœia of the United States.

1. *Daphne Mezereum.* Willd. *Sp. Plant.* ii. 415; Woodv. *Med. Bot.* p. 717,

t. 245; Carson, *Illust. of Med. Bot.* ii. 26, pl. 72. This is a very hardy shrub, three or four feet high, with a branching stem, and a smooth dark-gray bark, very easily separable from the wood. The leaves spring from the ends of the branches, are deciduous, sessile, obovate-lanceolate, entire, smooth, of a pale-green colour, somewhat glaucous beneath, and about two inches long. They are preceded by the flowers, which appear very early in spring, and sometimes bloom even amidst the snow. These are of a pale-rose colour, highly fragrant, and disposed in clusters, each consisting of two or three flowers, forming together a kind of spike at the upper part of the stem and branches. At the base of each cluster are deciduous floral leaves. The fruit is oval, shining, fleshy, of a bright-red colour, and contains a single round seed. Another variety produces white flowers and yellow fruit.

This species of Daphne is a native of Great Britain and the neighbouring continent, in the northern parts of which it is particularly abundant. It is cultivated in Europe both for medicinal purposes and as an ornamental plant, and is occasionally found in our own gardens. It flowers in February, March, or April, according to the greater or less mildness of the climate.

2. *Daphne Gnidium.* Willd. *Sp. Plant.* ii. 420. In this species, called *garou* or *sain-bois* by the French, the leaves are linear-lanceolate, acute, entire, smooth, and irregularly but closely set upon the branches. The flowers are white, downy, odoriferous, and disposed in terminal panicled racemes. The fruit is globular, dry, at first green, but ultimately black. *D. Gnidium* grows in dry uncultivated places in the south of Europe, and flowers in June. In France its bark is used indiscriminately with that of the former species.

Besides the species above described, *Daphne Laureola*, or *spurge laurel*, is said to furnish a portion of the mezereon of commerce, and is recognised by the Br. Pharmacopœia; but its product is inferior in acrimony, and consequently in medicinal activity.

The bark of the root was formerly directed; but the mezereon with which our markets are supplied is evidently the bark of the stem; and the Pharmacopœias at present very properly direct the bark, without designating the part from which it must be taken. British writers state that the bark of the root is the most active. The berries and leaves of the plant are also active; and the former have sometimes proved fatal to children who have eaten them. Pallas states that they are used as a purgative by the Russian peasants, and that thirty berries are required to act. French authors observe that fifteen are sufficient to kill a Frenchman. A tincture of them is used in Germany as a local application in neuralgia. (*Ann de Thérap.*, 1854, p. 42.) Mezereon is brought to us chiefly from Germany.

Properties. Mezereon, as it comes to us, is usually in strips, from two to four feet long and an inch or less in breadth, sometimes flat, sometimes partially rolled, and always folded in bundles, or wrapped in the shape of balls. It is covered externally with a grayish or reddish-brown wrinkled epidermis, very thin, and easily separable from the bark. Beneath the epidermis is a soft, greenish tissue. The inner bark is tough, pliable, fibrous, striated, and of a whitish colour. When fresh it has a nauseous smell, but in the dry state is nearly inodorous. Its taste is at first sweetish, but afterwards highly acrid and even corrosive. It yields its virtues to water by decoction.

Vauquelin discovered a peculiar principle in the bark of *Daphne Alpina*. This has subsequently been found in other species, and has received the name of *daphnin*. Gmelin and Bär found it in the bark of *D. Mezereum*, associated with wax, an acrid resin, a yellow colouring matter, reddish-brown extractive, an uncrystallizable and fermentable sugar, a gummy matter containing azote, ligneous fibre, malic acid, and several malates. By J. B. Eng it has been discovered, together with a volatile oil, in the flowers of Daphne Mezereum. (*Wittstein's Viert. Schr.*, viii. 23.) *Daphnin* is in prismatic crystals grouped together, colourless, transparent, brilliant, slightly soluble in cold water, very soluble in boiling water and alcohol, without odour, and of a bitter, somewhat austere taste. By Zwenger it is said to be insoluble in ether. The same chemist states

that it has an acid reaction, and acts like the glucosides, being resolvable by sulphuric or muriatic acid into sugar, and a peculiar crystallizable principle called *daphnetin*. He gives for daphnin the formula $C_{62}H_{34}O_{38}+8HO$. (*Annal. der Chem. und Pharm.*, cxv. 1.) It is obtained by treating the alcoholic extract of the bark with water, decanting the solution, precipitating with subacetate of lead, filtering, decomposing the excess of the subacetate by sulphuretted hydrogen, again filtering, evaporating to dryness, submitting the residue to the action of anhydrous alcohol, and evaporating the alcoholic solution to the point of crystallization. Though daphnin is probably not inert, it is not the principle upon which the virtues of mezereon chiefly depend. Vauquelin thinks that in the recent plant they reside in an essential oil, which by time and exposure is changed into a resin, without losing its activity. The acrid resin, observed by Gmelin and Bar, is probably the characteristic principle to which the bark owes its vesicating properties. It is obtained separate by boiling mezereon in alcohol, allowing the liquor to cool in order that it may deposit some wax which it has taken up, then distilling off the alcohol, and treating the residue with water, which leaves the resin. This is of a dark-green, almost black colour, hard and brittle, and of an exceedingly acrid and permanent taste. In the isolated state it is slightly soluble in water; and it is much more so when combined with the other principles of the bark. It appears, however, not to be a pure proximate principle, but rather a resinoid combination of an acrid fixed oil with another substance. The acrid principle of mezereon is partially given off by decoction with water, as proved by the irritating character of the vapour when inhaled; but none of it appears to escape when the bark is boiled with alcohol. (Squire, *Pharm. Transact.*, i. 395.)

Medical Properties and Uses. The recent bark applied to the skin produces inflammation followed by vesication, and has been popularly used as an epispastic, from time immemorial, in some of the southern countries of Europe. The dried bark, though less active, is possessed of a similar property, and is occasionally employed in France by regular practitioners for the purpose of forming issues. A small square piece, moistened with vinegar, is applied to the skin, and renewed twice a day till a blister is formed, and occasionally afterwards to keep up the discharge. It is slow in its operation, generally requiring from twenty-four to forty-eight hours to vesicate. An irritant ointment is prepared from mezereon, which is used for maintaining the discharge from blistered surfaces, and may be applied advantageously to obstinate, ill-conditioned, indolent ulcers. In the U. S. Pharmacopœia of 1850, it was directed to be made by digesting the bark with melted lard, and straining; but was discarded at the last revision of that work. This, we think, was unfortunate; for, though the method of preparing it was defective, another might have been adopted, which would have yielded a good preparation, and an irritating ointment of the kind is needed. It may be made by mixing two drachms of an alcoholic extract of mezereon with nine ounces of lard and one of wax, melted together. The alcoholic extract has also been employed to communicate irritant properties to issue peas.

Internally administered, mezereon is a stimulant capable of being directed to the skin or kidneys, and in large doses apt to excite purging, nausea, and vomiting. In overdoses it produces the fatal effects of the acrid poisons; and a case of apparently severe narcotic effects has been recorded. (*Am. Journ. of Med. Sci.*, xxi. 518.) It had at one time much reputation as a remedy in the secondary stages of syphilis, and still enters as an ingredient into the officinal compound decoction of sarsaparilla. It has also been thought to act favourably as an alterative in scrofulous affections, chronic rheumatism, and obstinate diseases of the skin. For this purpose it is usually administered in decoction. (See *Decoctum Mezerei.*) Dr. Withering cured a case of difficult swallowing from palsy, by directing the patient to chew frequently small pieces of the root. The dose of the bark in substance is ten grains; but it is seldom used in this way.

Horsemint.

The herb of Monarda punctata. *U. S.*

MONARDA. *Sex. Syst.* Diandria Monogynia. — *Nat. Ord.* Lamiaceæ or Labiatæ.

Gen. Ch. Calyx five-toothed, cylindric, striate. *Corolla* ringent, with a long cylindric tube; *upper lip* linear, nearly straight and entire, involving the filaments; *lower lip* reflected, broader, three-lobed, the middle lobe longer. *Nuttall.*

Monarda punctata. Willd. *Sp. Plant.* i. 126; *Am. Med. Recorder*, vol. ii. p. 496. This is an indigenous perennial or biennial plant, with herbaceous, obtusely angled, downy, whitish, branching stems, rising one or two feet in height, and furnished with oblong-lanceolate, remotely serrate, smooth, punctate leaves. The flowers are yellow, spotted with red or brown, and disposed in numerous whorls, provided with lanceolate, coloured bractes, longer than the whorl.

The horsemint grows in light gravelly or sandy soils from New Jersey to Louisiana, and flowers from June to September. The whole herb is employed. It has an aromatic smell, and a warm, pungent, bitterish taste, and abounds in a volatile oil, which may be separated by distillation with water.

Medical Properties and Uses. Horsemint is stimulant and carminative; but is seldom used in regular practice. In the state of infusion it is occasionally employed in families as a remedy for flatulent colic and sick stomach, and for other purposes to which the aromatic herbs are applied. It was introduced into the primary catalogue of the U. S. Pharmacopœia, on account of the volatile oil which it affords. (See *Oleum Monardæ.*)

MORI SUCCUS. *Br.*

Mulberry Juice.

The juice of the ripe fruit of Morus nigra. *Br.*

Mures, *Fr.;* Schwarze Maulbeeren, *Germ.;* Morone, *Ital.;* Moras, *Span.*

MORUS. *Sex. Syst.* Monœcia Tetrandria. — *Nat. Ord.* Urticaceæ.

Gen. Ch. MALE. *Calyx* four-parted. *Corolla* none. FEMALE. *Calyx* four-leaved. *Corolla* none. *Styles* two. *Calyx* berried. *Seed* one. *Willd.*

Morus nigra. Willd. *Sp. Plant.* iv. 36; Woodv. *Med. Bot.* p. 712, t. 243. This species of Mulberry is distinguished by its cordate-ovate or lobed, unequally toothed, and scabrous leaves It is a tree of middle size, supposed to have been brought originally from Persia into Italy, and thence spread over Europe and America. Its leaves afford food for the silk-worm; and the bark of the root, which is bitter and slightly acrid, has been employed as a vermifuge, especially in cases of the tape-worm, in the dose of two drachms infused in eight ounces of boiling water. The juice of the fruit is the officinal portion.

The fruit is oblong-oval, of a dark reddish-purple almost black colour, and consists of numerous minute berries, united together and attached to a common receptacle, each containing a single seed, the succulent envelope of which is formed by the calyx. It is inodorous, has a sweet, mucilaginous, acidulous taste, and abounds in a deep-red juice. The sourish taste is owing, according to Hermbstadt, to the presence of tartaric acid.

Medical Properties and Uses. Mulberries are refreshing and laxative, and

serve to prepare a grateful drink well adapted to febrile cases. A syrup is made from their juice, and used as an agreeable addition to gargles in inflammation of the throat. They are, however, more used as food than medicine. Our native mulberry, the fruit of *Morus rubra*, is quite equal to that of the imported species. *Morus alba*, originally from China, and now extensively cultivated as a source of food for the silk-worm, bears a white fruit, which is sweeter and less grateful than the others.

MOSCHUS. *U. S., Br.*

Musk.

A peculiar concrete substance obtained from Moschus moschiferus. *U. S.* The inspissated and dried secretion from the preputial follicles. *Br.*

Musc, *Fr.;* Bisam, *Germ.;* Muschio, *Ital.;* Almizcle, *Span.*

Moschus. *Class* Mammalia. *Order* Pecora.

Gen. Ch. Horns none. *Fore teeth* eight in the lower jaw. *Tusks* one on each side, in the upper jaw, projecting out of the mouth.

Moschus moschiferus. Gmelin, *Syst. Nat.* i. 172; Reese's *Cyclopædia.* This animal bears a close resemblance to the deer in shape and size. It is usually about three feet in length and two feet high, with haunches considerably more elevated than the shoulders. From its upper jaw two tusks project downwards out of the mouth, each about two inches long, curved backwards, and serving to extract the roots which are used as food by the animal. The ears are long and narrow, and the tail very short. The fleece, consisting of strong, elastic, undulated hairs, varies in colour with the season, the age of the animal, and perhaps the place which it inhabits. The general colour is a deep iron-gray. The individual hairs are whitish near the root, and fawn-coloured or blackish towards the tip. The musk is contained in an oval, hairy, projecting sac, found only in the male, situated between the umbilicus and the prepuce, from two to three inches long, and from one to two broad, opening by a small hairy orifice at its anterior part, and marked posteriorly by a groove or furrow which corresponds with the opening of the prepuce. It is lined internally by a smooth membrane, thrown into a number of irregular folds, forming incomplete partitions. In the vigorous adult animal, the sac sometimes contains six drachms of musk; but in the old, seldom more than two drachms, and none in the young.* The musk is secreted by the lining membrane, and in the living animal forms a consistent mass, which, on the outside, is compact, and marked with the folds of the membrane, but is less firm towards the centre, where there is sometimes a vacant space. As first secreted it is probably liquid, and a portion is occasionally forced out by the animal, to which it communicates its odour.

The musk deer inhabits the vast mountainous regions of central Asia, extending from India to Siberia, and from the country of the Turcomans to China. It is an active and timid animal, springing from rock to rock with surprising agility, and frequenting the snowy recesses and most inaccessible crags of the mountains. Concealing itself during the day, it chooses the night for roaming in search of food; and, though said to be abundant in its native regions, is taken with difficulty. It is hunted for its hide, as well as for the musk. The natives often take it by snaring. As soon as the animal is killed, the sac is cut off, and dried with its contents; and in this state is sent into the market.

Musk varies in quality with the country inhabited by the animal. That procured from the mountains on the southern borders of Siberia, and brought into the market through Russia, is comparatively feeble. The best is imported from

* According to Col. Frederick Markham, as much as two ounces are sometimes found, and the average for a full-grown animal is an ounce; but, as many of the deer are killed young, the pods in the market probably do not contain more than half an ounce upon an average. He states that the musk of the young animal, though not so strong as that of the old, has a much pleasanter smell. (*Pharm. Journ. and Trans.*, xv. 472; from "*Shooting in the Himalayas*," &c.)—*Note to the eleventh edition.*

China, and is said to be the product of Tonquin. A variety intermediate between these is procured in the Himalaya Mountains and Thibet, and sent to Calcutta. This is sometimes enclosed in the membranous lining of the sac, without the hairy envelope, and in this condition is said to be quite equal if not superior to that surrounded by the skin, as, in the former condition, it dries readily in the sun, while, in the latter, the aid of artificial heat is deemed necessary, by which the musk may sometimes be injured. (F. Peake, *Pharm. Journ.*, Feb. 1861, p. 399.) We derive our chief supply from Canton, though portions are occasionally brought hither from Europe.

Two varieties are known in commerce, the Chinese and Russian. Both come in sacs, convex and hairy on one side, flat and destitute of hair on the other. The hairs are brownish-yellow, grayish, or whitish, stiff and short, and arranged concentrically around the orifice of the sac. The Chinese, which is the most highly valued, is in bags of a rounder shape, covered with brownish-yellow or reddish-brown hairs, and containing at most a drachm and a half of large-grained, dark, strong-scented musk, of an ammoniacal odour. The Russian is in longer and larger bags, small-grained, of a light yellowish-brown colour, and of a weaker and more fetid odour, with less smell of ammonia.

Properties. Musk is in grains or lumps concreted together, soft and unctuous to the touch, and of a reddish-brown or ferruginous colour resembling that of dried blood. Some hairs of the pod are generally mixed with it. The odour is strong, penetrating, and so diffusive, that one part of musk communicates its smell to more than 3000 parts of inodorous powder. (*Fée.*) In some delicate individuals it produces headache and other disagreeable symptoms, and has even caused convulsions. The taste is bitter, disagreeable, and somewhat acrid. The colour of the powder is reddish-brown. Musk is inflammable, burning with a white flame, and leaving a light spongy charcoal. Reduced to ashes, it leaves about 5 per cent., containing potassa, lime, magnesia, iron, carbonic, phosphoric, and sulphuric acids, chlorine, and traces of ferrocyanate of potassa and sulphuret of ammonium. (*Prof. W. Bernatzik.*) It yields, upon analysis, a great number of proximate principles. Guibourt and Blondeau obtained water, ammonia, stearin, olein, cholesterin, an oily acid combined with ammonia, volatile oil, muriate of ammonia, chlorides of potassium and calcium, an uncertain acid combined with ammonia, potassa, and lime, gelatin, albumen, fibrin, a highly carbonaceous matter soluble in water, a soluble calcareous salt with a combustible acid, carbonate and phosphate of lime, hair, and sand. (*Annal. de Chim. et de Phys.*, ix. 327.) Besides these constituents, Geiger and Reinman found a peculiar bitter resin, osmazome, and a peculiar substance in part combined with ammonia. According to Guibourt and Blondeau, it contains 47 per cent. of volatile matter, thought by some to be chiefly ammonia, by others to be a compound of ammonia and volatile oil. Theimann obtained only from 10 to 15 per cent. But the quantity of volatile as well as of soluble matter varies exceedingly in different specimens. Thus, Theimann found from 80 to 90 per cent. of matter soluble in water, Buchner only 54·5 per cent., and other chemists intermediate proportions. The proportion soluble in alcohol, as ascertained by different experimenters, varies from 25 to 62 per cent. Ether is a good solvent. The watery infusion has a yellowish-brown colour, a bitterish taste, a strong smell of musk, and an acid reaction. The alcoholic tincture is transparent, and of a reddish-brown colour, with the peculiar odour of the medicine. The action of potassa upon musk is accompanied with the extrication of ammonia, and an increase of its peculiar odour. By the influence of heat and moisture long continued, ammonia is developed, which acts upon the fatty matter, producing a substance resembling adipocire, but, according to Guibourt, without diminishing the activity of the medicine. The correctness, however, of this opinion is perhaps questionable; and it is advisable to preserve the musk as much as possible unaltered. When kept in glass bottles, in a situation neither moist nor very dry, it remains for a great length of time without material change. The odour of musk is very much diminished by mixing it with emulsion or syrup of bitter almonds, or cherry-laurel water. From

the experiments of Wimmer, it appears that musk loses its odour when rubbed with kermes mineral, or golden sulphur of antimony, and reacquires it on the addition of a little solution of ammonia. (*Pharm. Cent. Blatt*, A. D. 1843, p. 406.) Camphor rubbed up with musk is also said to destroy its odour.

Adulterations. The price of this medicine is so high, and its sources so limited, as to offer strong temptations to adulteration; and little genuine unmixed musk is to be found in the market. The sophistication commences in China, and is completed in Europe and this country. A common practice in the East is to open the sac, and to supply the place of the musk with an adulterated mixture. Sometimes the scrotum of the animal is filled with this mixture, and not unfrequently the sacs are made out of the skin. Dried blood, from its resemblance to musk, is among the most common adulterations; but, besides this, sand, lead, iron-filings, hair, animal membrane, tobacco, the dung of birds, wax, benzoin, storax, asphaltum, artificial musk, and other substances are introduced. These are mixed with a portion of musk, the powerful odour of which is diffused through the mass, and renders the discovery of the fraud sometimes difficult. It is said that the Chinese sometimes mix the musk of Tonquin with that of Siberia. The bags containing the drug should have the characters before described as belonging to the natural sac, and should present no evidence of having been opened. The slit is sometimes carefully sewed up, sometimes glued together. The former condition may be discovered by close inspection, the latter by immersion in hot water. When the bag is made from any other portion of the skin, the difference may be detected, according to Mr. Neligan, by a microscope which magnifies 300 diameters. The genuine hairs exhibit innumerable cells, which are wanting in the spurious. (*Chem. Gaz.*, Feb. 1846, p. 79.) Musk which burns with difficulty, has a feeble odour and a colour either pale or entirely black, feels gritty to the finger, is very moist so as to lose much weight in drying, or contains obvious impurities, should be rejected. Russian musk is said never to be adulterated before leaving Russia.*

Medical Properties and Uses. Musk is stimulant and antispasmodic, increasing the vigour of the circulation, and exalting the nervous energy, without producing, either as an immediate or secondary effect, any considerable derangement of the purely cerebral functions. Its medical uses are such as may be inferred from its general operation. In almost all spasmodic diseases, so far as mere relaxation of spasm is desirable, it is more or less efficacious; but peculiar advantage may be expected from it when a prostrate state of the system, attended with great nervous agitation, or irregular muscular action, calls for the united influence of a highly diffusible stimulant and powerful antispasmodic. Such are low cases of typhous disease, accompanied with subsultus tendinum, tremors, and singultus. Such also are many instances of gout in the stomach, and other spasmodic affections of that organ. In very obstinate hiccough we have found it more effectual than any other remedy; and have seen great advantage from its use in those alarming convulsions of infants originating in spasm of the intestines. In the laryngismus stridulus or crowing disease of infants, M. Bouchut relies mainly on musk, having found it more efficacious than any of the narcotics. (*N. Y. Med. Journ.*, Sept. 1868, p. 545.) It is said to have done much good, combined with opium, and administered in very large doses, in tetanus. Epilepsy, hysteria, asthma, pertussis, palpitations, cholera, and colic are also among the spasmodic affections in which circumstances may render its employment desirable. The chief obstacles to its general use are its high price, and the uncertainty in regard to its purity. Musk was unknown to the ancients. Aëtius was the first writer who noticed it as a medicine. It was in-

* For an account of the effects of numerous reagents on musk, and other modes of identification as well as of detecting adulterations, see a paper by Prof. W. Bernatzik, translated in the *Am. Journ. of Pharm.* for Sept. 1861, p. 427. There is a discrepancy between Prof. Bernatzik's statement of the solubilities of musk and that of the text. According to the latter, ether is a good solvent; according to the former, ether and chloroform possess scarcely any solvent power. (*Note to the twelfth edition.*)

troduced into Europe through the Arabians, from whose language its name was derived.

It may be given in the form of pill or emulsion. In preparing mixtures of musk, it is recommended by M. Lailler, of France, to rub the musk up first with a very little boiling water, afterwards with a larger quantity, and to add the liquid thus prepared to whatever mixture may be prescribed. According to this writer, the insolubility of musk in cold water, and its much greater solubility in that liquid when boiling hot, render this mode of preparation much preferable to rubbing up with cold water. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 291.) The medium dose is ten grains, to be repeated every two or three hours. To children it may be administered with great advantage in the form of enema.* W.

Calyx campanulate, bilabiate; the lower lip trifid, with acute segments, the middle one longest; the upper lip broader, entire, obtuse. *Corolla* with the vexillum ascending, shorter than the wings and keel; the wings oblong, equal to the keel in length; the keel oblong, straight, acute. *Stamens* diadelphous, with five anthers oblong-linear, and five ovate, hirsute. *Legume* oblong, torose, bivalvular, with cellular partitions. *Seeds* roundish, surrounded circularly by a linear hilum. (*De Candolle.*)

Mucuna pruriens. De Cand. *Prodrom.* ii. 405; Lindley, *Flor. Med.* p. 254.—*Dolichos pruriens.* Willd. *Sp. Plant.* iii. 1041; Woodv. *Med. Bot.* p. 422.—*Stizolobium pruriens.* Persoon. This is a perennial climbing plant, with an herbaceous branching stem, which twines round the trees in its vicinity, and rises to a considerable height. The leaves are pinnately trifoliate, and stand on long footstalks, placed alternately on the stem at the distance of a foot from each other. The leaflets are acuminate, smooth on their upper surface, and hairy beneath. The lateral leaflets are oblique at the base, the middle one somewhat rhomboidal. The flowers, which resemble those of the pea in form, are large, of a red or purplish colour, usually placed in threes on short peduncles, and hang from the axils of the leaves in pendant spikes about a foot in length. The fruit is a coriaceous pod, shaped like the Italic letter *f*, about four inches long, and covered with brown bristly hairs, which easily separate, and when handled stick in the fingers, producing an intense itching sensation. The plant is a native of the West Indies, and other parts of tropical America. It has been supposed to grow also in the East Indies; but the plant of that region is now considered a distinct species, and entitled *Mucuna prurita.* The part usually imported is the pod, of which the hairs are officinal.

Medical Properties and Uses. The spicula are said to possess powerful vermifuge properties, and are thought to act mechanically, by penetrating the worms. That they do act in this manner is evinced as well by the result of direct

* *Vegetable Musk.* It has been proposed to substitute for musk the volatile oil of certain plants, having the characteristic odour of that product. The *Malva moschata* and *Mimulus moschatus* have been used for this purpose. Dr. Hanon, of Belgium, has experimented with the distilled oil of these plants, and found it, in the dose of two or three drops, to be an energetic excitant of the primæ viæ and encephalon, producing a sense of weight at the epigastrium, with excitation, vertigo, headache, dryness of the pharynx and œsophagus, general lassitude, yawning, somnolence, and sleep in five or six hours. The pulse is little affected, and no unpleasant symptoms are felt on awaking. He has found it an admirable remedy in hysterical disorders, and various nervous affections attendant on other diseases when not inflammatory, and thinks that it is in no respect inferior to musk in antispasmodic properties. (*Journ. de Pharm.*, xxv. 66.)—*Note to the eleventh edition.*

experiment upon worms out of the body, as by the fact that neither the tincture nor the decoction is in the least degree anthelmintic. The medicine was first employed as a vermifuge in the West Indies, and thence passed into British practice. There can be no reasonable doubt of its efficiency. It has been chiefly employed against the round worm; but all the different species which infest the alimentary canal have been expelled by its use. It is best administered in some tenacious vehicle. The usual mode of preparing it is to dip the pods into syrup or molasses, and scrape off the hairs with the liquid, which is in a proper state for administration when it has attained the consistency of thick honey. The dose of this preparation is a tablespoonful for an adult, a teaspoonful for a child three or four years old, to be given every morning for three days, and then followed by a brisk cathartic. M. Blatin has proposed to employ cowhage as an external irritant; seven grains being mixed with an ounce of lard, and seven or eight grains of the ointment rubbed for ten, fifteen, or twenty minutes on the skin. A stinging and burning sensation is produced, followed by white elevations, which soon disappear, leaving no unpleasant effect.

The root of M. pruriens (*M. prurita*, figured in *Curtis's Bot. Mag.*, N. S., xii., Oct. 1856, tab. 4945) is said by Ainslie to be employed in the East Indies in the treatment of cholera; and both this part and the pods have been thought to possess diuretic properties. W.

Hist.* vol. ii., part iii., p. 333. Of these botanical titles, that recognised by the U. S. Pharmacopœia of 1863 has the recommendation of priority of date; M. Moschata, that of most general usage since the times of Thunberg. The nutmeg tree is about thirty feet high, with numerous branches, and an aspect somewhat resembling that of the orange tree. The leaves stand alternately on short footstalks, are oblong-oval, pointed, entire, undulated, obliquely nerved, bright-green and somewhat glossy on their upper surface, whitish beneath, and of an aromatic taste. The flowers are male and female upon different trees. The former are disposed in axillary, peduncled, solitary clusters; the latter are single, solitary, and axillary; both are minute and of a pale yellowish colour. The fruit, which appears on the tree mingled

with the flowers, is round or oval, of the size of a small peach, smooth, at first pale-green, but yellow when ripe, and marked with a longitudinal furrow. The external covering, which is at first thick and fleshy, and abounds in an austere, astringent juice, afterwards becomes dry and coriaceous, and, separating into two valves from the apex, discloses a scarlet reticulated membrane or arillus, commonly called *mace*, closely investing a thin, brown, shining shell, which contains the kernel or *nutmeg*. Not less than eight varieties of the plant are said by Crawford to be cultivated in the East Indies.

Myristica moschata is a native of the Moluccas and other neighbouring islands, and abounds especially in that small cluster distinguished by the name of Banda, whence the chief supplies of nutmegs were long derived. But the plant is now cultivated in Sumatra, Java, Singapore, Penang, Ceylon, and other parts of the East Indies; and has been introduced into the Isles of France and Bourbon, Cayenne, and several of the West India islands.

The tree is produced from the seed. It does not flower till the eighth or ninth year; after which it bears flowers and fruit together, without intermission, and is said to continue bearing for seventy or eighty years. Little trouble is requisite in its cultivation. A branch of the female tree is grafted into all the young plants when about two years old, so as to ensure their early fruitfulness. In the Moluccas the tree yields three crops annually. The fruit is gathered by the hand, and the outside covering rejected. The mace is then carefully separated, so as to break it as little as possible, is flattened, and dried in the sun, and afterwards sprinkled with salt water, with the view of contributing to its preservation. Its fine red colour is much impaired by drying. The nuts are dried in the sun or by ovens, and exposed to smoke till the kernel rattles in the shell. They are then broken open; and the kernels, having been removed and steeped for a short time in a mixture of lime and water, probably in order to preserve them from the attack of worms, are next cleaned, and packed in casks or chests for exportation. Dr. Lumsdaine has found them to keep better, if rubbed over with dry lime, than when prepared in the moist way. (See *Am. Journ. of Sci. and Arts*, Nov. 1851.)

Nutmegs are brought to this country either directly from the East Indies, or indirectly through England and Holland. They are also occasionally imported in small quantities from the West Indies.

Properties. The nutmeg (*nux moschata*) is of a roundish or oval shape, obtuse at the extremities, marked with vermicular furrows, of a grayish colour, hard, smooth to the touch, yielding readily to the knife or the grater, but not very pulverulent. When cut or broken it presents a yellowish surface, varied with reddish-brown, branching, irregular veins, which give to it a marbled appearance. These dark veins abound in oily matter, upon which the medicinal properties depend. The odour of nutmeg is delightfully fragrant, the taste warm, aromatic, and grateful. Its virtues are extracted by alcohol and ether. M. Bonastre obtained from 500 parts, 120 of a white insoluble oily substance, 38 of a coloured soluble oil (olein), 30 of volatile oil, 4 of acid, 12 of fecula, 6 of gum, 270 of lignin; and 20 parts were lost. The *volatile oil* is obtained by distillation with water. (See *Oleum Myristicæ*.) By pressure with heat an oily matter is procured from the kernels, which becomes solid on cooling, and is commonly though erroneously called *oil of mace*.

Nutmegs have been punctured and boiled in order to extract their essential oil, and the orifice afterwards closed so carefully as not to be discoverable unless by breaking the kernel. The fraud may be detected by their levity. They are also apt to be injured by worms, which, however, attack preferably the parts least impregnated with the volatile oil. The Dutch were formerly said to heat them in a stove in order to deprive them of the power of germinating, and thus prevent the propagation of the tree. The small and round nutmegs are preferred to the large and oval. They should be rejected when very light, with a feeble taste and smell, worm-eaten, musty, or marked with black veins.

A kind of nutmeg is occasionally met with, ascribed by some to a variety of

M. moschata, by others to a different species (*Myristica fatua*), which is distinguished from that just described by its much greater length, its elliptical shape, the absence of the dark-brown veins, and its comparatively feeble odour, and disagreeable taste. It has been called *male*, *wild*, or *long nutmeg*, the other being designated as the *female* or *cultivated nutmeg*.*

The *concrete* or *expressed oil of nutmeg* (Myristicæ Adeps, *Br.* 1864), commonly called *oil of mace*, is obtained by bruising nutmegs, exposing them in a bag to steam, and then compressing them strongly between heated plates. A liquid oil flows out, which becomes solid when it cools. Nutmegs are said to yield from 10 to 12 per cent. of this oil †. The best is imported from the East Indies in stone jars. It is solid, soft, unctuous to the touch, of a yellowish or orange-yellow colour more or less mottled, with the odour and taste of nutmeg. It is composed, according to Schrader, of 52·09 per cent. of a soft oily substance, yellowish or brownish, soluble in cold alcohol and ether; 43·75 of a white, pulverulent, inodorous substance, insoluble in these liquids; and 4·16 of volatile oil. The pulverulent constituent, which received from Playfair the name of *myristicin*, has a silky lustre, melts at 88°, and yields in saponification glycerin and *myristicic acid*. It may be obtained directly from nutmeg by exhausting it by means of benzole, filtering the liquid, and allowing it to crystallize by spontaneous evaporation. To purify the product, it may be dissolved in a mixture of two parts of absolute alcohol and three of benzole with the aid of heat, then filtering the liquid while hot, and setting it aside. On cooling, it deposits the pure myristicin in crystals. (*Journ. de Pharm.*, Juin, 1859, p. 471.) Analyzed by Koller, the expressed oil was found to contain, in 100 parts, 6 of a volatile oil ($C_{20}H_{16}$) analogous with the oil of mace, 70 of myristicin, 20 of olein, 3 of resin, and 1 of salts, &c. (*Arch. der Pharm.*, clxxiii. 280.) An inferior kind of the oil is prepared in Holland, and sometimes found in the shops. It is in hard, shining, square cakes, lighter coloured than that from the East Indies, and with less smell and taste. It is supposed to be derived from nutmegs previously deprived of most of their volatile oil by distillation. An artificial preparation is sometimes sold for the genuine oil. It is made by mixing various fatty matters, such as suet, palm oil, spermaceti, wax, &c., adding some colouring substance, and giving flavour to the mixture by the volatile oil.

Mace (Macis, *U. S.*) is in the shape of a flat membrane irregularly slit, smooth, soft, flexible, of a reddish or orange-yellow colour, and an odour and taste resembling those of nutmeg. It contains, according to M. Henry, a volatile oil in small quantity; a fixed oil, odorous, yellow, soluble in ether, insoluble in boiling alcohol; another fixed oil, odorous, red, soluble in alcohol and ether in every proportion; a peculiar gummy matter, analogous to amidin and gum, constituting one-third of the whole, and a small proportion of ligneous fibre. Mace yields a volatile oil by distillation, and a fixed oil by pressure. Neumann found the former heavier than water. The latter is less consistent than the fixed oil of nutmeg. Mace is inferior when it is brittle, less than usually divided, whitish or pale-yellow, or with little taste and smell.

Medical Properties and Uses. Nutmeg unites, with the medicinal properties

* A few years since, attention was called to a California product, derived from *Torreya Californica*, and, from its resemblance to the fruit of the Myristica, called *California nutmeg*. It is, however, quite distinct in its characters from the true nutmeg, and cannot be substituted for it. At the same time a variety of nutmeg appeared in our markets, which was at first supposed to be the California product referred to; but, on examination by Prof. Jos. Carson, was found to be the variety of drug mentioned in the text as the male or wild nutmeg, and to be wholly distinct from the fruit of the Torreya. (*Am. Journ. of Pharm.*, xxvi. 247 and 499.)—*Note to the eleventh edition.*

† A process for obtaining it by means of *bisulphuret of carbon* has been proposed by M. Lepage, of Gisors, in France, and has received the sanction of the Society of Pharmacy of Paris. It consists in treating the nutmeg, thoroughly comminuted, with three times its weight of the liquid referred to, well rectified, agitating the mixture frequently for 24 hours, expressing, repeating the process with two parts only of the menstruum, mixing the products of the two macerations, filtering in a covered vessel, and then distilling off the sulphuret, at a temperature of 160°, until the residue is entirely deprived of the menstruum. (*Journ. de Pharm.*, 3e sér., xxxi. 28.)—*Note to the twelfth edition.*

of the ordinary aromatics, considerable narcotic power. In the quantity of two or three drachms, it has been known to produce stupor and delirium; and dangerous if not fatal consequences are said to have followed its free use in India. It is employed to cover the taste or correct the operation of other medicines, but more frequently as an agreeable addition to farinaceous articles of diet, and to various kinds of drink in cases of languid appetite and delicate stomach. It is usually given in substance, and is brought by grating to the state of a powder. *Mace* possesses properties essentially the same with those of nutmeg; and, like that medicine, has been known, when taken in excess, to produce alarming sensorial disturbance. (G. C. Watson, *Prov. Med. and S. Journ.*, Jan 26, 1848.) It is, however, less used as a medicine. The dose of either is from five to twenty grains. As the virtues of nutmeg depend chiefly if not exclusively on the volatile oil, the latter may be substituted, in the dose of two or three drops. The expressed oil is occasionally used as a gentle external stimulant, and is an ingredient in the *Emplastrum Picis* of the British Pharmacopœia.

The ancients were wholly unacquainted with the nutmeg; and Avicenna is said to be the first author by whom it is noticed.

Myrrh.

The concrete juice of Balsamodendron Myrrha. *U. S.* A gum-resinous exudation from the stem. *Br.*

Myrrhe, *Fr., Germ.;* Mirra, *Ital., Span.;* Murr, *Arab.;* Bowl, *Hindoost.*

Though myrrh has been employed from the earliest times, the plant which yields it was not determined till quite recently. The *Amyris Kataf* of Forskhal, seen by that traveller in Arabia, was supposed by him to be the myrrh tree, but without sufficient proof. Afterwards Ehrenberg met on the frontiers of Arabia Felix with a plant, from the bark of which he collected a gum-resin precisely similar to the myrrh of commerce. From specimens of the plant taken by Ehrenberg to Germany, Nees von Esenbeck referred it to the genus Balsamodendron of Kunth, and named it *Balsamodendron Myrrha.* This genus was formed by Kunth from *Amyris*, and includes the *Amyris Kataf* of Forskhal, which may possibly also produce a variety of myrrh. The new genus differs from *Amyris* chiefly in having the stamens beneath instead of upon the germ. It was not thought by De Candolle sufficiently distinct.

Balsamodendron Myrrha. Fée, *Cours. d'Hist. Nat. Pharm.* i. 641; Carson, *Illust. of Med. Bot.* i. 28, pl. 20. This is a small tree, with a stunted trunk, covered with a whitish-gray bark, and furnished with rough abortive branches terminating in spines. The leaves are ternate, consisting of obovate, blunt, smooth, obtusely denticulate leaflets, of which the two lateral are much smaller than the one at the end. The fruit is oval-lanceolate, pointed, longitudinally furrowed, of a brown colour, and surrounded at its base by the persistent calyx. The tree grows in Arabia Felix, in the neighbourhood of Gison, in dwarfish thickets, interspersed among the Acaciæ and Euphorbiæ. The juice exudes spontaneously, and concretes upon the bark.

Formerly the best myrrh was brought from the shores of the Red Sea by way of Egypt and the Levant, and hence received the name of *Turkey Myrrh;* while the inferior qualities were imported from the East Indies, and commonly called *India Myrrh.* These titles have ceased to be applicable; as myrrh of all qualities is now brought from the East Indies, whither it is carried from Arabia and

the north-eastern coast of Africa. Aden in the former region, and Berbera in the latter, would appear, from the statements of Mr. James Vaughan, to be the chief entrepots of the trade. (*Pharm. Journ.*, xii. 226.) Great quantities are collected on the African coast, near the mouth of the Red Sea, whence it is taken to Aden. (*Ibid.*, Oct. 1859, p. 217.) It is usually imported in chests containing between one and two hundred weight Sometimes the different qualities are brought separate; sometimes more or less mingled. Only the best kind should be selected for medical use.

Properties. Myrrh is in small irregular fragments or tears, or in larger masses, composed apparently of agglutinated portions differing somewhat in their shade of colour. The pieces are exceedingly irregular in shape and size, being sometimes not larger than a pea, and sometimes, though rarely, almost as large as the fist. They are often powdery upon the surface. When of good quality, myrrh is reddish-yellow or reddish-brown and translucent, of a strong peculiar somewhat fragrant odour, and a bitter aromatic taste. It is brittle and pulverizable, presenting, when broken, a shining surface, which in the larger masses is very irregular, and sometimes exhibits opaque whitish or yellowish veins. In powder it is of a light-yellowish colour. Under the teeth it is at first friable, but soon softens and becomes adhesive. It is inflammable, but does not burn vigorously, and is not fusible by heat. Its sp. gr. is stated at 1·36. The inferior kind, commonly called *India myrrh*, is in pieces much darker than those described, more opaque, less odorous, and often abounding with impurities. We have seen pieces of India myrrh enclosing large crystals of common salt; as if the juice might have fallen from the tree, and concreted upon the ground where this mineral abounds. Pieces of *bdellium*, and other gummy or resinous substances of unknown origin, are often mixed with it. Among these is a product which may be called *false myrrh*. It is in irregular pieces, of a dirty reddish-brown colour, a vitreous brownish-yellow fracture, semitransparent, of a faint odour of myrrh, and a bitter balsamic taste. Myrrh is best purchased in mass; as in powder it is liable to adulterations not easily detected.

Myrrh is partially soluble in water, alcohol, and ether. Triturated with water it forms an opaque yellowish or whitish emulsion, which deposits the larger portion upon standing. Its alcoholic tincture is rendered opaque by the addition of water, but throws down no precipitate. According to Neumann, alcohol and water severally extract the whole of its odour and taste. By distillation a volatile oil rises, having the peculiar flavour of myrrh, and leaving the residue in the retort simply bitter. The gum-resin is soluble in solutions of the alkalies, and, when triturated with them in a crystalline state, forms a tenacious liquid. Hence carbonate of potassa may be used to facilitate its suspension in water. Braconnot found 2·5 per cent. of volatile oil, 23 of a bitter resin, 46 of soluble, and 12 of insoluble gum. (*Ann. de Chim.*, lxvii. 52.) Pelletier obtained 34 per cent. of resin, with a small proportion of volatile oil, and 66 of gum. A more recent analysis by Ruickoldt gave 2·183 per cent. of volatile oil, 44·760 of resin, 40·818 of gum or arabin, 1·475 of water, and 3·650 of carbonate of lime and magnesia, with some gypsum and sesquioxide of iron. The resin, which he calls *myrrhin*, is neuter, but becomes acid when kept for a short time in fusion. In the latter state, M. Ruickoldt proposes to call it *myrrhic acid*. (*Archiv. der Pharm.*, lxi. 1.) According to MM. Bley and Diesel, myrrh containing little volatile oil always has an acid reaction, which they ascribe to the oxidation of the oil. They found formic acid in the specimen examined by them. (*Ibid.*, xliii. 304.)

The same writers give, as a test of myrrh, the production of a transparent dirty-yellow liquid with nitric acid; while false myrrh affords a bright-yellow solution in the same fluid, and bdellium is not dissolved, but becomes whitish and opaque. (*Am. Journ. of Pharm.*, xviii. 228.) According to M. Righini, if powdered myrrh, rubbed for 15 minutes with an equal weight of muriate of ammonia, and 15 times its weight of water gradually added, dissolve quickly and entirely, it may be considered pure. (*Journ. de Chim. Méd.*, 1844, p. 33.)

Medical Properties and Uses. Myrrh is a stimulant tonic, with some tendency

to the lungs, and perhaps to the uterus. Hence it is employed as an expectorant and emmenagogue in debilitated states of the system, in the absence of febrile excitement or acute inflammation. The complaints in which it is usually administered are chronic catarrh, phthisis pulmonalis, other pectoral affections in which the secretion of mucus is abundant but not easily expectorated, chlorosis, amenorrhœa, and the various affections connected with this state of the uterine function. It is generally given combined with chalybeates or other tonics, and in amenorrhœa very frequently with aloes. It is used also as an application to spongy gums, the aphthous sore-mouth of children, and various kinds of unhealthy ulcers. The dose is from ten to thirty grains, and may be given in the form of powder or pill, or suspended in water, as in the famous antihectic mixture of Dr. Griffith, which has become officinal by the name of *Mistura Ferri Composita*. The infusion is also sometimes given, and an aqueous extract has been recommended as milder than myrrh in substance. The tincture is used chiefly as a local application.

A *plaster of myrrh* is made by rubbing together powdered myrrh, camphor, and balsam of Peru, of each an ounce and a half, then adding the mixture to 32 ounces of lead plaster previously melted, and stirring well until the plaster thickens on cooling. It is then to be formed into rolls. This plaster may be employed in all cases where a gentle and long-continued rubefacient effect is desired.

NECTANDRA. *U. S.*

Nectandra. Bebeeru Bark.

The bark of Nectandra Rodiei (*Schomburg*). *U. S.*

Off. Syn. NECTANDRÆ CORTEX. *Bebeeru Bark.* The bark of Nectandra Rodiæi (*Schomburgk*); the Greenheart tree. *Br.*

NECTANDRA. *Sex. Syst.* Dodecandria Monogynia.—*Nat. Ord.* Lauraceæ.

Gen. Ch. Flowers hermaphrodite. *Calyx* six-parted, rotate, the three outer segments somewhat broader. *Stamens* twelve, in four series, the nine outer fertile; the anthers of the first and second series turned inwards, of the third outwards, all ovate, sub-sessile, four-celled. *Ovary* one-celled, with one ovule. *Style* short. *Stigma* short, truncated. *Berry* one-seeded, partly immersed in the tube of the calyx. *Endlicher.*

Nectandra Rodiæi. Schomburgk; *Hooker's Lond. Journ. of Bot.*, Dec. 1844, p. 624. The *bebeeru*, *bibiru*, or *sipiri*, as it has been differently named, is a tree sixty feet or more in height, branching near the top, with a smooth, ash-gray bark. The leaves, which are five or six inches long by two or three in breadth, are nearly opposite, coriaceous, oblong-elliptical, shortly acuminate, smooth, shining, and obscurely reticulate on the upper surface. The flowers are yellowish-white, in axillary panicles, much shorter than the leaves, and few-flowered. The fruit is a large, obovate or obcordate, somewhat compressed berry, of the size of a small apple, with a single seed about as large as a walnut. The tree inhabits Guiana and neighbouring regions of South America, where the wood is used in ship-building, under the name of *greenheart*. It received its specific name of *Rodiei* from Sir Robert Schomburg, in honour of Dr. Rodie, by whom it was first described. Though the fruit is very bitter, its seeds yield a starch which is said to be used as food by the Indians. The bark is officinal.

Properties. This is in large, flat, heavy pieces, from one to two feet long, from two to six inches broad, and three or four lines thick, with a rough and somewhat fibrous fracture, of a grayish-brown colour on its outer surface, and a dark-cinnamon on the inner. It has an intensely bitter, somewhat astringent taste. Analyzed by Dr. Maclagan, of Edinburgh, it was found to contain tannic acid of the kind that precipitates the salts of iron green, resin, gum, sugar, albu-

men, fibrin, various salts, and two peculiar alkaloids, named respectively *bebeerin* (bebeeria) and *sipeerin* (sipeeria). In the seeds, besides the foregoing principles, Dr. Maclagan found 53 per cent. of starch, and a peculiar white, crystalline, volatile acid, which he named *bebeeric acid*. The alkaloids are extracted together from the bark, in the form of impure sulphate, by a process similar to that for preparing sulphate of quinia. This preparation is known as the *commercial sulphate of bebeerin*. The sipeerin, which Dr. Maclagan believed to be a distinct alkaloid in the bark, he was afterwards induced to consider as the result of oxidation of bebeeria. (Pereira, *Mat. Med.*)

Bebeeria, which, in accordance with the ordinary nomenclature of the alkaloids, should be called *nectandria*, was obtained pure by Messrs. Maclagan and Tilley by the following process. The impure sulphate is dissolved in water, and precipitated by ammonia. The precipitate, mixed with an equal weight of recently precipitated oxide of lead, and dried, is treated with absolute alcohol, which, being evaporated, leaves the two alkaloids in the form of a translucent resinoid mass. The bebeeria is separated by means of ether, which yields it by evaporation. Another process is to dissolve the precipitate obtained by ammonia, previously washed, in diluted acetic acid, add acetate of lead, precipitate by potassa, exhaust the precipitate by strong ether, evaporate the ether to the consistence of a syrup, dissolve the residue in absolute alcohol, and pour the solution gradually into water. A flocculent deposit is formed, which, when washed and dried, is the alkaloid in question. Bebeeria is pale-yellow, amorphous, of a resinous aspect, inodorous, very bitter, very slightly soluble in water, freely soluble in alcohol and ether, fusible at 356°, inflammable, and of an alkaline reaction. It forms uncrystallizable salts with the acids. Its formula is differently given $C_{35}H_{29}NO_6$, and $C_{38}H_{21}NO_6$.

Sipeeria (*sipeerin*) is left after the separation of the bebeeria by ether in the foregoing processes. This also is amorphous, very sparingly soluble in water, freely soluble in alcohol, but differing from bebeeria in being insoluble in ether.

Medical Properties and Uses. Nectandra is tonic, somewhat astringent, and febrifuge, resembling cinchona in its virtues, though much inferior, at least in antiperiodic power. It has generally been employed in the form of the impure sulphate, and sometimes with great asserted success, in the treatment of intermittent and remittent fevers. Dr. Rodie recommended it so early as 1834; but it did not attract general attention until brought into notice by Dr. Douglas Maclagan, of Edinburgh, who published a number of observations, tending to prove its possession of valuable antiperiodic properties. Others afterwards confirmed his statements in its favour, and it was hoped that a substitute had been found for the alkaloids of Peruvian bark; but the more recent published accounts by M. Becquerel, of France (*Journ. de Pharm.*, 3e sér., xx. 439), of Dr. Wm. Pepper, of Philadelphia (*Am. Journ. of Med. Sci.*, N. S., xxv. 13), and of Dr. E. D. Dailey, of Smyrna, Delaware (*Med Exam.*, N. S., ix. 557), show satisfactorily that, though frequently successful, it often fails, and cannot be relied on as a substitute for quinia. From a scruple to a drachm may be given between the paroxysms, in doses of two grains. Prof. A. P. Merrill has employed the sulphate with advantage in menorrhagia, in the dose of five grains. (*N. Y. Journ. of Med.*, N. S., xv. 433; from the *Memphis Med. Recorder.*)

The *impure sulphate* (*commercial sulphate*) *of bebeeria* may be prepared by first boiling the powdered bark with a solution of carbonate of soda, to remove the tannic acid and colouring matter, and afterwards with water acidulated with sulphuric acid, which extracts the alkaloids in the form of sulphates. The solution is then filtered, the alkaloid precipitated by carbonate of soda, the precipitate dissolved and neutralized with dilute sulphuric acid, the solution, decolorized with animal charcoal, then concentrated, filtered, and finally evaporated in open vessels, with a gentle heat. Thus obtained, the sulphate is fit for medical use, though it is not pure, containing sipeeria, a little sulphate of lime, and colouring matter. It is in brownish, thin, shining scales, which become yellow in powder. It is freely soluble in alcohol, and sparingly in water, but

is readily dissolved in the latter if acidulated. It may be given in the form of pill, or of solution in water acidulated with sulphuric acid, one minim of the officinal diluted or aromatic sulphuric acid being added for each grain of the sulphate. The dose is from two to five grains.

A new application of the sulphate of bebeeria has recently been made by Dr. A. P. Merrill, who has found it very useful in various uterine diseases, as dysmenorrhœa, menorrhagia, leucorrhœa, and all other conditions accompanied with enlargement and congestion of the uterus and its appendages. It has proved useful also in disorders of the kidneys and bladder and blenorrhœal discharges. (*N. Y. Med. Record*, March 1, 1867, p. 7.)

The pure sulphate may be readily prepared by dissolving bebeeria, obtained as above directed, in water with sulphuric acid to neutralization, and evaporating the solution.

NUX VOMICA. *U. S., Br.*

Nux Vomica.

The seed of Strychnos nux vomica. *U. S.* The seeds. *Br.*

Noix vomique, *Fr.;* Krähenaugen, Brechnüsse, *Germ.;* Noce vomica, *Ital.*; Nuez vomica, *Span.*

Strychnos. *Sex. Syst.* Pentandria Monogynia. — *Nat. Ord.* Apocynaceæ. *Gen. Ch. Corolla* five-cleft. *Berry* one-celled, with a ligneous rind. *Willd.*

Strychnos Nux vomica. Willd. *Sp. Plant.* i. 1052; Woodv. *Med. Bot.* p. 222, t. 79. This tree is of a moderate size, with numerous strong branches, covered with a smooth, dark-gray bark. The young branches are long, flexuous, smooth, and dark-green, with opposite, roundish-oval, entire, smooth, and shining leaves, having three or five ribs, and short footstalks. The flowers are small, white, funnel-shaped, and in terminal corymbs. The fruit is a round berry, about as large as an orange, with a smooth, yellow or orange-coloured, hard, fragile rind, and many seeds embedded in a juicy pulp.

The tree is a native of the East Indies, growing in Bengal, Malabar, on the Coromandel Coast, in Ceylon, in many islands of the Indian Archipelago, in Cochin-China, and other neighbouring countries. The wood and root are very bitter, and are employed in the East Indies for the cure of intermittents. The *radices colubrinæ* and *lignum colubrinum* of the older writers, long known in Europe as narcotic poisons, have been ascribed to this species of Strychnos, under the impression that it is identical with *Strychnos Colubrina*, to which Linnæus refers them. They have been ascertained by Pelletier and Caventou to contain a large quantity of strychnia. The bark is said by Dr. O'Shaughnessy to answer exactly to the description given by authors of the *false angustura*, and, like that, to contain a large quantity of brucia. The identity of the two barks has been confirmed by Dr. Pereira, from a comparison of specimens. (See *Angustura.*) The seeds are the only officinal portion.

These are circular, about three-quarters of an inch in diameter, and two lines in thickness, flat, or slightly convex on one side, and concave on the other. They are thickly covered with fine, silky, shining, ash-coloured or yellowish-gray hairs, attached to a thin fragile coating, which closely invests the interior nucleus or kernel. This is very hard, horny, usually whitish and semitransparent, sometimes dark-coloured and opaque, and of very difficult pulverization. The powder is yellowish-gray, and has a faint sweetish odour. The seeds are destitute of odour, but have an acrid, very bitter taste, which is much stronger in the kernel than in the investing membrane. They impart their virtues to water, but more readily to diluted alcohol. Nux vomica has been analyzed by several chemists, but most accurately by Pelletier and Caventou, who discovered in it two alkaline principles, *strychnia* and *brucia*, united with a peculiar acid which they named *igasuric*. Its other constituents are a yellow colouring matter, a concrete oil, gum, starch, bassorin, a small quantity of wax, and, according to Mr. J.

M. Maisch, several earthy phosphates. (*Am. Journ. of Pharm.*, Nov. 1860, p. 524.) M. Desnoix has announced the discovery of another alkaloid, which he denominates *igasuria*; and M. Shutzenberger, in examining specimens of igasuria, separated nine alkaloids, each having a distinct composition, and all probably derived from brucia by oxidation under vital influences. These alkaloids are the active principles of nux vomica.

Strychnia was discovered by Pelletier and Caventou, A. D. 1818, both in the nux vomica and bean of St. Ignatius, and received its name from the generic title of the plants (*Strychnos*) to which these two products belong. According to these chemists, it exists much more abundantly in the bean of St. Ignatius than in the nux vomica, the former yielding 1·2 per cent., the latter only 0·4 per cent. of the alkaloid. For an account of its properties and mode of preparation, see *Strychnia*, in *Part* II. This alkaloid is stated to exist still more largely in the seeds of another species, the *Strychnos Tiute*, which is a native of Java. In the *Zeitschrift für Chemie* (A. D. 1866), M. Bernelot-Moens states that the seeds of this species, when dry, contain 1·469 per cent. of strychnia, with only traces of brucia. (*Am. Journ. of Pharm.*, Nov. 1866, p. 506.)

Brucia was discovered by Pelletier and Caventou, first in the bark called *false angustura*, in combination with gallic acid, and subsequently associated with strychnia in the form of igasurates, in the nux vomica and bean of St. Ignatius. It is crystallizable, and its crystals are said to contain 18·41 per cent. of water. It is without smell, but of a permanent, harsh, very bitter taste; soluble in 850 parts of cold, and 500 of boiling water; very soluble in alcohol, whether hot or cold; but insoluble in ether and the fixed oils, and only slightly dissolved by the volatile oils. It is permanent in the air, but melts at a temperature a little above that of boiling water, and on cooling congeals into a mass resembling wax. According to Mr. Wm. A. Guy, who has carefully experimented on the volatility of various proximate principles, it melts at 240°, and sublimes at 400°, changing colour, and depositing carbon. (*Pharm. J. and Trans.*, Feb. 1868, p. 375.) It forms crystallizable salts with the acids. Concentrated nitric acid produces with brucia or its salts an intense crimson colour, which changes to yellow by heat, and upon the addition of protochloride of tin becomes violet. These effects serve to distinguish brucia from strychnia, and, if produced with the latter alkaloid, evince the presence of the former. According to MM. Larocque and Thibierge, chloride of gold produces, with solutions of the salts of brucia, precipitates at first milky, then coffee-coloured, and finally chocolate-brown. (*Journ. de Chim. Méd.*, Oct. 1842.) Brucia is analogous in its operation to strychnia, but possesses, according to M. Andral, only about one-twelfth of its strength, when the latter principle is entirely pure. It is therefore seldom employed. It may be procured from false angustura bark, in a manner essentially the same with that in which strychnia is procured from nux vomica; with this difference, that the alcoholic extract, obtained from the precipitate produced by lime or magnesia, should be treated with oxalic acid, and subsequently with a mixture of rectified alcohol and ether, which takes up the colouring matter, leaving the oxalate of brucia. This is decomposed by magnesia, and the brucia is separated by alcohol, which, by spontaneous evaporation, yields it in the state of crystals. According to Dr. Fuss and Professor Erdmann, brucia is nothing more than a compound of strychnia and resin.

Igasuria is found in the mother-waters from which strychnia and brucia have been precipitated by lime. It is strongly bitter; readily crystallizable, with 10 per cent. of water of crystallization; more soluble in water and weak alcohol than the two other alkaloids; reddened by nitric acid even more intensely than brucia; rendered by sulphuric acid at first rose-coloured, and afterwards yellowish and greenish-yellow; dissolved by the diluted acids, which form with it easily crystallizable salts; precipitated from its solution by the alkalies, and redissolved by them in excess, especially by potassa; precipitated yellow by bichloride of platinum, and white by tannic acid; slowly precipitated by iodide of potassium in light reddish-yellow crystals; and thrown down as crystalline

needles by bicarbonate of soda, in the presence of tartaric acid, in which property it resembles strychnia, but differs from brucia. One of its most distinguishing properties is its degree of solubility in water, of which it requires at 212° only 200 parts for solution; while brucia requires 500 parts, and strychnia 2000. M. Desnoix inferred from his experiments on animals that it is intermediate in power between the two other alkaloids of nux vomica.

The nine alkaloids into which Schutzenberger separated igasuria, he distinguished by affixing the letters of the alphabet, as *a* igasuria, *b* igasuria, &c. They may be separated by the agency of hot water, by taking advantage of their different solubility, and their several periods of crystallizing as the solution cools. They are all colourless, crystallizable in needles or tufts, of a persistent bitterness, and almost as energetic as strychnia in their influence on the system. All are coloured red by nitric acid, like brucia, which, moreover, they resemble in their characters, except their greater solubility in water and alcohol. (*Am. Journ. of Pharm.*, Nov. 1858, p. 537; from *Comptes Rendus.*) It is difficult to resist the conjecture that the alkaloids, instead of pre-existing, are formed by changes in the igasuria during the crystallizing process.

As a test for nux vomica, Vielgruth proposes to treat a few grains of the suspected powder with proof spirit, evaporate the tincture to dryness at a heat not exceeding 96°, then add a drop or two of dilute sulphuric acid, and again raise to the heat mentioned. If nux vomica is present, a beautiful carmine-red colour is produced, which disappears in ten or fifteen minutes after cooling, and reappears, but less brightly, on the reapplication of the heat.

Medical Properties and Uses. Nux vomica is very peculiar in its action. In very small doses, frequently repeated, it is tonic, and is said to be diuretic, and occasionally diaphoretic and laxative. When it is given in larger doses, so as to bring the system decidedly under its influence, its action appears to be directed chiefly to the nerves of motion, probably through the medium of the spinal marrow. Its operation is evinced at first by a feeling of weight and weakness, with tremblings in the limbs, and some rigidity on attempting motion. There seems to be a tendency to permanent involuntary muscular contraction, as in tetanus; but at the same time frequent starts or spasms occur, as from electric shocks. These spasms are first brought on by some exciting cause, as by a slight blow or an attempt to move; but, if the medicine is persevered in, they occur without extraneous agency, and are sometimes frequent and violent. In severe cases, there is occasionally general rigidity of the muscles. A sense of heat in the stomach, constriction of the throat and abdomen, tightness of the chest, and retention of urine are frequently experienced, to a greater or less extent, according to the quantity of the medicine administered. It sometimes, also, produces pain in the head, vertigo, contracted pupil, and dimness of vision. Sensations on the surface analogous to those attending imperfect palsy, such as formication, tingling, &c., are often experienced. The pulse is not materially affected, though sometimes slightly accelerated. Strychnia, given to the inferior animals, has been observed strikingly to lessen the bulk of the spleen. In overdoses, the medicine is capable of producing fatal effects. Given to the inferior animals in fatal doses, it produces great anxiety, difficult and confined breathing, retching to vomit, universal tremors, spasmodic action of the muscles, and ultimately violent convulsions. Death is supposed to take place from a suspension of respiration, resulting from a spasmodic constriction of the muscles concerned in the process. Yet it poisons animals which have no lungs. (*Am. Journ. of Med. Sci.*, N. S., xviii. 369.) Upon dissection, no traces of inflammatory action are observable, unless large quantities of the nux vomica have been swallowed, when the stomach appears inflamed. A division of the spinal marrow near the occiput does not prevent the peculiar effects of the medicine, so that the intervention of the brain is not essential. That it enters the circulation, and is brought into contact with the parts upon which it acts, is rendered evident by the experiments of Magendie and others. For further observations on the effects of this poison, and for the modes of obviating them, see *Strychnia* in *Part* II.

Nux vomica has long been employed in India, and was known as a medicine to the Arabian physicians. On the continent of Europe, it has at various times been recommended as an antidote to the plague, and as a remedy in intermittents, dyspepsia, pyrosis, gastrodynia, dysentery, diarrhœa of debility, colica pictonum, worms, mania, hypochondriasis, hysteria, rheumatism, and hydrophobia. It is said to have effectually cured obstinate spasmodic asthma. Its peculiar influence upon the nerves of motion, to which the public attention was first called by Magendie, suggested to M. Fouquier, a French physician, the application of the remedy to paralytic affections, in which he met with great success. Others have subsequently employed it with variable results: but the experience in its favour so much predominates, that it may now be considered a standard remedy in palsy. It is a singular fact, that its action is directed more especially to the paralytic part, exciting contraction in this before it is extended to other muscles. The medicine, however, should be administered with judgment, and never given in cases depending on inflammation or organic lesion of the brain or spinal marrow, until after the removal of the primary affection. It has been found more successful in general palsy and paraplegia than in hemiplegia, and has frequently effected cures in palsy of the bladder, incontinence of urine from paralysis of the sphincter, prolapsus ani, amaurosis, and other cases of partial palsy, and has been employed with asserted success in prolapsus ani, spermatorrhœa, and impotence. Upon the same principles, it is said to have proved useful in obstinate constipation from deficient contractility of the bowels; and is thought to promote the action of cathartics, when added to them in small proportion. It has recently been recommended in neuralgia, chorea, and atonic dropsy, and has been found peculiarly useful in gastralgia, gastro-enteralgia, and other debilitated conditions of the alimentary canal. Dr. D. de Savignac, of the Maritime Hospital of Toulon, has found great advantage from this remedy in a variety of chronic dysentery, which he believes to depend on an affection of the spinal marrow, causing paralysis of the motor nerves supplying the muscular coat of the large intestines, and which is apt to be accompanied with palsy of the limbs. (*Edin. Med. Journ.*, Jan. 1868, p. 657.)

Nux vomica may be given in powder in the dose of five grains, repeated three or four times a day, and gradually increased till its effects are experienced. In this form, however, it is very uncertain; and fifty grains have been given with little or no effect. It is most readily reduced to powder by filing or grating; and the raspings may be rendered finer by first steaming them, then drying them by stove heat, and lastly rubbing them in a mortar. The Edinburgh College directed that the seeds should be first well softened with steam, then sliced, dried, and ground in a coffee-mill. It has been recommended that, before being pulverized, they should be deprived of their exterior coating, which is easily done when they are exposed for a short time to the action of hot water.

The alcoholic extract is more convenient and more certain in its operation. From half a grain to two grains may be given in the form of pill, repeated as above mentioned, and gradually increased. (See *Extractum Nucis Vomicæ.*) The watery extract is comparatively feeble.

Strychnia has recently been much used, and possesses the advantage of greater certainty and uniformity of action. Its effects are precisely similar. With very few exceptions, it is the most violent poison in the catalogue of medicines, and should, therefore, be administered with great caution. The dose is from one-sixteenth to one-twelfth of a grain, repeated twice or three times a day, and gradually increased. Even the quantity mentioned often produces spasmodic symptoms, and these generally occur when the dose is augmented to half a grain three times a day; but in the latter quantity the remedy, if pure, is unsafe. The system is not so soon habituated to its impression as to that of the narcotics generally; so that, after its effects are experienced, it is unnecessary to go on increasing the dose. Strychnia has been applied externally with advantage in amaurosis. It should be sprinkled upon a blistered surface near the temples, in the quantity of from one-fourth to one-half a grain, morning and evening; and the quantity

may be gradually augmented. The best form of administration is that of pill, in consequence of the excessive bitterness of the solution. Strychnia may, however, be given, dissolved in alcohol, or in water by the intervention of an acid.

Brucia may be used, for the same purposes with strychnia, in the dose of one grain twice or three times a day. Dr. Bardsley noticed that the quantity of two grains, three or four times a day, was seldom exceeded without the occurrence of the characteristic effects of the medicine. Magendie found this alkaloid very useful in small doses as a tonic. He employed for this purpose one-eighth of a grain frequently repeated. It is very important, in reference to the dose, that it should contain no strychnia.

OLEA.

Oils.

These are liquid or solid substances, characterized by an unctuous feel, inflammability, and the property of leaving a greasy stain upon paper. They are divided into two classes, the *fixed* and *volatile*, distinguished, as their names imply, by their different habitudes in relation to the vaporizing influence of caloric.

1. OLEA FIXA. *Fixed Oils.*

These are sometimes termed *expressed oils*, from the mode in which they are procured. Though existing in greater or less proportion in various parts of plants, they are furnished for use exclusively by the fruit; and, as a general rule, are most abundant in the dicotyledonous seeds. They are obtained either by submitting the bruised seeds to pressure in hempen bags, or by boiling them in water, and skimming off the oil as it rises to the surface. When pressure is employed, it is customary to prepare the seeds for the press by exposing them to a moderate heat, so as to render the oil more liquid, and thus enable it to flow out more readily. Another mode of extracting certain oils is by means of liquids having the power of dissolving them. This method, however, is comparatively little used, because generally less easy of application and more expensive. Near Berlin, in Germany, however, is an establishment where the oil existing in various grains, as the colza, flaxseed, and mustard, is extracted by means of the sulphide of carbon, on a large scale. For the details of the process the reader is referred to the *Amer. Journal of Pharmacy* (Nov. 1868, p. 549).

The consistence of the fixed oils varies from that of tallow to perfect fluidity; but by far the greater number are liquid at ordinary temperatures. They are somewhat viscid, transparent, and usually of a yellowish colour, which disappears when they are treated with animal charcoal. When pure they have little taste or smell. They are lighter than water, varying in specific gravity from 0·913 to 0·936. (*Berzelius.*) They differ very much in their point of congelation; olive oil becoming solid a little above 32° F., while linseed oil remains fluid at 4° below zero. They are not volatilizable without decomposition. At about 600° they boil, and are converted into vapour, which, when condensed, is found to contain, besides other products, a large proportion of oleic and margaric acids, together with benzoic acid, sebacic acid proceeding from the decomposition of the olein, and the vapours of *acrolein*, a highly volatile liquid resulting from the decomposition of glycerin, upon which the fumes of oils depend mainly for their irritating effects on the eyes and nostrils. Exposed to a red heat, in close vessels, they yield, among other products of the destructive distillation of vegetables, a large quantity of the combustible compounds of carbon and hydrogen. Heated in the open air they take fire, burning with a bright flame, and producing water and carbonic acid. When kept in air-tight vessels, they remain unchanged for a great length of time; but, exposed to the atmosphere, they attract oxygen, and ultimately become concrete. Some, in

drying, lose their unctuous feel, and are converted into a transparent, yellowish, flexible solid. These are called *drying oils*. Others, especially such as contain mucilaginous impurities, become rancid, acquiring a sharp taste and unpleasant smell. This change is owing to the formation of an acid, from which the oil may be freed by boiling it for a short time with hydrate of magnesia and water.* The fixed oils are insoluble in water, but are miscible with that fluid by means of mucilage, forming mixtures which are called emulsions. They are in general very sparingly soluble in alcohol, but readily dissolved by ether, which serves to separate them from other vegetable proximate principles. By the aid of heat they dissolve sulphur and phosphorus. Chlorine and iodine are converted by them into muriatic and hydriodic acids, which, reacting upon the oils, increase their consistence, and ultimately render them as hard as wax. If to one of the fixed oils be added one-tenth of its volume of chloride of sulphur, a reaction speedily takes place, attended with an elevation of temperature and the escape of muriatic acid gas, and followed immediately by solidification of the oil, which is wholly converted into a firm elastic substance, bearing considerable resemblance to caoutchouc. (*Journ. de Pharm.*, Fev. 1859, p. 97.) The stronger acids decompose them, giving rise, among other products, to oleic and margaric acids. Boiled with diluted nitric acid, they are converted into malic and oxalic acids, besides other substances usually resulting from the action of this acid upon vegetable matter. Several acids are dissolved by them without producing any sensible change. They combine with salifiable bases; but at the moment of combination undergo a change, by which they are resolved into a peculiar substance called glycerin, and into the oleic and margaric or other fatty acids, which unite with the base employed. The compounds of these acids with potassa and soda are called soaps. (See *Sapo* and *Emplastrum Plumbi.*) By the addition of one part of carbonate of potassa or of soda, 160 parts of oil may be brought with distilled water into the form of an emulsion. The potassa and soda soaps, and the alkaline sulphurets have a similar effect; but not the bicarbonates. The fixed oils also serve as good vehicles for various metallic bases and subsalts, which form soaps to a certain extent soluble in the oil, and thus become less irritant to the tissues. Oils thus impregnated may, like the pure oils, be brought to the state of emulsion with water, for convenient administration, by the addition of a small proportion of carbonate of potassa. (Jeannel et Monsel, *Revue Pharm.*, 1857, p. 48.) The fixed oils dissolve many of the organic alkalies, the volatile oils, resin, and other proximate principles of plants. The alkaloids are more readily dissolved in them by being first combined with oleic acid; the oleates being more soluble than the alkaloids themselves. (Attfield, *Pharm. Journ.*, March,

* Results of experiments by M. S. Cloes show that the phenomena of the oxidation of the oils in the atmosphere are less simple than originally supposed by De Saussure, namely, that oxygen is absorbed and an equivalent quantity of carbonic acid is evolved. On the contrary, the quantity of carbonic acid produced represents but a fourth of the carbon eliminated; the remainder forming with hydrogen and oxygen various volatile compounds, which, when collected, have a suffocating smell, and among which were recognised acetic acid, acrylic acid, and a little acrolein. (*Journ. de Pharm. et de Chim.*, 4e sér., ii. 287, A. D. 1865.)

M. Cloes has made investigations also in relation to the influence of light in promoting oxidation, and obtained some curious results. The general influence of light is very great, as oils undergo comparatively little change in the dark for a long time; though, in relation to some of them, the change is at length as great as under the light. Thus, while the oil of poppies has in thirty days increased about 50 per cent. in weight under colourless light, and has gained only a 5000th in the dark; yet, at the end of 150 days, the weight in the former condition was rather lessened than augmented, and in the latter, or in the dark, had increased 64 per cent. The effect of the different coloured rays is also very different. The change is at first most rapid under the white light, less so under the blue, and much less under the red, yellow, and green, being least of all with the green; but, with the advance of time, the blue overtakes and even passes the white, and at the end of three or four months all are about equal in effect. Heat also accelerates the concretion of the oils, by favouring their oxidation; and the same effect is produced by introducing into the unchanged oil a little which has already been altered by exposure to the air. The oxidation of an oil may be very greatly hastened in this way without the aid of heat. (*Ibid.*, p. 345.)—*Note to the thirteenth edition.*

1863, p. 308.) According to Buignet, they are, with very few exceptions, indifferent to polarized light; of all those used in medicine, the only exceptions being the liver-oils of the ray and dog-fish, which have a very feeble left rotatory power, and castor oil, which is decidedly dextrogyrate. (*Journ. de Pharm.*, Octob. 1861, p. 264.)

The fixed oils, whether animal or vegetable, in their natural state, consist of at least two distinct oleaginous ingredients, one liquid at ordinary temperatures, and the other concrete. The liquid is a distinct proximate principle called *olein;* the concrete consists of *stearin* or *margarin*, the former being found most largely in animal, the latter in vegetable oils or fats, and the two not unfrequently existing together in the same oil. But several oils have peculiar constituents, differing in properties from either margarin or stearin, and specially named according to the substance containing them; as, *palmitin* in palm oil, *butyrin* in butter, &c. As the most frequent of these proximate constituents of the fixed oils, and existing in many different oleaginous substances, olein, margarin, and stearin merit a special notice. Preliminarily, however, to their individual consideration, it will be proper to refer to the existing views in relation to their nature and composition generally.

It is supposed that these oleaginous principles are of the nature of salts, consisting severally of an acid combined with a substance called glycerin, which acts the part of a base. When, therefore, one of them is treated with an alkaline solution, it is decomposed; its acid uniting with the alkali to form soap, and the glycerin being set free. The analogy between these fatty salts and those consisting of inorganic ingredients may be carried still further; as glycerin is supposed to be, like the inorganic bases, an oxide, and to consist of a compound radical called *glyceryl* (C_6H_7) with five eqs. of oxygen, united with one eq. of water; its formula being $C_6H_7O_5+HO$. The fatty acids, existing in these oleaginous salts, are named severally from the oily principles containing them. Thus, the acid of olein is called *oleic acid*, that of stearin *stearic acid*, and that of margarin *margaric acid*. It must be admitted that this view of the nature of the oily principles was at first received with some hesitation; and many supposed that, when an alkali with water was made to act on the oils, the resulting fatty acids and glycerin were generated by the reactions set on foot between the oil and water, and did not pre-exist in the oil. In favour of this view was the fact, that the presence of water was necessary to the change. But this is explained by the supposition that the oxide of glyceryl cannot exist separately unless combined with water, the presence of which, therefore, is necessary to detach it from its combination with the fatty acid in the oils. Moreover, the received view has been synthetically confirmed; for M. Berthelot has succeeded in combining glycerin with various acids, forming salts, and among others with oleic, stearic, and margaric acids, thus reconstructing olein, stearin, and margarin out of their constituents.

Olein. Elain. Liquid Principle of Oils. It is extremely difficult to obtain olein pure. Being the liquid menstruum which, in most oils, holds the concrete principles in solution, it has for the latter an affinity which retains portions of them with a tenacity not easily overcome. As ordinarily procured, therefore, olein contains more or less of margarin or stearin, or both. In this somewhat impure state, it is obtained either by the agency of alcohol or by expression. When one of the oils, olive oil, for example, is dissolved in boiling alcohol, the solution, on cooling, deposits the concrete principles, still retaining the olein, which it yields upon evaporation. The other method consists in compressing one of the solid fats, or of the liquid oils rendered concrete by cold, between folds of bibulous paper, which absorb the olein, and give it up afterwards by compression under water. Olein is a liquid of oily consistence, becoming concrete at 20° F., colourless when pure, with little odour and a sweetish taste, insoluble in water, soluble in boiling alcohol and ether, and composed of carbon, hydrogen, and oxygen. These elements are believed to be so combined as to form a salt, consisting, according to Berthelot, of one eq. of glycerin $C_6H_7O_5$ and

three eqs of oleic acid $3(C_{36}H_{33}O_3) = C_{114}H_{105}O_{12}$, the *teroleate of glycerin*, or *triolein* of Berthelot.* By reaction with nitric acid, olein is converted into a deep-yellow, butyraceous mass. If this be treated with hot alcohol, a deep orange-red oil is dissolved, and a peculiar fatty matter remains called *elaïdin*. This is white, fusible at 97°, insoluble in water, readily soluble in ether, and supposed to be isomeric with olein. It is resolved by saponification with the alkalies into *elaïdic acid* and glycerin; and is, therefore, *elaïdate of glycerin*. It is now generally thought that olein, as obtained from different oils, is not precisely identical in properties; and a distinct compound is recognised, consisting of one eq. of glycerin $C_6H_7O_5$ and one of oleic acid without water $C_{36}H_{33}O_3 = C_{42}H_{40}O_8$, the *oleate of glycerin*, or *monolein* of Berthelot.

Stearin. This exists abundantly in tallow and other animal fats. It may be obtained by treating the concrete matter of lard, free from olein, by cold ether so long as anything is dissolved. The margarin is thus taken up, and stearin remains. A better method is to dissolve suet in heated oil of turpentine, allow the solution to cool, submit the solid matter to expression in unsized paper, repeat the treatment several times, and finally dissolve in hot ether, which deposits the stearin on cooling. This is concrete, white, opaque in mass, but of a pearly appearance as crystallized from ether, pulverizable, fusible at about 143°, soluble in boiling alcohol and ether, but nearly insoluble in those liquids cold, and quite insoluble in water. It consists of glycerin and stearic acid; but there are several varieties of it, having different points of fusion, and somewhat differing in composition. Besides the natural stearin, which appears to consist of four eqs. of stearic acid and one of glycerin, Berthelot obtained two others by heating glycerin with stearic acid; one of them with one eq. of each of its components, the other with two of the acid and one of the base.

Margarin. This is obtained by treating the concrete matter of oil, previously deprived of olein, with cold ether, and allowing the liquid to evaporate; or by boiling a mixture of stearin and margarin with ether, which dissolves both, but deposits the former on cooling, and yields the latter upon subsequent evaporation. It resembles stearin closely, differing mainly in its lower melting point, in being soluble in cold ether, and in yielding margarates on saponification. The natural margarin is stated to consist of four eqs. of margaric acid and one of glycerin. Another has been produced artificially which is considered as a *monomargarin*, consisting of one eq. of each of its components.

As stated above, there is some reason to consider olein, stearin, and margarin, as being rather representatives of sets of proximate principles, than as quite distinct and peculiar; and this appears to have been the impression of Berzelius. It is possible, as may be inferred from the observations of Berthelot, that the several oleins, stearins, and margarins may differ in the proportion in which the acid constituent combines with the glycerin.†

* Oleic acid has been proposed as a solvent of the vegetable alkaloids for external use. Its supposed advantages are that it dissolves these principles more freely than the oils themselves, and that the compounds it forms with them would probably find ready entrance into the system. It is not, however, in general use. (See *Am. Journ. of Pharm.*, xxvii. 72.)

† Some interesting results in relation to the fixed oils were obtained by MM. Pelouze and Boudet, and published in the *Journ. de Pharm.*, xxiv. 385. According to these chemists, the variable fusibility of the margarin and stearin of fixed oils, which has induced some chemists to believe that they are severally not entirely identical as obtained from different oils, is owing to the existence of definite combinations of margarin and stearin respectively with olein; and each of these principles, in a state of purity, is probably the same from whatever source derived, whether from vegetable or from animal oils. Thus they found the same margarin in palm oil and in human fat. But there appear to be two distinct kinds of olein; one existing in the *drying oils*, as linseed oil, the oil of poppies, &c.; the other in the oils which are not drying, as olive oil, almond oil, human fat, and lard. These two forms of olein are different in their solubility in different menstrua, and in the circumstances that one is drying and the other not so, that one remains liquid under the action of nitric acid, while the other is converted by it into a solid substance called *elaïdin*, and finally that the former contains much less hydrogen than the latter. Besides, the oleic acid formed in the process of saponification from these two kinds of olein is decidedly different; inasmuch as, in the one case, it is converted by nitrous acid into *elaïdic* acid, and in the other it is not thus changed. (*Note to the fourth edition.*)

As, besides oleic, stearic, and margaric acids, there are in certain oils other analogous fatty acids, such as the *palmitic*, for example, which united with glycerin forms *palmitin;* so, besides glycerin or oxide of glyceryl, there are other bases of fatty salts, as oxide of cetyl, oxide of propyl, &c. So far as these have particular interest for the pharmaceutist they will be considered under the several substances into the constitution of which they enter. To distinguish the oils having glycerin for their base, they are now denominated *glycerides.*

The fixed oils are liable to certain spontaneous changes, which have been investigated by MM. Pelouze and Boudet. It appears, from their researches, that the oils are accompanied, in the seeds which contain them, with principles which act as a ferment, and cause the oils to resolve themselves spontaneously into the several fatty acids which they afford on saponification, and into glycerin. This change takes place in the seeds as soon as the cells containing the oil are broken, so as to permit the contact of the fermenting principle existing in the grain. Sometimes the fermenting principle is to a certain extent separated from the seeds along with the oil. In such a case, the oil undergoes this resolution into the fatty acids and glycerin after expression. Such was ascertained to be the case with palm oil, in which, after long keeping, MM. Pelouze and Boudet detected the presence of glycerin, and of palmitic and oleic acids. They moreover proved that, under the continued influence of the ferment, the fatty acids themselves undergo changes, among which is the conversion of the oleic into sebacic acid; and it is probable that, with a still longer continuance of the same influence, the oil would be completely destroyed. (*Journ. de Pharm.*, Avril, 1856, p. 274.)

As this rancidity in fats renders them altogether useless for most practical purposes in pharmacy, and as it is not always readily discoverable by the senses in its earlier stages, it becomes desirable to possess a test by which it may be readily detected. Such a test is to be found, according to Mr. Thos. B. Groves, in iodide of potassium, which is rapidly decomposed by the new principles developed, and, by the orange-brown discoloration produced by the liberation of the iodine, indicates the existence of rancidity, and by the rapidity and degree of that discoloration approximatively the extent of the change. The alteration of colour is said by Mr. Groves to be plainly perceptible when only one-twentieth of rancid fat is present in any mixture of fats.

It is also extremely important to be able to protect fats against this change. The complete exclusion of air, light, and moisture; and, when in relation to air this may not be entirely practicable, the destruction by heat of the ferment-germs contained in the air, by which the decomposition is often originated, will go far to effect this object; but it would often be very inconvenient, if not impossible, to carry these measures into complete effect; and hence the discovery of substances which may have the effect of retarding, if not wholly preventing these fermenting processes, whether by the destruction of the ferment-germs or otherwise, is extremely desirable. It is now long since one or more substances having this preservative effect have been made known and practically used; and, since the principle upon which they are supposed to act has been discovered, the number has been much extended. Thus benzoin rubbed up with fats is well known to preserve them long against rancidity, and *benzoated lard*, made by mixing one part of benzoin with 44 parts of melted lard, is one of the preparations of the present British Pharmacopœia; and the buds of the poplar (*Populus nigra*) are perhaps still more effectual; as, according to M. Deschamps, lard impregnated with their virtues will keep good indefinitely. In the French Codex the poplar buds are employed for this purpose in the "*Pommade Populeum*," in which eight parts of the dried buds are used to 60 parts of the ointment, consisting of lard impregnated with the virtues of several narcotic substances; the fresh narcotic plants being boiled with lard until all their water is evaporated, and the buds afterwards digested in the strained liquid for 24 hours. Mr. Groves made experiments with many volatile oils and other analogous substances to test their preservative power; and, while many of them were found to have considerable effect, as cloves, Peruvian balsam,

sassafras, guaiacum, and creasote, yet the one which appeared to act most efficiently was the *oil of pimento;* and he proposes to add to the officinal *prepared lard* of the British Pharmacopœia, either oil of pimento or balsam of Peru, in the proportion of two drops to the ounce, in order to contribute to its preservation. (See *Am. Journ. of Pharm.*, Jan. 1865, pp. 54, 61.)

Animal fats are especially liable to become rancid when kept; and it is very desirable to obviate this effect; for, instead of having the mild demulcent properties which constitute their chief value, they become irritant, and unfit as vehicles for other substances to be applied to the skin. Prof. Hirzel says that animal fats may be kept in a good condition for a year by the following plan. Mix 14 pounds of the recently melted fat with 5 drachms of common salt and 15 grains of alum, in fine powder, heat till a scum is formed on the surface, separate the scum, and, when the clear liquid has cooled, wash it many times with water with malaxation, so as to remove all the salt, then evaporate the water at a heat insufficient to injure the fat. (*Am. Journ. of Pharm.*, July, 1868, p. 334.)

It is sometimes desirable to deprive the fixed oils of colour. The following process for this purpose is recommended by M. Brunner. The oil is first brought to the state of emulsion by strongly agitating it with water rendered mucilaginous by gum or starch; the emulsion is treated for each part of oil with two parts of wood-charcoal, previously well heated, and coarsely powdered, the finer particles being sifted out; the pasty mass is then completely dried at a heat not exceeding 212° F., and exhausted by cold ether in a percolator; finally, the ethereal solution, having been allowed to stand in order that any charcoal present in it may subside, is submitted to distillation so as to separate the ether, and the oil remains colourless in the retort. (*Journ. de Pharm.*, Sept. 1858, p. 214.)

M. Berlandt recommends the following method of bleaching fixed oils. Shake strongly for some minutes 900 parts of the oil, with 120 parts of water holding in solution 3 parts of permanganate of potassa, allow the mixture to stand for some hours in a warm place, and then filter. The oil becomes colourless. (*Journ. de Pharm. et de Chim.*, Oct 1867, p. 314.)

The ultimate constituents of the fixed oils are carbon, hydrogen, and oxygen; the hydrogen being in much larger proportion than is necessary to saturate the oxygen. Those which are least fusible contain most carbon and least oxygen; and, according to De Saussure, their solubility in alcohol is greater in proportion to their amount of oxygen. (*Berzelius.*) Some of them contain a very minute proportion of nitrogen.

2. OLEA VOLATILIA. *Volatile Oils.*

These are sometimes called *distilled oils*, from the mode in which they are usually procured; sometimes *essential oils*, from the circumstance that they possess, in a concentrated state, the properties of the plants from which they are derived. They exist in all odoriferous vegetables, sometimes pervading the plant, sometimes confined to a single part; in some instances contained in distinct cellules, and preserved after desiccation, in others formed upon the surface, as in many flowers, and exhaled as soon as formed. Occasionally two or more are found in different parts of the same plant. Thus, the orange tree produces one oil in its leaves, another in its flowers, and a third in the rind of its fruit. In a few instances, when existing in distinct cellules, they may be obtained by pressure, as from the rind of the lemon and orange; but they are generally procured by distillation with water. (See *Olea Destillata.*) Some volatile oils, as those of bitter almonds and mustard, are formed, during the process of distillation, out of substances of a different nature pre-existing in the plant.

The volatile oils are usually yellowish, but often brown, red, green, or blue, and occasionally colourless. There is reason, however, to believe that, in all instances, the colour depends on foreign matter dissolved in the oils. Septimus Piesse has succeeded, by the fractional distillation of certain volatile oils, in

separating a blue liquid, which, by repeated rectification, he has obtained quite pure. In this state, it has the sp. gr. 0·910, and a fixed boiling point of 576° F., and yields a dense blue vapour, having peculiar optical properties. He has named this principle *azulene*, and believes that upon it depends the blueness of volatile oils wherever existing. The yellowness of the oils he ascribes to the resin resulting from their oxidation, the green and brown colours to a mixture of azulene and resin in various proportions. The formula of azulene is $C_{16}H_{13}O$. (*Chem. News*, Nov. 21, 1863, p. 245.)

The volatile oils have a strong odour, resembling that of the plants from which they were procured, though generally less agreeable. Their taste is hot and pungent, and, when they are diluted, is often gratefully aromatic. The greater number are lighter than water; some are heavier; and their sp. gr. varies from 0·847 to 1·17. They partially rise in vapour at ordinary temperatures, diffusing their peculiar odour, and are completely volatilized by heat. Their boiling point is various, generally as high as 320° F., and sometimes higher; but most of them rise readily with the vapour of boiling water. When distilled alone, they almost always undergo partial decomposition. They differ also in their point of congelation. A few are solid at ordinary temperatures, several become so at 32° F., and may remain liquid considerably below that point. Heated in the open air, they take fire and burn with a bright flame attended with much smoke. Almost all those hitherto examined have the property of very decidedly deviating the plane of polarization of light, some in one direction, and some in the other; and advantage may sometimes be taken of this property to detect adulterations of one of these oils with another.

Exposed at ordinary temperatures, they absorb oxygen, assume a deeper colour, become thicker and less odorous, and are ultimately converted into resin.* This change takes place most rapidly under the influence of light. Before the alteration is complete, the remaining portion of oil may be recovered by distillation. Some of them form well characterized acids by combination with oxygen.†

The volatile oils are very slightly soluble in water. Agitated with this fluid they render it milky; but separate upon standing, leaving the water impregnated with their odour and taste. This impregnation is more complete when water is distilled with the oils, or from the plants containing them. Trituration with magnesia or its carbonate renders them much more soluble, probably in consequence of their minute division. The intervention of sugar also greatly increases their solubility, and affords a convenient method of preparing them for internal use. Most of them are very soluble in alcohol, and in a degree proportionate to its freedom from water. The oils which contain no oxygen are scarcely soluble in diluted alcohol; and, according to De Saussure, their solubility generally in this liquid is proportionate to the quantity of oxygen which they contain. They are readily dissolved by ether.

The volatile oils dissolve sulphur and phosphorus with the aid of heat, and deposit them on cooling. By long boiling with sulphur, they form brown, unc-

* Some interesting observations have been made by M. Auguste Houzeau, in reference to the chemical influence of the atmosphere, which go to prove that, in reference at least to the air at Rouen, in France, which was the site of these observations, this influence varies in degree with the season, being greatest in the advanced spring or early summer (May and June), diminishing sensibly in the summer and greatly in autumn, and increasing at the close of winter and the beginning of spring. If this be generally true, the change in oils, as well as in all other bodies oxidizable in the air, should be greatest at that period of the year when the atmospheric influence is greatest, namely, in May and June, and least when this is least, in the winter months. (*Journ. de Pharm. et de Chim.*, 4e sér., ii. pp. 212–218.)—*Note to the thirteenth edition.*

† *Recovery of volatile oils from their resinified condition.* A process for this purpose, employed by M. Curieux, is to treat the old resinified oil with a solution of borax and animal charcoal; these being first mixed to form a magma, the oil then added, and the mixture shaken for fifteen minutes. The borax unites with the resinous matter; and the magma, adhering to the sides of the vessel, leaves the oil clear and possessed of its original properties. (*Am. Journ. of Pharm.*, Sept. 1858, p. 398; from *Journ. de Chim. Méd.*)—*Note to the twelfth edition*

tuous, fetid substances, formerly called *balsams of sulphur*. They absorb chlorine, which converts them into resin, and then combines with the resin. Iodine produces a similar effect. They are decomposed by the strong mineral acids, and unite with several of those from the vegetable kingdom. When treated with a caustic alkali, they are converted into resin, which unites with the alkali to form a kind of soap. Several of the metallic oxides, and various salts which easily part with oxygen, convert them into resin. The volatile oils dissolve many of the proximate principles of plants and animals, such as the fixed oils and fats, resins, camphor, and several of the organic alkalies. Exposed to air and light, they acquire a decolorizing property, analogous to that of chlorine, which is ascribed by Faraday to their combination with the ozonized oxygen of the atmosphere. For some interesting observations on this property of the volatile oils, the reader is referred to papers by Dr. J. L. Plummer, of Richmond, Indiana, in the *American Journal of Pharmacy* (xxv. 398 and 508).*

The volatile, like the fixed oils, are mixtures of two or more principles, which differ in their point of volatilization or congelation, or in their composition. It is, however, impossible to separate them by distillation alone so as to obtain the several principles entirely pure. When, as often happens, the constituents congeal at different temperatures, they may be separated by compressing the frozen oil between folds of bibulous paper. The solid matter remains within the folds; and the fluid is absorbed by the paper, from which it may be separated by distillation with water. The name of *stearoptene* has been proposed for the former, that of *eleoptene* for the latter. The solid crystalline substances deposited by volatile oils upon standing are also called stearoptenes. Some of them are denominated *camphors*, from their resemblance to true camphor. Some are isomeric with the oils in which they are formed, others are oxides. Certain oils, under the influence of water, deposit crystalline hydrates of the respective oils.

In reference to their ultimate constituents, the volatile oils may be divided into three sets: 1. the *non-oxygenated*, consisting exclusively of carbon and hydrogen, as the oils of turpentine and copaiba; 2. the *oxygenated oils*, containing carbon, hydrogen, and oxygen, as oil of cinnamon and most of the aromatic oils; and 3. the *sulphuretted*, containing sulphur, as the oils of horseradish and mustard. In relation to the first division, or non-oxygenated oils, it is a remarkable fact, that, however differing in sensible properties, almost all of them contain carbon and hydrogen in the same proportion; their formulas being the same, or differing only in the whole number of equivalents; as C_5H_4, $C_{10}H_8$, and $C_{20}H_{16}$, of which the last two are simple multiples of the first.

The volatile oils are often sophisticated. Among the most common adulterations are fixed oils, resinous substances, and alcohol. The presence of the fixed oils may be known by the permanent greasy stain which they leave on paper, while that occasioned by a pure volatile oil disappears entirely when exposed to heat. They may also in general be detected by their comparative insolubility in alcohol. Both the fixed oils and resins are left behind when the adulterated oil is distilled with water. If alcohol is present, the oil becomes milky when agitated with water, and, after the separation of the liquids, the water occupies more space and the oil less than before. The following method of detecting alcohol was proposed by M. Béral. Put twelve drops of the suspected oil in a perfectly dry watch-glass, and add a piece of potassium about as large as the head of a pin. If the potassium remains for twelve or fifteen minutes in the midst of the liquid, there is either no alcohol present, or less than 4 per cent. If it disappears in five minutes, the oil contains more than 4 per cent. of alcohol; if in less than a minute, 25 per cent. or more. M. Borsarelli employs chloride of calcium for the same purpose. This he introduces in small pieces,

* See also the same journal (xxviii. 197) for some curious facts in relation to a repulsive influence exerted upon, and changes of colour produced in a mixture of chromate of potassa and sulphuric acid, by different volatile oils, at sensible and sometimes considerable distances from the mixture, effected probably through the vapour of the oils. (*Note to the eleventh edition.*)

well dried and perfectly free from powder, into a small cylindrical tube, closed at one end, and about two thirds filled with the oil to be examined, and heats the tube to 212°, occasionally shaking it. If there is a considerable proportion of alcohol, the chloride is entirely dissolved, forming a solution which sinks to the bottom of the tube; if only a very small quantity, the pieces lose their form, and collect at the bottom in a white adhering mass; if none at all, they remain unchanged. (*Journ. de Pharm.*, xxvi. 429.) J. J. Bernoulli proposes as a test dry acetate of potassa, which remains unaffected in a pure oil, but is dissolved if alcohol is present, and forms a distinct liquid. (See *Am. Journ. of Pharm.*, xxv. 82.) Sometimes volatile oils of little value are mixed with the more costly. The taste and smell afford in this case the best means of detecting the fraud. The specific gravity of the oils may also serve as a test of purity. When two oils, of which one is lighter and the other heavier than water, are mixed, they are separated by long agitation with this fluid, and will take a place corresponding to their respective specific gravities; but it sometimes happens that an unadulterated oil may thus be separated into two portions. The difference of apparent effect produced by iodine with the several oils has been proposed as a test; and bromine has been employed for the same purpose by Mr. John M. Maisch. Mr. Maisch uses both these tests preferably in the state of ethereal solution; which, as it is liable to spontaneous change by keeping, should be prepared when wanted for use.* According to Liebig, when iodine is made to act on a volatile oil, a portion of it combines with the hydrogen of the oil forming hydriodic acid, while another portion takes the place of the lost hydrogen. Oil of turpentine may be detected by remaining in part undissolved, when the suspected oil is treated with three or four times its volume of alcohol of the sp. gr. 0·84; or, according to M. Mero, by causing the suspected oil, when agitated with an equal measure of poppy oil, to remain transparent, instead of becoming milky, as it would do if pure. The latter test will not apply to the oil of rosemary. (*Journ. de Pharm.*, 3e sér., vii. 303.) G. S. Heppe suggests a very delicate test of oil of turpentine and most other non-oxygenated oils, when used to adulterate one of the oils containing oxygen. A piece of nitroprusside of copper, of the size of a pin's head, is put into a little of the suspected oil in a test-tube, and heated until the liquid begins to boil. The boiling must be continued only a few seconds. If the oil be pure and oxygenated, the nitroprusside of copper will become black, brown, or gray; if oil of turpentine or other non-oxygenated oil be present, the deposit will be green or bluish-green, and the supernatant liquid colourless or yellowish. (*Chem. Gaz.*, Ap. 15, 1857, p. 155.)†

The different relation of the volatile oils to polarized light may, to a certain extent, be made available for the detection of adulterations, especially where the action of the adulterating oil is in an opposite direction to that adulterated. Thus the oils of juniper, lavender, rosemary, rotate the plane of polarization to the left, while American oil of turpentine rotates to the right; and if this should be added to one of the other oils, it might in some degree neutralize their action, and thus offer one means for its detection. Unfortunately, the French oil of turpentine, from the juice of the Pinus maritima, acts strongly in the opposite direction. But the very strength of its left rotatory power may lead to its detection by the abnormal increase of this power which it might impart to the oils in question. An instrument called the *polariscope* is necessary in these investigations; and the reader is referred, for the description of such an instrument, with a table of the direction and degree of this rotating power in several of the oils most employed, to a paper, by Mr. H. Sugden Evans, in the *Pharmaceutical Journal and Transactions* (Oct. 1865, p. 220).

Volatile oils may be preserved without change in small well-stopped bottles, entirely filled with the oil, and secluded from the light. W.

* Mr. Maisch's paper on the application of these tests to the several volatile oils is contained in the *Proceedings of the American Pharm. Association*, A.D. 1859, p. 342.

† For an elaborate paper on the detection of adulterations in volatile oils, by Mr. John M. Maisch, see *Proceedings of the Am. Pharm. Association*, A. D. 1858, p. 344.

OLEUM AMYGDALÆ AMARÆ. *U.S.*

Oil of Bitter Almond.

The oil obtained by distilling with water the kernels of the fruit of Amygdalus communis, variety amara. *U. S.*

When bitter almonds are expressed, they yield a bland fixed oil; and the residuary cake, reduced to powder by grinding, and submitted to distillation with water, gives over a volatile oleaginous product, commonly called oil of bitter almonds. This does not pre-exist in the almond, but is produced by the reaction of water upon the amygdalin contained in it, through the intervention of another constituent denominated emulsin. (See *Amygdala Amara.*) It is obtained also by the distillation of the leaves of the cherry-laurel, and of various products of the genera Amygdalus, Cerasus, Prunus, and others. (See *note, page* 117.) Mr. Whipple obtained, upon an average, from the ground bitter almond cake, 1·35 per cent. of the oil. (*Pharm. Journ.*, x. 297.) Pettenkoffer has ascertained that the product is greater, if the cake be macerated in water for forty-eight hours before being submitted to distillation. (*Journ. de Pharm.*, Mai, 1862, p. 432.)

Oil of bitter almonds has a yellowish colour, a bitter, acrid, burning taste, and the odour of the kernels in a high degree. It is heavier than water, soluble in alcohol and ether, slightly soluble in water, and deposits, upon standing, a white crystalline substance consisting chiefly of benzoic acid. Besides a peculiar volatile oil, it contains also hydrocyanic acid, with a small proportion of benzoic acid, and of a concrete principle called *benzoïne.* It may be obtained pure by agitating it strongly with hydrate of lime and a solution of protochloride of iron, submitting the mixture to distillation, and drying the oil which comes over by digestion with chloride of calcium. Mr. George Whipple states that, if crude oil be redistilled into a solution of nitrate of silver, and again distilled from a fresh solution of the same salt, it is obtained entirely free from hydrocyanic acid, which reacts with the silver, and remains behind as cyanuret of silver. (See *Am. Journ. of Pharm.*, xxvi. 348.) Thus purified it is colourless, but still retains its peculiar odour, with a burning, aromatic taste; and is destitute of the poisonous properties of the oil in its original state, dependent on hydrocyanic acid. The odour of the oil of bitter almonds has been erroneously ascribed to that acid, which, on examination, will be found to smell differently and more feebly. Like most other volatile oils, this may produce deleterious effects if taken very largely. Hippuric acid is found in the urine of animals to which it has been given freely. The sp. gr. of the crude oil varies from 1·052 to 1·082, and is said to be greater when the oil is distilled from salt water than in the ordinary mode. That of the purified oil is 1·043, and its boiling point 356°. It probably consists of a compound radical called *benzyl* ($C_{14}H_5O_2$) and one eq. of hydrogen, and is therefore a *hydruret of benzyl.* This radical is capable of uniting with other bodies, and forming a series of compounds. The benzoic acid which the oil of bitter almonds deposits on standing does not pre-exist in it, but results from the absorption of oxygen. The concrete substance above referred to by the name of *benzoïne* is isomeric with the oil, crystallizable in colourless shining prisms, without smell or taste, fusible at 248°, and volatilizable unchanged at a higher temperature. It is formed abundantly in the original impure oil by the reaction of alkalies; but cannot be produced in it when deprived of hydrocyanic acid.* Schönbein has satisfied himself that oil of bitter almonds

* *Nitrobenzole, Nitrobenzine, or Artificial Oil of Bitter Almonds.* This substance was discovered by Mitscherlich, who obtained it by the reaction of nitric acid on *benzole*, a carbohydrogen originally procured by distilling benzoic acid with lime. (See *Part* III.) It is characterized by having an odour closely resembling that of the oil of bitter almonds, for which it has recently been substituted to a considerable extent in perfumery, in consequence of the discovery of benzole among the products of the distillation of coal tar, and the facility thus offered for preparing nitrobenzole cheaply. In its preparation a

has, like electricity and phosphorus, an ozonizing effect on oxygen. (*Chem Central Blatt*, Dec. 15, 1858, p. 905.)

Zeller mentions, as characteristics of the officinal oil by which its genuineness and purity may be known, its peculiar odour and high specific gravity; its ready solubility in sulphuric acid, with the production of a reddish-brown colour, but without visible decomposition; the slow action of nitric acid; the slow and partial solution of iodine without further reaction; the want of action of chromate of potassa upon it; and the production of crystals when it is dissolved in an alcoholic solution of potassa. (See *Pharm. Journ.*, ix. 575.) Mr. Redwood states that a very small proportion of alcohol may be detected in the oil, by the effervescence, with disengagement of nitrous vapours, which ensues when the oil, thus contaminated, is mixed with an equal volume of nitric acid, of the sp. gr. 1·5. With pure oil no other effect is obvious than a slight change of colour. (*Ibid.*, xi. 486.) If sulphuric acid produces with the oil a bright-red, instead of a brownish-red colour, it indicates that the oil has probably been distilled with salt water, in which case it is apt, according to Mr. Ferris, to deposit a blood-red matter, occasionally complained of by druggists. (*Ibid.*, p. 565.)

Mr. Wm. A. Tilden has found that the introduction of a little fused chloride of calcium into purified oil of bitter almonds contributes to its preservation,

large glass worm is used, bifurcated at its upper end, so as to form two funnel-shaped tubes. Into one of these concentrated nitric acid is poured, and into the other benzole, and the two, meeting at the point of junction of the tubes, form the compound in question, which is cooled as it passes through the worm, and is afterwards fitted for use by washing it with water, or dilute solution of carbonate of soda. Much of it is consumed, in London, for scenting soap, in confectionery, and for culinary purposes, to which it is even better adapted than the proper oil of bitter almonds, because free from hydrocyanic acid. (*Pharm. Journ.*, xi. 421.) Van den Corput has found nitrobenzine a perfect cure for the itch. One or two frictions well made are sufficient to kill both the insect and its eggs. He mixes the nitrobenzine with twice its weight of glycerin, and applies it by means of a woollen rag impregnated with the mixture, having previously cleansed the body by vigorous friction with soft soap, followed by a bath. (*Ann. de Thérap.*, 1865, p. 156.)

In the twelfth edition of the *U. S. Dispensatory*, it is said that nitrobenzine is not destitute of activity, and should not, therefore, be incautiously used. Abundant evidence has since been obtained, proving it to possess highly poisonous properties. Not only has it been proved to be capable of destroying life in the lower animals, but it has also, in several instances, proved fatal in man; acting as a powerful narcotic poison, whether taken into the stomach, or inhaled in the state of vapour. In one case death took place from the swallowing, as was supposed, of about 15 drops of the poison; in a second, from an indefinite quantity taken into the stomach; in a third, from the breathing for several hours of the vapour of some nitrobenzole which had been spilled upon the clothes. In all the cases there was loss of consciousness, beginning with sensations as of intoxication, and increasing to profound coma, in which the patient died without vomiting, convulsion, or struggle of any kind; the whole duration of the case being about nine hours, four before the coming on of coma, and five from that point till death. After death there were appearances of general venous congestion, both internally and externally; the brain and its membranes were congested, with much bloody serosity in the ventricles; the cavities of the heart were full of blood; and nitrobenzole as well as anilin, into which it appeared to have been converted, were detected in the brain and stomach. Several instances are recorded in which serious consequences have followed the inhalation of the vapour escaping from soap scented with nitrobenzole. (Dr. Alfred S. Taylor, *Guy's Hospital Reports*, 3d ser., x. 192, A. D. 1864.)—*Note to the thirteenth edition.*

Mr. J. M. Maisch has known nitrobenzole to be used for the adulteration of the oil of bitter almonds, and proposes the following mode of detecting it. Dissolve half a drachm of the suspected oil in two or three drachms of alcohol, add fifteen grains of pure fused caustic potassa, heat for a few minutes so as to dissolve the potassa and reduce the liquid to one-third, and then set aside to cool. If the oil be pure it will remain liquid, while, if nitrobenzole be present, there will, after cooling, be a crystalline deposit proportionate to the amount of adulteration. (*Am. Journ. of Pharm.*, Nov. 1857, p. 544.) R. Wagner proposes the sp. gr. of the two oils as a test; that of the oil of bitter almonds being from 1·04 to 1·044, while that of nitrobenzole is 1·18 to 1·201; and a mixture will have a higher sp. gr. than the pure oil. This would lead to the suspicion of the presence of nitrobenzole, which may then be separated by agitation with bisulphite of soda. The almond oil will dissolve, while the nitrobenzole will float on the surface. (*Journ. de Pharm. et de Chim.*, Mai, 1868, p. 399.)—*Note to the tenth, twelfth, and thirteenth editions*

probably by the absorption of the last traces of water contained in it. Of two specimens of the oil, which had been set aside for two years, one without addition, the other containing a fragment of the fused chloride, the former was found filled with crystals of benzoic acid, the latter was perfectly free from crystalline deposit and quite fluid. (*Pharm. Journ. and Trans.*, 2d ser., viii. 325, Dec. 1866.)

Medical Properties and Uses. The unpurified volatile oil of bitter almonds, which is the product directed by the Pharmacopœia, operates upon the system in a manner closely analogous to that of hydrocyanic acid. A single drop is sufficient to destroy a bird, and four drops have caused the death of a dog of middle size. The case of a man is recorded, who died in ten minutes after taking two drachms of the oil. It might probably be substituted with advantage for medicinal hydrocyanic acid; as the acid contained in the oil is much less liable to decomposition, remaining for several years unaltered, if the oil is preserved in well-stopped bottles. According to Schrader, 100 parts of the oil contain sufficient acid for the production of 22·5 parts of Prussian blue; but the proportion is not constant, varying, according to Mr. Groves, from 8 to 12·5 per cent. From one-fourth of a drop to a drop may be given for a dose, to be cautiously increased till some effect upon the system is observed. It may be administered in emulsion with gum arabic, loaf sugar, and water. It has been employed externally, dissolved in water in the proportion of one drop to a fluidounce, in prurigo senilis and other cases of troublesome itching. To facilitate the solution in water, the oil may be previously dissolved in spirit. Oil of bitter almonds is said to conceal the taste of cod-liver oil and of castor oil.

OLEUM AMYGDALÆ DULCIS. *U. S.*

Oil of Sweet Almond.

The fixed oil obtained from the kernels of the fruit of Amygdalus communis, variety dulcis. *U. S.*

Off. Syn. OLEUM AMYGDALÆ. *Almond Oil.* The oil expressed from bitter and sweet almonds. *Br.*

Huile d'amandes, *Fr.;* Mandelöl, *Germ.;* Olio di mandorle, *Ital.;* Aceyte de almendras, *Span.*

See AMYGDALA.

This oil is obtained equally pure from sweet and bitter almonds. In its preparation, the almonds, having been deprived of a reddish-brown powder adhering to their surface, by being rubbed together in a piece of coarse linen, are ground in a mill resembling a coffee-mill, or bruised in a stone mortar, and then pressed in canvas sacks between plates of iron slightly heated. The oil, which is at first turbid, is clarified by rest and filtration. Sometimes the almonds are steeped in very hot water, deprived of their cuticle, and dried in a stove, previously to expression. The oil is thus obtained free from colour, but in no other respect better, while it is more apt to become rancid on keeping. Bitter almonds, treated in this way, impart a smell of hydrocyanic acid to the oil. M. Boullay obtained 54 per cent. of oil from sweet almonds, Vogel 28 per cent. from bitter almonds. Munch gives 55·4 per cent. as the yield of the former, and 52 per cent. as that of the latter. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 400.) Though sometimes expressed in this country from imported almonds, the oil is generally brought from Europe.

Oil of almonds is clear and colourless, or slightly tinged of a greenish-yellow, is nearly inodorous, and has a bland sweetish taste. It remains liquid at temperatures considerably below the freezing point of water. Its sp. gr. is from 0·917 to 0·92. From the statement of Braconnot, it appears to contain 76 per cent. of olein and 24 of margarin.

Oil of almonds is said to be sometimes adulterated with poppy oil, or other drying oils of less value. This sophistication may be detected, as suggested by

M. Wimmec, by taking advantage of the property of being converted into solid elaidic acid by the action of nitric acid, belonging to the olein of the non-drying but not to that of the drying oils. By treating iron filings with nitric acid in a flask, nitrous acid is produced, which is to be conducted into water upon which the suspected oil is placed If the almond oil contain even but a small quantity of poppy oil, or other drying oil, this will remain in the form of drops on the surface, while the genuine oil will be converted entirely into crystallized elaidin. (*Journ. de Pharm.*, Dec. 1862, p. 500.)

Colza oil, another not uncommon adulteration, may be detected, according to M. Schneider, by the action of nitrate of silver. Dissolve the oil in twice its volume of ether, add about 30 drops of a concentrated alcoholic solution of the nitrate, shake the mixture, and allow it to stand in the dark. If there be much colza oil, the lower part of the liquid will become first brown and then black; if but little, the brown colour will not appear for about 12 hours; but always the discoloration will be obvious on the evaporation of the ether. (*Pharm. Journ.*, March, 1862, p. 484.)

It is said that, in the south of France, the sweet almond oil is sometimes adulterated with a cheaper oil, called the *oil of apricots*. According to M. J. Nicklés, this adulteration may be detected by means of powdered hydrate of lime, which with the oil of apricots forms an emulsion that slowly assumes an unctuous consistence, while it has no such action on the almond oil, merely rendering it opaque for a time, and then gradually separating and leaving the oil clear. A mixture of the two oils emulsionizes with the lime, and on standing deposits the unctuous matter referred to. (See *Am. Journ. of Pharm.*, July, 1866, p. 289.)

Oil of almonds may be used for the same purposes with olive oil; and, when suspended in water by means of mucilage or the yelk of eggs and loaf sugar, forms a pleasant emulsion, useful in pulmonary affections attended with cough. From a fluidrachm to a fluidounce may be given at a dose.

OLEUM ANTHEMIDIS. *Br.*

Oil of Chamomile.

The oil distilled in Britain from chamomile flowers. *Br.*

For an account of the plant yielding this oil, see ANTHEMIS, *page* 127.

This oil has been introduced into the Materia Medica list of the British Pharmacopœia, under the name of *English Oil of Chamomile*, and with the direction that it shall be distilled in England. It is seldom prepared or used in this country. Baumé obtained thirteen drachms of the oil from eighty-two pounds of the flowers; according to Mr. Brande, the average product of 100 pounds is two pounds twelve ounces. It has the peculiar smell of chamomile, with a pungent somewhat aromatic taste. When recently distilled it is of a pale sky-blue or greenish-blue colour, which changes to yellow or brownish on exposure. The sp. gr. of the English oil is said to be 0·9083. According to M. Gerhardt, oil of chamomile is a mixture of a carbohydrogen ($C_{20}H_{16}$) with an oxygenated oil ($C_{10}H_6O_2$). (*Chem. Gaz.*, vi. 483.) It has sometimes been employed in spasm of the stomach, and as an adjunct to purgative medicines. Its chief use, however, appears to be as an ingredient of the extract of chamomile of the British Pharmacopœia, to which it is added in order to supply the place of the oil driven off by the heat used in its preparation. This oil must not be confounded with the product of *Matricaria Chamomilla*, employed on the continent of Europe under the name of oil of chamomile. (See *Matricaria.*) The dose is from five to fifteen drops.

OLEUM BERGAMII. *U.S.*

Oil of Bergamot.

The volatile oil obtained from the rind of the fruit of Citrus Limetta (*De Candolle*). *U. S.*

Huile de bergamotte, *Fr.;* Bergamottöl, *Germ.;* Olio di bergamotta, *Ital.*

CITRUS. See AURANTII CORTEX.

Citrus Limetta. De Cand. *Prodrom.* i. 539. The bergamot tree has been generally ranked among the lemons; but is now considered as a variety of the Citrus Limetta of Risso, and is so placed by De Candolle. It has oblong-ovate dentate, acute, or obtuse leaves, somewhat paler on the under than the upper surface, and with footstalks more or less winged or margined. The flowers are white, and usually small; the fruit pyriform or roundish, terminated by an obtuse point, with concave receptacles of oil in the rind.

The pulp of the fruit is sourish, somewhat aromatic, and not disagreeable The rind is shining, and of a pale-yellow colour, and abounds in a very grateful volatile oil. This may be obtained by expression or distillation. In the former case, it preserves the agreeable flavour of the rind, but is somewhat turbid; in the latter, it is limpid but less sweet. The mode of procuring it by expression is exactly that used for oil of lemons. (See *Oleum Limonis.*) It is brought from Italy, the south of France, and Portugal.

The oil of bergamot, often called *essence of bergamot*, has a sweet, very agreeable odour, a bitter aromatic pungent taste, and a pale greenish-yellow colour. Its sp. gr. varies from 0·870 to 0·888 (*Lewis, Zeller*); and its composition is essentially the same as that of oil of lemons. It is distinguished from the lemon and orange oils by readily dissolving in *liquor potassæ*, and forming with it a clear solution. (*Zeller.*) Though possessed of the excitant properties of the volatile oils in general, it is employed chiefly, if not exclusively, as a perfume. W.

OLEUM BUBULUM. *U.S.*

Neats-foot Oil.

The oil prepared from the bones of Bos domesticus. *U. S.*

Huile de pied de bœuf, *Fr.;* Ochsenfussefett, *Germ.*

Neats-foot oil is obtained by boiling in water for a long time the feet of the ox, previously deprived of their hoofs. The fat and oil which rise to the surface are removed, and introduced into a fresh portion of water heated nearly to the boiling point. The impurities having subsided, the oil is drawn off, and, if required to be very pure, is again introduced into water, which is kept for twenty-four hours sufficiently warm to enable the fat which is mixed with the oil to separate from it. The liquid being then allowed to cool, the fat concretes, and the oil is removed and strained, or filtered through layers of small fragments of charcoal free from powder.

The oil is yellowish, and, when properly prepared, inodorous and of a bland taste. It thickens or congeals with great difficulty, and is, therefore, very useful for greasing machinery in order to prevent friction.

It was introduced into the officinal catalogue of the U. S. Pharmacopœia as an ingredient of the ointment of nitrate of mercury. It has recently been used as a substitute for cod-liver oil in scrofulous diseases, and, according to Dr. C. R. Hall, of England, with happy effects, especially in cases in which the latter does not agree with the stomach. It is apt to be laxative, and in certain cases proves useful in this way. It is given in the same dose as cod-liver oil. (See *Am. Journ. of Med. Sci.*, N. S., xxiv. 498.)

Off. Prep. Unguentum Hydrargyri Nitratis, *U. S.* W.

OLEUM CAJUPUTI. *U.S., Br.*

Oil of Cajeput.

The volatile oil obtained from the leaves of Melaleuca Cajuputi. *U.S.* The oil distilled from the leaves of Melaleuca minor. *Br.*

Huile de cajéput, *Fr.;* Cajeputöl, *Germ.;* Olio di cajeput, *Ital.;* Kayuputich, *Malay.*

MELALEUCA. *Sex. Syst.* Polyadelphia Icosandria. — *Nat. Ord.* Myrtaceæ. *Gen. Ch. Calyx* five-parted, semi-superior. *Corolla* five-petaled. *Stamens* about forty-five, very long, conjoined in five bodies. *Style* single. *Capsule* three-celled. *Seeds* numerous. *Roxburgh.*

It was long supposed that the oil of cajeput was derived from *Melaleuca leucadendron;* but from specimens of the plant affording it, sent from the Moluccas, and cultivated in the botanical garden of Calcutta, it appears to be a distinct species, which has received the name of *M. Cajuputi.* It corresponds with the *arbor alba minor* of Rumphius, and is a smaller plant than *M. leucadendron.* It is possible, however, that the oil may be obtained from different species of Melaleuca; as M. Stickel, of Jena, succeeded in procuring from the leaves of *M. hypericifolia,* cultivated in the botanical garden of that place, a specimen of oil not distinguishable from the cajeput oil of commerce, except by a paler green colour. (*Annal. der Pharm.*, xix. 224.) Two other species of Melaleuca, *M. viridifolia* and *M. latifolia,* large trees growing abundantly in the island of New Caledonia, are said to yield a volatile oil very analogous to the oil of cajeput. The leaves of different species of Melaleuca have been used advantageously, in the form of bath, in chronic rheumatism. (*Annuaire de Thérap.*, A. D. 1861, p. 67.)

Melaleuca Cajuputi. Rumphius, *Herbar. Amboinense,* tom. ii. tab. 17; Roxburgh, *Trans. Lond. Med. Bot. Soc.*, A. D. 1829; *Journ. of the Phil. Col. of Pharm.*, vol. i. p. 193. — *Melaleuca minor.* De Candolle. This is a small tree, with an erect but crooked stem, and scattered branches, the slender twigs of which droop like those of the weeping willow. The bark is of a whitish-ash colour, very thick, soft, spongy, and lamellated, throwing off its exterior layer from time to time in flakes. The leaves have short footstalks; are alternate, lanceolate, when young sericeous, when full grown smooth, deep-green, three and five-nerved, slightly falcate, entire, from three to five inches long, from one-half to three-quarters of an inch broad; and when bruised exhale a strong aromatic odour. The flowers are small, white, inodorous, sessile, and disposed in terminal and axillary downy spikes, with solitary, lanceolate, three-flowered bractes. The filaments are three or four times longer than the petals, and both are inserted in the rim of the calyx.

This species of Melaleuca is a native of the Moluccas, and other neighbouring islands. The oil is obtained from the leaves by distillation. It is prepared chiefly in Amboyna and Bouro, and is exported from the East Indies in glass bottles. The small proportion yielded by the leaves, and the extensive use made of it in India, render it costly.

Properties. Cajeput oil is very fluid, transparent, of a fine green colour, a lively and penetrating odour analogous to that of camphor and cardamom, and a warm pungent taste. It is very volatile and inflammable, burning without any residue. The sp. gr. varies from 0·914 to 0·9274. Its composition, according to Blanchet and Sell, is represented by the formula $C_{20}H_{16}+2HO$; and its boiling point is 347° F. Schmidt proposes the name of *cajeputene* for the carbohydrogen $C_{20}H_{16}$, of which it is a bihydrate. (*Trans. Royal Soc. Edin.*, xii. 360.) The oil is wholly soluble in alcohol. When it is distilled, a light colourless liquid first comes over, and afterwards a green and denser one. The green colour has been ascribed to a salt of copper, derived from the vessels in which the distillation is performed; and Guibourt obtained two grains and a half of oxide of copper from a pound of the commercial oil. But neither Brande nor Gœrtner could detect copper in specimens examined by them; and M. Lesson, who witnessed

the process for preparing the oil at Bouro, attributes its colour to chlorophyll, or some analogous principle, and states that it is rendered colourless by rectification. Guibourt, moreover, obtained a green oil by distilling the leaves of a Melaleuca cultivated at Paris. A fair inference is that the oil of cajeput is naturally green; but that, as found in commerce, it sometimes contains copper, either accidentally present, or added with a view of imitating or maintaining the fine colour of the oil. The proportion of copper, however, is not so great as to forbid the internal use of the oil; and the metal may be separated by distillation with water, or agitation with a solution of ferrocyanide of potassium.

The high price of cajeput oil has led to its occasional adulteration. Oil of rosemary, or that of turpentine, impregnated with camphor and coloured with the resin of milfoil, is said to be employed for the purpose. The best test, according to Zeller, is iodine, which, after a moderately energetic reaction, with little increase of temperature, and but a slight development of orange vapours, occasions immediate inspissation into a loose coagulum, which soon becomes a dry, greenish-brown, brittle mass.

Medical Properties and Uses. This oil is highly stimulant, producing when swallowed a sense of heat, with an increased fulness and frequency of pulse, and exciting in some instances profuse perspiration. It is much esteemed by the Malays and other people of the East, who consider it a panacea. They are said to employ it with great success in epilepsy and palsy. (*Ainslie.*) The complaints to which it is best adapted are probably chronic rheumatism, and spasmodic affections of the stomach and bowels, unconnected with inflammation. It has been extolled as a remedy in spasmodic cholera, and has been used also as a diffusible stimulant in low fevers. Of late it is said to have been used in some cases of cholera in the collapsed state with altogether unhoped-for success; being administered, in such cases, in the dose of from fifteen grains to a drachm in a single potion. (*Ann. de Thérap.*, 1867, p. 71; from the *Presse Médicale Belge.*) Diluted with an equal proportion of olive oil, it is applied externally to relieve gouty and rheumatic pains. Like most other highly stimulating essential oils, it relieves toothache, if introduced into the hollow of the carious tooth. M. Delvaux, who has made extensive use of this oil, has found it beneficial, internally given, in dyspepsia with flatulence, in the early stages and milder forms of cholera, in verminose affections in children, in chronic laryngitis and bronchitis, in chronic catarrh of the bladder, in chronic rheumatism of the joints with little or no swelling, and in painful chronic rheumatism of the muscles and fibro-muscular tissues, whether external or internal. Externally applied, M. Delvaux has derived great benefit from it in various cutaneous diseases, as pityriasis, psoriasis, and especially in that extremely obstinate affection of the face, acnea rosacea, which he has often succeeded in curing by the simple application of this oil, three times a day. (*Annuaire de Thérap.*, A.D. 1862, p. 38.) The dose is from one to five drops, given in emulsion, in the form of pill, or upon a lump of sugar.

OLEUM CAMPHORÆ. *U. S.*

Oil of Camphor.

The volatile oil obtained from Camphora officinarum. *U. S.*

As there are two camphors known in commerce, those, namely, of Camphora officinarum and of Dryobalanops Camphora, so there are two oils of camphor derived from those plants respectively. It is that of the Camphora officinarum which is recognised in our Pharmacopœia, being the one which most commonly reaches this country, and is almost exclusively found in the shops. As the Camphora officinarum has been already described under the head of Camphora, it is unnecessary to say anything more of it here. (See *Camphora*, page 201.) In the same place an account has been given of the mode of procuring the oil, as practised in the island of Formosa.

The commercial oil of camphor, as found in our markets, is a fluid of a light reddish-brown colour with a yellowish tint, having a strong odour precisely like that of camphor, a bitterish camphorous taste, and the specific gravity, according to Prof. Procter, of 0·940. As described by M. Lallemand, the oil of the Camphora officinarum is very fluid, scarcely coloured, and of a strong smell of camphor. It acts strongly on polarized light, and is dextrogyrate. Martius and Ricker give as its formula $C_{20}H_{16}O$. It begins to boil at 356° F., but the temperature gradually rises to 401°, when it remains stationary. The part which first comes over is the proper volatile oil; that which rises at the higher temperature condenses after distillation, and is true camphor. The former, when duly rectified, distils at 356°, and appears to be a carbohydrogen isomeric with pure oil of turpentine, forming a crystallizable compound with muriatic acid. (*Journ. de Pharm.*, Avril, 1860, p. 289.) Commercial oil of camphor is therefore a fluid carbohydrogen, holding camphor in solution.

The Dryobalanops oil of camphor is a different product, resembling the genuine oil in odour, yet having also something peculiar in addition, which enables it to be readily distinguished when the two are examined together. An account of this oil is given at *page* 204, in a note treating of the Dryobalanops Camphora and its products. A volatile oil, received by M. Biot from Dr. Junghun, who is said to have collected it from the Dryobalanops Camphora in the island of Sumatra, was sent to M. Lallemand, who describes it as somewhat viscid, of a strong balsamic odour and reddish colour, and as separable by distillation into a volatile liquid and a non-volatile matter, which concretes on cooling into a resinous brittle mass, resembling colophony. The volatile liquid consists of two distinct oils, isomeric with each other and with pure oil of turpentine, but differing in their boiling point, and in various other respects. The original oil yielded nothing similar to camphor. It is obviously a very different product from that which has been generally ascribed to the Dryobalanops, and much more closely resembles the turpentines than the camphorous oils. If it really was obtained from the Dryobalanops Camphora, this must be a very different tree from what it has been described to be; and the probability is, that there has been some mistake as to the origin of the oil described by M. Lallemand.

The oil of camphor has properties similar to those of camphor but more stimulant, and is especially applicable to affections of the stomach and bowels, in which an anodyne and stimulant impression is indicated, as flatulent colic and spasmodic cholera. It may also be used externally, as a rubefacient and anodyne liniment, diluted with soap liniment, or olive oil, in local rheumatism and neuralgic pains, bruises, sprains, &c. The dose is two or three drops. W

OLEUM CINNAMOMI. *U. S., Br.*

Oil of Cinnamon.

The volatile oil obtained from the bark of Cinnamomum Zeylanicum. *U. S.* The oil distilled from Cinnamon Bark. *Br.*

Huile de cannelle, *Fr.*; Zimmtöl, *Germ.*; Olio di cannella, *Ital.*; Aceyte de canéla, *Span.* See CINNAMOMUM.

There are two oils of cinnamon in commerce; one procured from the Ceylon cinnamon, which, as having the finest flavour, is the only one recognised by the U. S. and Br. Pharmacopœias; the other from the Chinese cinnamon, and often distinguished by the name of *oil of cassia*, which it held in the late Edinburgh Pharmacopœia. There is, however, no essential difference in the two oils; and that of the Chinese cinnamon, as much the cheaper and more abundant of the two, will probably continue to be generally employed, notwithstanding the official preference for the Ceylon product.

Oil of cinnamon of Ceylon is prepared in that island from inferior kinds of cinnamon, of insufficient value to pay the export duty. The following account of the method of extraction is given by Marshall. The bark, having been coarsely powdered, is macerated for two days in sea-water, and then submitted to distil-

lation. A light and a heavy oil come over with the water, the former of which separates in a few hours, and swims upon the surface, the latter falls to the bottom of the receiver, and continues to be deposited for ten or twelve days. In future distillations, the saturated cinnamon water is employed with sea-water to macerate the cinnamon. Eighty pounds of the freshly prepared bark yield about 2·5 ounces of the lighter oil, and 5·5 of the heavier. From the same quantity kept for several years in store, about half an ounce less of each oil is obtained. The two kinds are probably united in the oil of commerce.

Recently prepared oil of cinnamon is of a light-yellow colour, becoming deeper by age, and ultimately red. Pereira states that the London druggists redistil the red oil, and thus obtain two pale-yellow oils, one lighter and the other heavier than water, with a loss of about 10 per cent. in the process. The oil has the flavour of cinnamon, and when undiluted is excessively hot and pungent. It is said sometimes to have a peppery taste, ascribable to an admixture of the leaves with the bark in the preparation of the oil.

Chinese oil of cinnamon (*oil of cassia*) is imported from Canton and Singapore. Like the former it is pale-yellow, becoming red with age. Its flavour is similar to that of the Ceylon oil, though inferior; and it commands a much less price. Zeller states that it is heavier, less liquid, and sooner rendered turbid by cold, and that in the Ceylon oil iodine dissolves rapidly, with a considerable increase of heat, and the production of a tough residue, like extract, while in oil of cassia the reaction is slow, quiet, and with little heat, and the residue is soft or liquid. The following remarks apply to both.

Oil of cinnamon has the sp. gr. of about 1·035. Alcohol completely dissolves it; and, as it does not rise in any considerable quantity at the boiling temperature of that liquid, it may be obtained by forming a tincture of cinnamon and distilling off the menstruum. When exposed to the air, it absorbs oxygen, and is slowly converted into a peculiar acid denominated *cinnamic* acid, two distinct resins, and water. *Cinnamic acid* is colourless, crystalline, sourish, volatilizable, slightly soluble in water, readily dissolved by alcohol, and convertible by nitric acid with heat into benzoic acid. It is sometimes seen in crystals in bottles of the oil which have been long kept. Like benzoic acid, it is said when swallowed to cause the elimination of hippuric acid by urine. (*Journ. de Pharm.*, 3e sér., iii. 64.) It may be obtained by distilling the balsam of Tolu. Of the two resins, one is soluble both in hot and cold alcohol; the other readily in the former, but sparingly in the latter. Oil of cinnamon is almost wholly converted by nitric acid, slowly added, into a crystalline mass, thought to be a compound of the oil and acid. From the researches of Dumas and Peligot, it appears that there exists in the oil a compound radical, named *cinnamyl* ($C_{18}H_7O_2$), which with one eq. of hydrogen forms pure oil of cinnamon, or hydruret of *cinnamyl*, and with one of oxygen anhydrous cinnamic acid. Crystallized cinnamic acid contains, in addition, one eq. of water. All the constituents of the ordinary oils of cinnamon are supposed to be derived from the pure oil or hydruret of cinnamyl by the absorption of oxygen. The oil has been produced artificially by Strecker from styrone, a derivative from styrax. (See *Styrax.*)

Oil of cinnamon is said to be frequently adulterated with oil of cloves, which, according to Ulex, cannot be detected by the smell or taste. Thus sophisticated, it is stated, on the same authority, to evolve a very acrid vapour when a drop is heated on a watch-glass, to swell up and evolve red vapours if treated with fuming nitric acid, to remain liquid with concentrated caustic potassa, and to assume an indigo-blue colour when protochloride of iron is added to its alcoholic solution; none of which events happens when the oil is pure. (*Archiv. der Pharm.*, Jan. 7, 1853.) It is said also to be frequently adulterated with alcohol and fixed oil, the mode of detecting which is given in *page* 586.

Medical Properties and Uses. This oil has the cordial and carminative properties of cinnamon, without its astringency; and is much employed as an adjuvant to other medicines, the taste of which it corrects or conceals, while it conciliates the stomach. As a powerful local stimulant, it is sometimes prescribed

in gastrodynia, flatulent colic, and languor from gastric debility. The dose is one or two drops, and may be administered in the form of emulsion. Mitscherlich found six drachms to kill a moderate-sized dog in five hours, and two drachms in forty hours. Inflammation and corrosion of the gastro-intestinal mucous membrane were observed after death.

OLEUM LIMONIS. *U. S., Br.*

Oil of Lemon.

The volatile oil obtained from the rind of the fruit of Citrus Limonum. *U. S.* The oil expressed or distilled from fresh lemon peel. *Br.*

Huile de citron, *Fr.;* Citronenöl, *Germ.;* Olio di limone, *Ital.;* Aceyte de limon, *Span.* See LIMON.

The exterior rind of the lemon abounds in a volatile oil, which, being contained in distinct cellules, may be separated by simple expression. The rind is first grated from the fruit, and then submitted to pressure in a bag of fine cloth. The oil thus obtained is allowed to stand till it becomes clear, when it is decanted, and kept in stopped bottles. By a similar process, the oil called by the French *huile de cedrat* is procured from the citron. (See *Oleum Bergamii* and *Limon.*) These oils may also be obtained by distillation; but thus procured, though clearer, and, in consequence of the absence of mucilage, less liable to change on keeping, they have less of the peculiar flavour of the fruit; and the mode by expression is generally preferred. Prof Procter states that he learned, when in Naples, that a third method of separating the oil, in Calabria and Sicily, was to put the grated rind into hot water, and skim off the oil as it rises to the surface. (*Am. Journ. of Pharm.*, Jan. 1868, p. 27.) The oils are brought originally from Italy, Portugal, or the south of France.

Properties. Oil of lemons is a very volatile liquid, having the odour of the fruit, and a warm, pungent, aromatic taste. As commonly procured it is yellow, and has the sp. gr. 0·8517; but by distillation it is rendered colourless, and, if three-fifths only are distilled, its sp. gr. is reduced to 0·847, at 71° F. It is soluble in all proportions in anhydrous alcohol. In its ordinary state, it contains oxygen, but when purified by distillation *in vacuo*, at a low temperature, it consists exclusively of carbon and hydrogen, in the same proportion as in pure oil of turpentine, or camphene; its formula being $C_{20}H_{16}$. In this state it is capable of absorbing almost half its weight of muriatic acid gas, by which it is converted into a crystalline substance, and a yellow oily fuming liquid. The crystalline substance is analogous to artificial camphor, produced by the action of muriatic acid upon oil of turpentine, and is a compound of the oil and acid. The oil of lemons is said to consist of two isomeric oils.

It is often adulterated by the fixed oils and by alcohol. But in this country the most frequent sophistication is with oil of turpentine, which is difficult of detection from its similar composition and specific gravity. Perhaps the best test of the presence of this oil is the terebinthinate smell, produced when the adulterated oil is evaporated from heated paper. Oil of lemons, procured by expression, is apt to let fall a deposit, and to undergo chemical change. Mr. J. S. Cobb has found no method so effectual to obviate this result, and at the same time to retain unimpaired the flavour of the oil, as to shake it with a little boiling water, and allow the mixture to stand. A mucilaginous matter separates, and floats on the surface of the water, from which the purified oil may be decanted. (*Annals of Pharm.*, ii. 86.)

Medical Properties and Uses. Oil of lemons has the stimulant properties of the aromatics; but is chiefly used to impart flavour to other medicines. It has been commended as an application to the eye in certain cases of ophthalmia.

OLEUM LINI. *U.S., Br.*

Flaxseed Oil.

The oil obtained from the seed of Linum usitatissimum. *U. S.* The oil expressed without heat from linseed. *Br.*

Linseed oil; Huile de lin, *Fr.;* Leinöl, *Germ.;* Olio di lino, *Ital.;* Aceyte de linaza, *Span.* See LINUM.

This oil is obtained by expression from the seeds of *Linum usitatissimum*, or common flax, which, according to M. Berjot, contain 34 per cent. (*Journ. de Pharm.*, Avril, 1863, p. 277.) In its preparation on a large scale, the seeds are usually roasted before being pressed, in order to destroy the gummy matter contained in their coating. The oil is thus obtained more free from mucilage, but more highly coloured and acrid than when procured by cold expression. For medical use, therefore, it should be prepared without heat; and, as it is apt to become rancid quickly on exposure, should be used as soon after expression as possible. It may, however, be rendered sweet again by agitation with warm water, rest, and decantation. It is said to be obtained purer and in larger proportion by treating the crushed seeds with bisulphide of carbon, than by expression. (See *Am. Journ. of Pharm.*, xxvi. 265.) Flaxseed oil has a yellowish-brown colour, a disagreeable odour, and a nauseous somewhat acrid taste; is of the sp. gr. 0·932; boils at 600° F.; does not congeal at zero; dissolves in forty parts of cold and five of boiling alcohol, and in one part and a half of ether; and has the property of drying, or becoming solid on exposure to the air. The drying property resides in its fluid constituent, which, to distinguish it from the olein of the non-drying oils, is named *linolein*. Its acrimony is owing to the presence of a small proportion of an acrid oleoresin. From its drying property, it is useful in painting, and the formation of printers' ink.*

Medical Properties and Uses. It is laxative in the dose of a fluidounce; but on account of its disagreeable taste is seldom given internally. It has, however, been highly recommended as a cure for piles, in the dose of two ounces of the fresh oil morning and evening. It is sometimes added to purgative enemata; but its most common application is externally to burns, usually in combination with lime-water.†

W.

OLEUM MORRHUÆ. *U.S., Br.*

Cod-liver Oil.

A fixed oil obtained from the liver of Gadus Morrhua and of other species of Gadus. *U. S.* The oil extracted from the fresh liver of the cod by the application of a heat not exceeding 180°. *Br.*

* *Linoleum.* This name has been given to preparations of flaxseed oil, having certain physical properties, which adapt it to many of the purposes for which caoutchouc is used. It is made by incorporating, with a strong heat, the oil converted by the oxidation of the drying process into a semi-resinous substance with resinous gums and other bodies. (See *Am. Journ. of Pharm.*, July, 1866, p. 372.)

† *Oiled Paper.* A substitute for waxed cloth, for the dressings of wounds and ulcers, prepared in the following manner by M. Gauthier, of Geneva, with flaxseed oil, has been highly recommended. To facilitate its drying, 3 litres (about 6·4 pints) of the oil are boiled for an hour or two with 30 grains of acetate of lead, 30 grains of litharge, 15 grains of yellow wax, and 15 grains of turpentine. Thus prepared, the oil is spread upon silk-paper by means of a brush on both surfaces. On the top of the first sheet another is then placed so as to overlap it at one corner. The lower surface of the second sheet thus becomes impregnated with the oil, which now requires to be applied only to the upper. Any desired number of sheets may be thus successively superimposed. They are then separated, and suspended in a drying apartment, attached to a cord by means of hooks or pins. When dry, they should be sprinkled over with chalk to prevent adhesion, and packed away. (*Journ. de Pharm.*, Mai, 1860, p. 363.)—*Note to the twelfth edition.*

Oleum jecoris Aselli; Huile de morue, *Fr.;* Stockfischleberthran, *Germ.*

GADUS. *Class* Pisces. *Order* Jugulares. *Linn.* Malacopterygii Subbrachiati. *Family* Gadidæ. *Cuvier.*

Gen. Ch. Recognised by the ventrals attached under the throat, and attenuated to a point.

Gadus Morrhua. Linn. *Syst. Nat. ed. Gmelin*, i. p. 1162; Cuvier, *Règne Animale*, ii. 212; Bloch. *Ichthyologie*, pl. lxiv.—*Morrhua vulgaris.* Storer, *Synops. of Fishes of N. Am.*, p. 216. The *common cod* is between two and three feet long, with brown or yellowish spots on the back. The body is moderately elongated and somewhat compressed, and covered with soft rather small scales, of which the head is destitute. Of the fins, which are soft, there are three on the back, two anal, and a distinct caudal; and the fin under the throat is narrow and pointed. The jaws are furnished with pointed irregular teeth, in several ranks. The gills are large, with seven rays. This species of cod inhabits the Northern Atlantic, and is especially abundant on the banks of Newfoundland, where it finds food adapted to its wants.

Besides the common cod, several other species of Gadus, frequenting the seas of Northern Europe and America, contribute to furnish the cod-liver oil of commerce. Among these De Jongh mentions *Gadus callarias* or *dorsch* (*Morrhua Americana* of Storer), *G. molva* or *ling*, *G. carbonarius* or *coal fish*, and *G. pollachius* or *pollock*, as affording the oil on the coast of Norway;* while, from information obtained by Professor Procter, there is reason to believe that, on our own coast, in addition to the pollock above mentioned, it is obtained also from the *hake* (*G. merluccius*) and the *haddock* (*G. Æglifinus*). It is said that 24,000 gallons of the oil are obtained annually on our coast between Boston and Eastport, in Maine, in reference to the drug market. (See *Am. Journ. of Pharm.*, Nov. 1859, p. 500.)

Preparation. Fishermen have long been in the habit of collecting this oil, which is largely consumed in the arts, particularly in the preparation of leather. Upon the coasts of Newfoundland, Nova Scotia, and New England, the boats which fish near the shore, being small, soon obtain a load, and running in to land, deliver their cargoes to persons whose business it is to cleanse and salt the fish. The oil is prepared either in the huts of the fishermen, or more largely at establishments to which the livers are conveyed in quantities. These are put into a boiler with water, and heated until they are broken up into a pultaceous mass, which is thrown upon a strainer covering the top of a cask or tub. The liquid portion passes, and upon standing separates into two parts, the oil rising to the surface of the water. The oil is then drawn off, and, having been again strained, is prepared for the market. Another and improved method, which has come into use since the extensive employment of the oil as a medicine, is to heat the livers in a large tin vessel by means of steam externally applied. The pultaceous mass resulting is drained as before mentioned; the livers themselves containing, besides oil, a considerable portion of watery fluid, which passes off with it in the form of emulsion, and separates on standing. The oil thus procured is called *shore oil*, and is the purest kind. The crews of the larger boats, which fish upon the banks far from land, cleanse the fish on board, and, throwing the offal into the sea, put the livers into barrels or other receptacles, where they undergo a gradual decomposition, the oil rising to the surface, as it escapes from the disintegrating tissue. The oil which first rises, before putrefaction has very decidedly commenced, approaches in purity to the shore oil, but is somewhat darker and less sweet. This is sometimes drawn off, constituting the *straits oil* of the fishermen. The remaining mass, or the whole, if the portion which first rises be not separated, continues exposed for a variable length of time to the

* For an account of the mode of fishing for cod and of preparing the oil practised in Norway, the reader is referred to an interesting article, by Mr. Robert Howden, in the *Pharm. Journ. and Trans.* (Jan. 1868, p. 312). A paper on the preparation of the oil in Denmark, by M. J. Leon Soubeiran, will be found in the *Journ. de Pharm. et de Chim.* (4e sér., iv. 324, A. D. 1866).

heat of the sun, undergoing putrefaction, until the boat, having completed her cargo, returns to port. The contents of the casks are then put into boilers, heated with water, and treated as already described. Before being finally put into barrels, the oil is heated to expel all its water. Thus prepared, it is denominated *banks oil*, and is of the darkest colour, and most offensive to the taste and smell. Much of the oil prepared by the fishermen is collected by the wholesale dealers, who keep it in very large reservoirs of masonry in their cellars, where it becomes clarified by repose, and is pumped into barrels as wanted for sale. By the further exposure, however, which it thus undergoes, it acquires a still more offensive odour; while that which has been originally introduced into barrels, and thus kept secluded from the air, is better preserved. The above facts in relation to the collection of cod-liver oil have been mainly derived from a very interesting paper by Professor Procter, in the *Am. Journ. of Pharm.* (xxiii. 97). To the same journal (xxvi. 1) the reader is referred for an account, by Dr. E. H. Robinson, of Nova Scotia, of the method in which the oil is prepared by the fishermen of that Province.

The oil is sometimes procured by expression. Mr. Donovan recommends the following plan, which affords a very fine oil. The livers, perfectly sound and fresh, are to be placed in a clean iron pot over a slow fire, and stirred until they assume the condition of a pulp, care being taken that the mass be not heated beyond 192°. When this temperature is attained, the pot is to be removed from the fire, and its contents introduced into a canvas bag, through which water and oil will flow into a vessel beneath. After twenty-four hours, the oil is to be decanted and filtered through paper. In this state it is pale-yellow, with little odour, and a bland not disagreeable taste.

Properties. Three varieties of cod-liver oil are known in the market, the *white* or *pale-yellow*, the *brownish-yellow*, and the *dark-brown*, corresponding to the three commercial varieties already alluded to. These differ in no essential character, but simply from the mode of preparation; the pale being prepared from fresh sweet livers, the dark-brown from livers in a state of putrefaction, and the brownish-yellow from those in an intermediate state; and the three varieties run together by insensible shades. The colour of the pale is from the slightest tint of transparent yellow to a fine golden yellow, that of the light-brown very similar to the colour of Malaga wine, that of the dark-brown what its name implies, with opacity in mass, but transparency in thin layers. They are of the usual consistence of lamp-oil, and have a characteristic odour and taste, by which they may be distinguished from other oils. This smell and taste are familiar to most persons, being very similar to those of shoe-leather; at least as prepared in this country, where the curriers make great use of cod-liver oil. We regard these sensible properties as the most certain test of the genuineness of the oil. They are much less distinguishable in the pale than in the dark-brown varieties, but we have met with no specimen which did not possess them in some degree. In the purest they are scarcely repulsive, in the dark-brown they are very much so. When a decided smell of ordinary fish-oil is perceived, the medicine may always be suspected. It is quite distinct from that peculiar to the cod-liver oil. The taste of all the varieties is more or less acrid, and in the most impure is bitterish and somewhat empyreumatic. The sp. gr. at 72° F., as ascertained by Prof. Procter, varied from 0·915 to 0·9195; the first being that of the *hake* oil, the second that of the *haddock*, while the sp. gr. of the purest oil from the common cod was 0·917. De Jongh found the sp. gr. at 63° F., of the pale 0·923, of the light-brown 0·924, of the dark-brown 0·929. The oil from the cod does not congeal at 14° F., though that of G. carbonarius and that of the livers of different species of Raja, let fall at that temperature a solid fatty matter, supposed to be margarin. Alcohol dissolves from 2·5 to 6 per cent., water from 0·637 to 1·28 per cent. of different varieties; the pale yielding least to these solvents. (*Journ. de Pharm.*, Jan. 1854, p. 39.)

From an analysis of the oil by De Jongh, it appears to consist of a peculiar substance named gaduin; oleic and margaric acids with glycerin; butyric and

acetic acids; various biliary principles, as fellinic, cholic, and bilifellinic acids, and bilifulvin; a peculiar substance soluble in alcohol; a peculiar substance insoluble in water, alcohol, or ether; iodine, chlorine, and traces of bromine; phosphoric and sulphuric acids; phosphorus, lime, magnesia, soda, and iron. These were found in all the varieties, though not in equal proportion in all; yet it is quite uncertain whether the difference had any relation to their degree of efficacy. *Gaduin* is obtained by saponifying the oil with soda, decomposing the soap by acetate of lead, and treating the resulting lead soap with ether, which dissolves the oleate of lead and gaduin, leaving the margarate of lead behind. The ethereal solution, which is dark-brown, is decomposed by sulphuric acid, which liberates the brown oleic acid. This owes its colour to gaduin, to separate which soda is added in excess. The resulting oleate of soda, which is insoluble in an excess of the alkali, is dissolved in alcohol; and the alcoholic solution is cooled below 32°, by which means the oleate of soda is separated, the gaduin remaining in solution. This is precipitated from its solution by the addition of sulphuric acid. Gaduin is a dark-brown substance, brittle and pulverizable when dry, without odour or taste, quite insoluble in water, and in great measure soluble in ether and alcohol. It is insoluble in nitric and muriatic acids, but is dissolved by sulphuric acid, giving a blood-red colour to the solution, from which it is precipitated by water and the alkalies. It is soluble in alkaline solutions. Chlorine decolorizes it. Its formula is $C_{35}H_{23}O_9$. Gaduin itself is yellow, but becomes brown by exposure to the air. It has not been ascertained to be in any degree connected with the virtues of the oil. It is not improbable that the biliary principles associated with the oil are concerned in its peculiar influences; as it is by their presence mainly that this differs from other oils. It has been thought that gaduin itself is of biliary origin. Winckler has inferred from his researches that cod-liver oil is an organic whole, differing from all other fixed oils. Thus, it yields no glycerin upon saponification, but, in place of it, a peculiar body which he denominates oxide of propyl. The fatty acids generated are the oleic and margaric. Dr. Luck has found a peculiar fatty acid in turbid oil, which he names *gadic acid*, and the same is obtained from the clear oil by saponification. (*Neues Jahrbuch für Pharm.*, vi. 249.) By reaction with ammonia in distillation, the oil yields a peculiar volatile alkali, called *propylamin*, which has a strong pungent odour, recalling that of herring-pickle, of which the same alkali is an ingredient. No other officinal fatty oil yields a similar product. (See *Am. Journ. of Pharm.*, xxiv. 343.) Some have been disposed to ascribe the virtues of the oil to its iodine and bromine; but these are in too small proportion for much effect, and the oil has produced results which have never been obtained from iodine and bromine themselves. The presence of iodine cannot be detected by the usual tests. It is necessary to convert the oil into a soap, and to carbonize this before it will give evidence of iodine. The proportion never exceeds 0·05 per cent., or 1 part in 2000. The oil is capable of dissolving a larger proportion; and, if any specimen contain more, there is reason to suspect that it has been fraudulently added.

Tests of Purity. In consequence of the great demand for this oil, it has not unfrequently been adulterated with other fixed oils, and occasionally others have been fraudulently substituted for it. The importance, therefore, is obvious of ascertaining some mode of testing its purity and genuineness. There is reason to believe that all the oils from the livers of the Gadidæ have analogous properties. They have been indiscriminately used; and upon the results of their employment is based, in part, the present reputation of the medicine. They may, therefore, be considered as in fact one oil, so far as their medicinal use is concerned. Unfortunately chemistry has yet discovered no perfectly reliable test. The furthest it has yet gone is to point out certain reactions, which may be considered as evidences of the presence of biliary principles in the oil, thus indicating its hepatic origin. Among these probably the most characteristic is that of sulphuric acid, a drop of which, added to fresh cod-liver oil, on a porcelain plate, causes a centrifugal movement in the oil, and gives rise to a fine

violet colour, soon passing into yellowish or brownish-red. Sometimes, instead of assuming the violet hue, the colour immediately becomes a clear red, or dark brownish-red. This is said to be especially the case with those specimens of the oil which have been prepared by boiling the livers with water. Shark-liver oil responds in like manner to the test of sulphuric acid, but is said to have the sp. gr. 0·866, which is much lower than that of any variety of the genuine oil. Strong nitric acid causes instantly, when agitated with cod-liver oil, a pinkish or rose-red colour, which soon becomes brown; while no such effect is produced on other animal or vegetable oils. According to Winckler, the oil should afford the smell of herring-pickle when heated with potassa, lime, and muriate of ammonia. But the most reliable tests are the sensible properties of odour and taste. If there be none of the peculiar shoe-leather smell and taste, or if a strong lamp-oil odour be perceptible, the oil may be suspected. Little of importance can be inferred from the colour. Some have been disposed to prefer the dark offensive oil; but our own experience accords with that of those who have found the pale or light-brown equally efficient; and, for facility of administration and acceptability to the stomach, the latter is greatly preferable.

It is important that the oil should be secluded from the air, which effects a gradual change, no doubt impairing its efficiency. Hence the vessels containing it should be full; and apothecaries ought to keep it in bottles well stopped, holding about the quantity generally wanted for use at one time.

Medical Properties and Uses. Cod-liver oil has been long popularly employed in northern Europe in rheumatic and strumous diseases. It was first brought to the notice of the profession generally by German practitioners, and had acquired great reputation on the continent before it was used to any extent in Great Britain. At Manchester, in England, it was employed by the medical profession in the treatment of chronic rheumatism and gout, as early as 1766; but it was not until the appearance of the treatise of Professor Bennett, of Edinburgh, in 1841, that it came into general notice in Great Britain and the United States. It is at present one of the most esteemed remedies in the catalogue of the Materia Medica. The diseases in which it has proved most efficient are chronic rheumatism and gout, and the various morbid affections connected with a scrofulous diathesis, such as external glandular scrofula, diseases of the joints and spine, carious ulcers, tabes mesenterica, rickets, and phthisis. It has been found useful also in chronic cutaneous eruptions, lupus, ulcers of the mouth, some varieties of palsy, chronic pectoral complaints not tuberculous, pertussis, obstinate constipation, intestinal worms, and incontinence of urine; and may be employed with the hope of good in all chronic cases in which the disease appears to consist mainly in impaired digestion, assimilation, and nutrition. In pulmonary consumption, in the experience of the author, it has far exceeded in efficacy any other remedy or combination of remedies that he has hitherto employed. It is necessary, however, to persevere for four or six weeks before looking for any decidedly favourable results, though the change does often begin earlier. In most cases remarkable temporary relief is afforded; in many, the disease is favourably modified, and its fatal termination postponed; and in some, cures appear to have been effected.

As to its mode of action, there has been much difference of opinion. Some consider it merely as a nutritive agent, having the advantage over other oleaginous substances, of a readier entrance into the system, and more easy assimilation. But we cannot agree with this opinion. Other oleaginous substances, certainly not less nutritious, have not been equally efficient, though taken in much larger quantities. If this be the true explanation, persons living chiefly on milk which abounds in oil, or on fat pork, ought to show a special exemption from scrofulous complaints. The probability appears to us to be that, in consequence of some peculiar principle or principles it contains, it exercises a stimulant and alterative influence on the processes of assimilation and nutrition; thereby causing the production of healthy tissue, instead of that abortive material which is deposited by the blood-vessels in scrofula and phthisis. With

our views of the modus operandi of cod-liver oil, it would of course be contra-indicated in all cases where there is existing plethora, or a strong tendency to it. The medicine has been accused of having occasionally produced serious congestion of the lungs.

The dose is a tablespoonful three or four times a day for adults, a teaspoonful repeated as frequently for children, which may be gradually increased as the stomach will permit, and continued for a long time. It may be taken alone, or mixed with some vehicle calculated to conceal its taste, and obviate nausea. For this purpose recourse may be had to any of the aromatic waters, to the aromatic tinctures, as the tincture of orange-peel, diluted with water, or to a bitter infusion, as that of quassia. It may be given floating on the vehicle, or mixed with it by means of gum or the yelk of eggs, with sugar, in the form of an emulsion. Perhaps the best vehicle, when not contraindicated, is the froth of porter. Let a tablespoonful of porter be put into the bottom of a glass, upon the surface of this the oil, and over all some of the froth of the porter. A small piece of orange-peel may be chewed before and after taking the medicine. Various other methods have been adopted to conceal or correct its taste, and favour its administration. Common salt has been recommended; but nothing, perhaps, so effectually destroys the taste as oil of bitter almonds, of which one part will answer for 200 parts of the oil; but a better plan is to shake strongly, in a flask, one measure of the oil with from one to two of cherry-laurel water, according to the degree of offensiveness, and to separate the liquids after they have been allowed to stand for twenty-four hours. The oil should be filtered if not quite clear. The medicine has sometimes also been given in capsules; but this must be a very tedious method. M. Dufourmantel prepares a jelly by dissolving half a drachm of ichthyocolla in as little hot water as possible, and then gradually mixing with it a fluidounce of the oil with four drops of the oil of anise, taking care not to exceed the heat of 75° F. (*Journ. de Pharm.*, Juin, 1864, p. 72.) The oil is sometimes applied externally by friction, and, in cases of ascarides or lumbricoides, is injected into the rectum. It has been recommended locally in chronic articular affections, paralysis, various chronic cutaneous eruptions, and in opacity of the cornea after the subsidence of inflammation. In the last-mentioned affection, one or two drops of the oil are applied by means of a pencil to the cornea, and diluted, if found too stimulating, with olive or almond oil. It is said, when long used internally, to occasion sometimes an exanthematous or eczematous eruption.*

* *Cod-liver Oil with Iodide of Iron.* A preparation of cod-liver oil, in which the oil was supposed to hold iodide of iron in solution, has been considerably used in Europe, under the impression that such a combination is more efficient in scrofulous states of the system than the pure oil. But M. Rabourdin, of Orléans, France, showed that the preparation, as found in the shops, often contains no iron; and his results were confirmed by M. Sinimberghi, a pharmaceutist of Rome, who states that the oil sold as containing iodide of iron was, in several specimens examined by him, not only destitute of iron, but was altered in colour, had a noxious taste and smell, was more or less thickened, and was in fact unfit for use. He proposes the following formula, which he says yields a limpid preparation, differing but little in colour, taste, and odour from the pure oil, does not change on keeping, and yet contains four grains of iodide of iron in a fluidounce. Taking 1000 parts of the pure oil, he separates 30 parts, and adds to this portion 12 parts of pure ether. Shaking the mixture, which is exposed to a slight increase of temperature, he sets it aside for the moment, and then rubs together in a porcelain mortar 6·5 parts of pure protosulphate of iron and 5·15 parts of perfectly pure iodide of potassium, and during the trituration adds 1 part of reduced iron to neutralize any iodine that may be set free, and a little pure glycerin to moisten the mixture. When the double decomposition has taken place, which is usually completed in two minutes, he gradually adds to the mixture one-third of etherized oil prepared as above, and one-third of the original cod-liver oil remaining, and, mixing these well together, fills with the mixture a glass bottle, which is kept well closed till the precipitate has subsided. The clear oil is then poured off, and the process is repeated a second and a third time by adding a second and third portion of the etherized oil and pure oil to the precipitate. The whole is now put into a bottle which it precisely fills, and, having been allowed to stand ten days, is filtered, and kept in well-stopped bottles. (*Pharm. Journ. and Trans.*, 2d ser., viii. 277.)

Ferruginous Cod-liver Oil. M. Ricker prepares this medicine as follows. Having sa-

The *olein* of cod-liver oil has been recommended by Dr. Arthur Leared, when the oil itself disagrees with the stomach. He has found it to produce the same remedial effects, and to be much better borne. It may be given in the same dose. A *solution of quinia in the oil* has been proposed in cases where the two medicines are jointly indicated. It may be made by adding the freshly precipitated alkaloid to the oil, in the proportion of two grains to a fluidounce, and heating them together, by means of a water-bath, until the mixture becomes quite clear.

It has been thought that the efficacy of cod-liver oil is greatly enhanced by augmenting the proportion of certain active principles naturally contained in it; and a preparation of this kind, known as *Fougera's cod-liver oil*, each pint of which contains eight grains of iodine, one grain of bromine, and one of phosphorus, has been extensively used in this country, and is highly praised in some of our journals. (*Med. and Surg. Reporter*, May 2, 1868, p. 397.)* W

OLEUM MYRISTICÆ. *U. S., Br.*

Oil of Nutmeg. Volatile Oil of Nutmeg.

ponified 100 parts of the oil with 70 parts of solution of soda of the sp. gr. 1·33, he adds to the soap 100 parts of a solution of common salt of 25 to 100. The mixture is placed upon a cloth and expressed. Of the residue 60 parts, dissolved in 500 of distilled water, are precipitated by a solution of 15 parts of sulphate of iron in 100 of water. The insoluble ferruginous precipitate which forms is washed upon a linen cloth and expressed. The process is completed by dissolving 30 parts of this soap in 500 of cod-liver oil, and filtering. The resulting oil is of a brown colour, and 30 parts contain 62 thousandths of one part of iron, equivalent to about three grains to a pint. (*Journ. de Pharm. et de Chim.*, 4e sér., v. 57, A. D. 1857.)

Extract of Cod Liver. Under the name of *Geoffroy's Dragées of Cod-liver Extract*, a medicine has been patented in England, and recently attracted some attention, consisting essentially of an extract obtained by evaporating the watery liquid which escapes from the cod liver when the oil is extracted. Mr. Squire obtained one pound of this watery fluid from twenty-eight pounds of the liver, and by its evaporation 12 per cent. of extract. Mr. John Barr, one of the patentees, states that livers properly treated yield much more watery liquid than here stated, and that the liquid gives 15 per cent. of extract. Now, if, as some suppose, the virtues of cod-liver oil depend upon principles extracted with it from the liver independently of the pure oil, there is every reason to believe that these principles exist to a certain extent in the watery fluid referred to, and consequently that the preparation under consideration may have important powers, and prove highly useful as a medicine. This, however, is a point to be determined only by experience; and all that can be said at present is that the medicine is worthy of a trial. The following is given as the chemical constitution of the extract; in 100 parts 60·62 of fish-bile constituents, 2·545 of propylamin, 6·0 of acetic, lactic, and butyric acids, 2·09 of phosphorus and phosphoric acid, 0·2 of sulphur and sulphuric acid, 0·154 of iodine, 1·525 of chlorine with a trace of bromine, 1·17 of soda, 0·366 of magnesia, 0·510 of lime, 0·211 of potassa, 2·862 of ammonia, and 21·847 of water, including loss. Five grains of the extract are announced as equal in medicinal virtues to a tablespoonful of cod-liver oil. It is prepared for use in the form of pills, which consist of six parts of the extract, five of cacao butter, and one of sugar. (*Chem. News*, Dec. 1, 1865, p. 264, and Jan. 5, 1866, p. 10.)

Cleansing Cod-Liver Oil Bottles. Prof. Procter has found benzine the best material for this purpose, with the addition of pearlash, lime, and boiling water. The practical pharmaceutist is referred for the details of the process to the *Am. Journ. of Pharm.*, Nov. 1868, p. 509. (*Notes to the thirteenth edition.*)

* *Dugong Oil.* An oil has been brought into notice, as a substitute for cod-liver oil, obtained from two species of *Halecore*, *H. Australis* (*Owen*) and *H. Dugong* (*Illig.*), cetaceous animals inhabiting the rivers and bays of Northern and Eastern Australia, and many of the East India islands. The flesh of these animals is said to be delicate and palatable, and valued for food. The oil is obtained by boiling the superficial fat. It is bland and sweet, and free from disagreeable taste and smell, so that it may be taken more freely than cod-liver oil, which it is thought to equal in virtues. It was introduced into use by Mr.

This oil is obtained from powdered nutmegs by distillation with water. A better method, according to M. J. Cloez, who has carefully examined the subject of oil of nutmeg, is to exhaust the powder with bisulphuret of carbon or ether, distil off the solvent by means of a water-bath, and expose the butter-like residue to a current of steam, the vapour being conveyed into a refrigerated receiver where it condenses. (*Journ. de Pharm.*, Fév. 1864, p. 150.) Oil of nutmeg is colourless or of a pale-straw colour, limpid, lighter than water, soluble in alcohol and ether, with a pungent spicy taste, and a strong smell of nutmeg. The sp. gr. is stated differently at 0·920 and 0·948. It consists of two oils, which may be separated by agitation with water, one rising to the surface, the other sinking to the bottom. Upon standing it deposits a crystalline stearoptene, which is called by John *myristicin*. M. Cloez found that, when the oil was distilled at a temperature below 347° F., there came over 95 per cent. of a liquid, which, when treated with a little caustic potassa and subsequently distilled from a little sodium, in order to separate traces of a compound of oxygen, was a pure colourless carbohydrogen, remaining liquid at zero of F., of the sp. gr. 0·853 at 59° F., and corresponding in composition with pure oil of turpentine, having the formula $C_{20}H_{16}$. It differs, however, in yielding, when acted on by a current of muriatic acid gas, a liquid instead of solid compound with the acid. In this purified state the oil has an odour recalling that of nutmeg, but, when the oil is diluted, approaching to that of the oil of lemons. It absorbs oxygen slowly, losing its fluidity. Chlorine and bromine act on it vigorously, nitric acid violently with the disengagement of red vapours, and concentrated sulphuric acid dissolves and darkens it. (*Ibid.*, p. 150–2.) The oil may be used for the same purposes as nutmeg, in the dose of two or three drops; but is not often employed.

Olea Europæa. Willd. *Sp. Plant.* i. 44; Woodv. *Med. Bot.* p. 280, t. 98. This valuable tree is usually from fifteen to twenty feet in height, though sometimes much larger, especially in Greece and the Levant. It has a solid, erect, unequal stem, with numerous straight branches, covered with a grayish bark. The leaves, which stand opposite to each other on short footstalks, are evergreen, firm, lanceolate, entire, two or three inches in length, with the edges somewhat reverted, smooth and of a dull-green colour on their upper surface, whitish and almost silvery beneath. The flowers are small, whitish, and disposed in opposite axillary clusters, about half as long as the leaves, and accompanied with small, obtuse, hoary bractes. The fruit or olive is a smooth, oval drupe, greenish at first, but of a deep-violet colour when ripe, with a fleshy pericarp, and a very hard nut of a similar shape. Clusters of not less than thirty flowers yield only two or three ripe olives.

The olive tree, though believed by some to have been originally from the Levant, flourishes at present in all the countries bordering on the Mediterranean, and has been cultivated from time immemorial in Spain, the south of France, and Italy. It begins to bear fruit after the second year, is in full bearing at six years, and continues to flourish for a century. There are several varieties, distinguished by the form of the leaves, and the shape, colour, and size of the fruit.

W. Hobbs, a surgeon of Brisbane, on Moreton Bay. (*Chem. News*, Jan. 28, 1860, p. 87, and *Am. Journ. of Pharm.*, July, 1858, p. 335, and May, 1860, p. 230.)—*Note to the twelfth edition.*

The variety *longifolia* of Willdenow is said to be chiefly cultivated in Italy and the south of France, and the *latifolia* in Spain. The latter bears much larger fruit than the former; but the oil is less esteemed.

The leaves and bark of the olive tree have an acrid and bitterish taste, and have been employed as substitutes for cinchona, though with no great success. Attention has recently been called, in France, to a hydro-alcoholic extract of the leaves, as having considerable febrifuge powers. In the quantity of from ten to twenty grains daily, in divided doses, it has been found useful in preventing the hectic paroxysms. In hot countries, a substance resembling the gum-resins exudes spontaneously from the bark. It was thought by the ancients to possess useful medicinal properties, but is not now employed. Analyzed by Pelletier, it was found to contain resin, a little benzoic acid, and a peculiar principle analogous to gum, which has been named *olivile*. But the fruit is by far the most useful product. In the unripe state it is hard and insupportably acrid; but, when macerated in water or an alkaline solution, and afterwards introduced into a solution of common salt, it loses these properties, and becomes a pleasant and highly esteemed article of diet. Mannite has been found in all parts of the tree while in vital activity, as in the green leaves and unripe fruit, but cannot be detected in the yellow fallen leaves, nor in the perfectly ripe fruit. (*Am. J. of Pharm.*, March, 1866, p. 179.) The pericarp, or fleshy part of the ripe olive, abounds in a fixed oil, which constitutes its greatest value, and for which the tree is chiefly cultivated in Southern Europe. In the unripe olive a peculiar green substance, together with mannite, has been found by M. S. de Lutz, both of which disappear as the fruit ripens, being probably converted into oil, which now takes their place. (*Journ. de Pharm.*, Juin and Déc. 1862.) The oil is obtained by first bruising the olives in a mill, and then submitting them to pressure. The product varies much, according to the state of the fruit, and the circumstances of the process. The best, called *virgin oil*, is obtained from the fruit picked before perfect maturity, and immediately pressed. It is distinguished by its greenish hue. The common oil used for culinary purposes, and in the manufacture of the finest soaps, is procured from very ripe olives, or from the pulp of those which have yielded the virgin oil. In the latter case the pulp is thrown into boiling water, and the oil removed as it rises. An inferior kind, employed in the arts, especially in the preparation of the coarser soaps, plasters, unguents, &c., is afforded by fruit which has been thrown into heaps, and allowed to ferment for several days, or by the *marc* left after the expression of the finer kinds of oil, broken up, allowed to ferment, and again introduced into the press. The remarks made under the head of Oleum Myristicæ (*page* 605), in relation to the extraction of that oil by means of bisulphuret of carbon, are applicable also to olive oil.

Olive oil is imported in glass bottles, or in flasks surrounded by a kind of network of grass, and usually called Florence flasks. The best comes from the south of France, where most care is exercised in the choice of the fruit.

Properties. The pure oil is an unctuous liquid, of a pale-yellow or greenish-yellow colour, with scarcely any smell, and a bland, slightly sweetish taste. Its sp. gr. is 0·9153. It is soluble in twice its volume of ether, but is only partially soluble in alcohol, at least unless this liquid be in very large proportion. It begins to congeal at 38° F. At a freezing temperature a part of it becomes solid, and the remainder, retaining the liquid consistence, may be separated by pressure, or by the agency of cold alcohol, which dissolves it. The concrete portion has been found by MM. Pelouze and Boudet to be a definite compound of margarin and olein; the liquid portion is uncombined olein. According to Braconnot, the oil contains 72 per cent. of olein, and 28 of margarin. Olive oil is solidified by nitrous acid and nitrate of mercury, and converted into a peculiar fatty substance, called *elaïdin*. The olein of all oils which have not the drying property undergoes the same change, when acted on by nitrous acid; and the singular fact is stated by MM. Pelouze and Boudet, that the margarin of olive oil, combined as it is with olein, is converted by that acid into elaïdin, while the

same principle, in a state of purity, is not affected by it. (*Journ. de Pharm.*, xxiv. 391)*

Olive oil, when exposed to the air, is apt to become rancid, acquiring a disagreeable smell, a sharp taste, a thicker consistence, and a deeper colour; and the change is promoted by heat. It is frequently adulterated with the cheaper fixed oils, especially with that of poppies; but the adulteration may be easily detected by reducing the temperature to the freezing point. As other oils are less readily congealed than the olive oil, the degree of its purity will be indicated by the degree of concretion. Another mode has been indicated by M. Poutet, founded on the property possessed by supernitrate of mercury of solidifying the oil of olives, without a similar influence upon other oils. Six parts of mercury are dissolved at a low temperature in seven and a half parts of nitric acid of the sp. gr. 1·35; and this solution is mixed with the suspected oil in the proportion of one part to twelve, the mixture being occasionally shaken. If the oil is pure, it is converted after some hours into a yellow solid mass; if it contains a minute proportion, even so small as a twentieth, of poppy oil, the resulting mass is much less firm; and a tenth prevents a greater degree of consistence than oils usually acquire when they concrete by cold. M. Gobel has invented an instrument which he calls the elaïometer, by which the smallest quantity of poppy oil can be detected. (See *Am. Journ. of Pharm.*, xvi. 24.) According to M. Marchand, strong sulphuric acid produces with poppy oil a lemon-yellow colour, which rapidly becomes darker, and, after ten or fifteen minutes, is followed by tints of rose-colour and bright violet, which are never afforded with the same reagent by pure olive oil. (*Ibid.*, xxvi. 432.) The presence of colza oil may be detected by the test of nitrate of silver, as stated under the head of Oleum Amygdalæ Dulcis (*page* 591). M. Diesel states that the pure oil is coloured green by common nitric acid; whereas, if mixed with rape oil, it is rendered of a yellowish-gray colour. (*Arch. der Pharm.*, xlvi. 287.) According to M. Behrens, whose statement is confirmed by MM. Guibourt and Reveil, the presence of oil of sesamum is known by the beautiful deep-green colour immediately produced, when the suspected oil is added, in equal weight, to a mixture of equal parts of sulphuric and nitric acids; which acids cause with the pure oil, at first, a bright-yellow colour. (*Journ. de Pharm.*, 3e sér., xxiv. 351.) Immense quantities of lard oil are said to be exported from this country to France, and employed in the adulteration of olive oil. The reaction with nitric acid would probably serve to detect this adulteration, which, however, in a pharmaceutical point of view, is of little inconvenience.

M. A. Lailler, a French pharmaceutist, has found in the joint action of chromic and nitric acids a test by which he believes that olive oil can be distinguished from most other oils. If a mixture of two parts of liquid chromic acid at the eighth, and one of nitric acid of 40°, in the quantity of 30 grains, be agitated in a glass tube with two drachms of olive oil, there will be no oxidation nor any disengagement of heat, but at the end of forty-eight hours, at most, a beginning of concretion, which in some days becomes complete, and is followed by the entire absorption of the reagent by the oil and a blue coloration of the latter. Every specimen of olive oil which does not present these phenomena completely must be considered as falsified. (*Journ. de Pharm. et de Chim.*, 4e sér., i. pp. 187–8.)

Medical Properties and Uses. Olive oil is nutritious and mildly laxative, and is occasionally given in cases of irritable intestines, when the patient objects to more disagreeable medicines. Taken into the stomach in large quantities, it serves to involve acrid and poisonous substances, and mitigate their action. It

* The following table gives the solubility of various alkaloids in olive oil as ascertained by Pettenkoffer. At the ordinary temperature, 100 parts of the oil dissolve of

(*Journ. de Pharm.*, Juin, 1859, p. 486.)—*Note to the twelfth edition.*

has also been recommended as a remedy for worms, and is a very common ingredient in laxative enemata. Externally applied, it is useful in relaxing the skin, and sheathing irritated surfaces from the action of the air; and is much employed as a vehicle or diluent of more active substances. In the countries bordering on the Mediterranean, it is thought, when smeared over the skin, to afford some protection against the plague; and applied warm, by means of friction over the surface, is said to be useful as a remedy in the early stages of that complaint. But the most extensive use of olive oil is in pharmacy, as a constituent of liniments, ointments, cerates, and plasters.

The dose as a laxative is from one to two fluidounces.

Ricinus communis. Willd. *Sp. Plant.* iv. 564; Woodv. *Med. Bot.* p. 624, t. 221. The castor oil plant, or *palma Christi*, attains in the East Indies and Africa the character of a tree, and rises sometimes thirty or forty feet. In the temperate latitudes of North America and Europe it is annual; though M. Achille Richard saw, in the south of France, in the vicinity of Nice, on the seacoast, a small wood consisting entirely of what he supposed to be this species of Ricinus.* The following description applies to the plant as cultivated in cool latitudes. The stem is of vigorous growth, erect, round, hollow, smooth, glaucous, somewhat purplish towards the top, branching, and from three to eight feet or more in height. The leaves are alternate, peltate or supported upon footstalks inserted into their lower disk, palmate with seven or nine pointed serrate lobes, smooth on both sides, and of a bluish-green colour. The flowers are monœcious, stand upon jointed peduncles, and form a pyramidal terminal raceme, of which the lower portion is occupied by the male flowers, the upper by the female. Both are destitute of corolla. In the male flowers the calyx is divided into five oval, concave, pointed, reflected, purplish segments; and encloses numerous stamens, united into fasciculi at their base. In the female the calyx has three or five narrow lanceolate segments; and the ovary, which is roundish and three-sided, supports three linear, reddish stigmas, forked at their apex. The fruit is a roundish glaucous capsule, with three projecting sides, covered with tough spines, and divided into three cells, each containing one seed, which is expelled by the bursting of the capsule.

This species of Ricinus is a native of the East Indies and Northern Africa,

* While at Montpellier, in France, in the spring of 1861, the author was assured by Dr. Martius, Professor of Botany in the University of that city, that the species seen by Richard, forming a grove in the south of France, was not, as believed by that botanist, the Ricinus communis, but the *Ricinus Africanus*. This Prof. Martius knew from personal observation; and he stated, moreover, that all the plants of the genus Ricinus growing wild on the borders of the Mediterranean were of this species, viz., the R. Africanus. (*Note to the twelfth edition.*)

naturalized in the West Indies, and cultivated in various parts of the world, in few countries more largely than in the United States. New Jersey, Virginia, North Carolina, and the States upon the right bank of the Ohio, especially Illinois, are the sections in which it is most abundant. It has also been introduced into California. The flowers appear in July, and the seeds ripen successively in August and September. A decoction of the leaves is said to be employed effectively in the Cape Verde Islands, as a local application to the breast, for promoting the secretion of milk; and an infusion of the leaves has been given internally by Dr. Routh, with great supposed success, for producing the same effect in lying-in women with deficiency of milk. (*London Lancet*, Dec. 24, 1859.) The officinal part is the fixed oil extracted from the seeds.

1. The Seeds. These are about as large as a small bean, oval, compressed, obtuse at the extremities, very smooth and shining, and of a grayish or ash colour, marbled with reddish-brown spots and veins. At one end of the seed is a small yellowish tubercle, from which an obscure longitudinal ridge proceeds to the opposite extremity, dividing the side upon which it is situated into two flattish surfaces. In its general appearance the seed is thought to resemble the insect called the *tick*, the Latin name of which has been adopted as the generic title of the plant. Its variegated colour depends upon a very thin pellicle, closely investing a hard, brittle, blackish, tasteless, easily separable shell, within which is the kernel, highly oleaginous, of a white colour, and a sweetish taste, succeeded by a slight degree of acrimony. The seeds easily become rancid, and are then unfit for the extraction of the oil, which is acrid and irritating. In 100 parts Geiger found, exclusive of moisture, 23·82 parts of envelope, and 69·09 of kernel. These 69·09 parts contained 46·19 of fixed oil, 2·40 of gum, 20·00 of starch and lignin, and 0·50 of albumen. Mr. Henry Bower could find no starch, but separated from the seeds an albuminoid principle, which acted with amygdalin and water like emulsin, producing the odour of oil of bitter almonds, though in a less degree. (*Am. Journ. of Pharm.*, xxvi. 208.) It is highly probable that it is this principle which, acting as a ferment on the oily matter of the seeds, gives rise to changes in its nature which render them rancid. More recently, Mr. G. J. Scattergood found the odour of castor oil to be developed in the beans when bruised with water, and much more powerfully in those long kept than in the fresh. The water distilled from the seeds has a peculiar nauseous odour, quite distinct from that of the oil. (*Ibid.*, xxviii. 207.)*

Taken internally the seeds are powerfully cathartic, and often emetic. Two or three are sufficient to purge, and seven or eight act with great violence. This property depends upon an acrid principle, which has by some been thought to exist exclusively in the integuments, by others in the embryo. But it is now satisfactorily ascertained that the integuments are inert; and Guibourt maintains that the principle alluded to pervades the whole kernel, in connection with

* *Ricinia or Ricinin.* Professor Tuson has recently announced the discovery in the seeds of a peculiar alkaloid, which he proposes to name *ricinine*, but which should be called *ricinia*. To obtain it, the crushed seeds are exhausted by successive portions of boiling water; the decoction is filtered through wet muslin; the filtered liquid is evaporated to dryness over a water-bath; the extract thus obtained is exhausted by boiling alcohol; the alcoholic solution is allowed to cool, then filtered to separate a little resinous matter, and lastly concentrated and permitted to stand. In the course of some hours, a mass of nearly white crystals is deposited, which when recrystallized from alcohol, and decolorized by animal charcoal, are the alkaloid in a pure state. Ricinine crystallizes in rectangular prisms and tables, has a feebly bitter taste, somewhat resembling that of bitter almonds, is fusible and crystallizes on cooling, volatilizable unchanged, inflammable, soluble most readily in water and alcohol, and very slightly in ether or benzole. Heated with hydrate of potassa it evolves ammonia, and therefore contains nitrogen. It appears to combine with sulphuric, nitric, and muriatic acids. But a more accurate investigation is needed, before it can be admitted to be undoubtedly a distinct and pure alkaloid. A minute quantity is said to be obtained from castor oil by shaking it with water, evaporating the liquid, treating the residue with boiling benzole, and allowing the solution to evaporate spontaneously. Professor Tuson does not claim for the new alkaloid the possession of purgative properties. Two grains given to a rabbit produced no observable effect. (*Note to the twelfth edition.*)

the oil. This principle is considered by some as volatile, and is said to be dissipated by the heat of boiling water. This view is strengthened by the experiments of Mr. Scattergood above referred to; as the water distilled from the seeds proved decidedly purgative in the dose of half a fluidounce, and in twice the quantity both purged and vomited. The same experimenter found that the residue, after the seeds had been exhausted by ether and alcohol, was inert in the dose of 28 grains; and the ethereal extract proved a mild cathartic in the dose of from two to five fluidrachms. After expression of the oil, and treatment with pure alcohol, M. Calloud found the residue to be powerfully emetic in the quantity of 30 grains, taken in two doses. (*Journ. de Pharm.*, 3e sér., xiv. 190.) M. Parola states that ether also is incapable of extracting the acrid emetic principle from the seeds. At a temperature much above 212° the oil itself becomes altered, and acquires acrid properties.

2. The Oil. This may be extracted from the seeds in three ways; 1. by decoction, 2. by expression, and 3. by the agency of alcohol or other solvent.

The process by decoction, which has been practised in the East and West Indies, consists in bruising the seeds, previously deprived of their husk, and then boiling them in water. The oil, rising to the surface, is skimmed or strained off, and afterwards again boiled with a small quantity of water to dissipate the acrid principle. To increase the product it is said that the seeds are sometimes roasted. The oil is thus rendered brownish and acrid; and the same result takes place in the second boiling, if care is not taken to suspend the process soon after the water has been evaporated. Hence it happens that the West India oil has generally a brownish colour, an acrid taste, and irritating properties.

The oil is obtained in this country by expression. The following, as we have been informed, are the outlines of the process usually employed by those who prepare it on a large scale. The seeds, having been thoroughly cleansed from the dust and fragments of the capsules with which they are mixed, are conveyed into a shallow iron reservoir, where they are submitted to a gentle heat insufficient to scorch or decompose them, and not greater than can be readily borne by the hand. The object of this step is to render the oil sufficiently liquid for easy expression. The seeds are then introduced into a powerful screw press. A whitish oily liquid is thus obtained, which is transferred to clean iron boilers, supplied with a considerable quantity of water. The mixture is boiled for some time, and, the impurities being skimmed off as they rise to the surface, a clear oil is at length left upon the top of the water, the mucilage and starch having been dissolved by this liquid, and the albumen coagulated by the heat. The latter ingredient forms a whitish layer between the oil and the water. The clear oil is now carefully removed; and the process is completed by boiling with a minute proportion of water, and continuing the application of heat till aqueous vapour ceases to rise, and till a small portion of the liquid, taken out in a vial, continues perfectly transparent when it cools. The effect of this last operation is to clarify the oil, and to render it less irritating by driving off the acrid volatile matter. But much care is requisite not to push the heat too far; as the oil then acquires a brownish hue, and an acrid peppery taste. After the completion of the process, the oil is put into barrels, and sent into the market. There is reason, however, to believe that much of the American oil is prepared by merely allowing it to stand for some time after expression, and then drawing off the supernatant liquid. One bushel of good seeds yields five or six quarts, or about 25 per cent. of the best oil. If not carefully prepared, it is apt to deposit a sediment upon standing; and the apothecary may find it necessary to filter it through coarse paper before dispensing it. Perhaps this may be owing to the plan just alluded to of purifying the oil by rest and decantation. We have been told that the oil in barrels occasionally deposits in cold weather a copious whitish sediment, which it redissolves when the temperature rises. A large proportion of the drug consumed in the eastern section of the Union has been derived, by way of New Orleans, from Illinois and the neighbouring States, where it has been at times so abundant that it has been used for burning in lamps, and

for lubricating machinery.* We were informed, however, that in the year 1857, from a failure of the crops, and the consequent high price of the oil, considerable quantities were brought from the East Indies; and, in a report made to the American Pharmaceutical Association, in the autumn of 1859, it is stated that, after the first of January of that year, 20,000 gallons of castor oil, and 50,000 bushels of castor beans had been imported from the same source at the port of Boston.†

The process for obtaining castor oil by means of alcohol has been practised in France; but the product is said to become rancid more speedily than that procured in the ordinary mode. Such a preparation has been employed in Italy, and is asserted to be less disagreeable to the taste, and more effective, than the common oil obtained by expression. According to M. Parola, an ethero-alcoholic extract, and an ethereal or alcoholic tincture of the seeds, operate in much smaller doses than the oil, and with less disposition to irritate the bowels or to cause vomiting. (See *Am. Journ. of Med. Sci.*, N. S., xiii. 143.)

Properties. Pure castor oil is a thick, viscid, colourless liquid, with little or no odour, and a mild though somewhat nauseous taste, followed by a slight sense of acrimony. As found in the shops it is often tinged with yellow, and has an unpleasant smell; and parcels are sometimes though rarely met with, of a brownish colour, and hot acrid taste. It does not readily congeal by cold. When exposed to the air it slowly thickens, without becoming opaque. It is heavier than most of the other fixed oils; its sp. gr. having been stated to be 0·969 at 55° F. It differs also from other fixed oils in being soluble in all proportions in cold absolute alcohol. Weaker alcohol, of the sp. gr. 0·8425, takes up about three fifths of its weight. It has been supposed that adulterations with other fixed oils might thus be detected, as the latter are much less soluble in that fluid; but Pereira has shown that castor oil has the property of rendering a portion of other fixed oils soluble in alcohol; so that the test cannot be relied on. (*Pharm. Journ.*, ix. 498.) Such adulterations, however, are seldom practised in this country.‡ Castor oil is soluble also in ether. Its proximate composition is but

* For a particular account of the mode of cultivating the castor oil plant, and preparing the oil in the Western States, see a paper by Prof. Procter in the *Am. Journ. of Pharm* (xxvii. 99). It is stated in this paper that, by the aid of an improved press, the product of oil has been so much increased, that 15 bushels of seeds will yield 40 gallons of oil. Most of the seeds produced in Illinois are now expressed in St. Louis. (*Note to the eleventh edition.*)

† *Italian Castor Oil.* The castor oil plant is cultivated throughout Italy, but especially in the neighbourhood of Verona, where the oil is prepared with great care, and is remarkably free from the peculiar odour and taste which render this medicine so repulsive to many palates. As it is highly desirable, for certain purposes, that the oil should be as free from these properties as possible, though as a mere purgative perhaps less powerful when deprived of them, it is a point worthy of investigation why it is that the Italian oil is superior to most if not all other commercial varieties of the oil in these respects. The following facts in relation to the mode of preparing the oil practised at Verona, published by Mr. H. Groves, of Florence, acquire on this account a special value. One point of importance is that the seeds are used fresh, as the oil rapidly becomes rancid in them when kept. Another fact is that the seeds are entirely deprived of their coating before being submitted to pressure. This is effected by passing them between two revolving wooden rollers, with a winnowing machine beneath; and, to secure the complete absence of integument, they are afterwards assorted by the hand; all being rejected which are not perfectly decorticated. They are then put into hempen bags, which are arranged in layers, with a sheet of iron heated to 90° F. between them, so as to enable the oil to flow. Lastly, they are submitted to pressure in hydraulic presses. The oil which now flows is of the finest quality. An inferior kind is obtained by pressing the marc at a somewhat higher heat. (*Pharm. Journ. and Trans.*, Oct. 1866, p. 250.)—*Note to the thirteenth edition.*

‡ *Cohesion figures as a means of testing liquids.* A new mode of testing liquids has been recently proposed by Mr. Charles Tomlinson, which is applicable to this oil, and may succeed when purely chemical methods fail. When one liquid is dropped on the surface of another, there are often curious figures produced, as the drop spreads out on the surface of the liquid upon which it falls, occasioned by the conflict between the cohesion of the drop and the forces which cause its diffusion. These the author calls *cohesion figures.* As a general rule, each liquid has its own characteristic figures, which are modified by the

imperfectly understood. When exposed to destructive distillation, it yields various gaseous products, volatile oleaginous liquids, and two peculiar substances called acrolein and œnanthole; and there is left behind a spongy elastic mass of remarkable properties. By nitrous acid the oil is solidified, and converted into a fatty substance, which was named at first *palmin*, but afterwards *ricinelaïdin*, from its analogy with the product of a similar reaction on olive oil. This principle yields *palmic* or *ricinelaïdic acid* and glycerin on saponification. The oil appears to be a glyceride; and, when it is saponified, and the soap decomposed by an acid, an oily liquid is obtained, consisting chiefly of ricinoleic acid, and a small portion of a solid acid, which is supposed to be a mixture of stearic and palmitic acids. (Gregory's *Handbook*, 4th ed., p. 303.) Its constituents would, therefore, seem to be mainly ricinolein and a little stearin and palmitin. Ricinoleic acid is converted by caustic potassa into caprylic alcohol and sebacic acid, with disengagement of hydrogen; and the same products are obtained by the reaction of potassa with the oil itself. (See *Journ. de Pharm.*, Août, 1855, p. 113.) M. Lefort gives the formula $C_{56}H_{52}O_8$, as representing the ultimate composition of castor oil. (*Ibid.*, 3e sér., xxiii. 348.) Its purgative property is supposed by MM. Bussy and Lecanu to belong essentially to the oil, and not to any distinct principle which it may hold in solution.

Castor oil which is acrid to the taste may sometimes be rendered mild by boiling it with a small proportion of water. If turbid, it should be clarified by filtration through coarse paper. On exposure to the air, it is apt to become rancid, and is then unfit for use.*

Medical Properties and Uses. Good castor oil is a mild and speedy cathartic, usually operating with little griping or uneasiness, and evacuating the contents of the bowels without much increasing the alvine secretions. Hence, it is particularly applicable to constipation from collections of indurated feces, and to cases in which acrid substances have been swallowed, or acrid secretions have accumulated in the bowels. From its mildness it is also especially adapted to diseases attended with irritation or inflammation of the bowels; as colic, diarrhœa, dysentery, and enteritis. It is habitually resorted to in cases of pregnant and puerperal women, and is decidedly, as a general rule, the best and safest cathartic for children. Infants usually require a larger relative dose than adults, probably because they digest more of the oil.

The dose for an adult is about a fluidounce, for an infant from one to three or four fluidrachms. It is sometimes difficult of administration, not so much from any peculiarly disagreeable taste, as from the recollection of former nausea, or other uneasiness which it may have produced, and from its clamminess and adhesiveness to the mouth. In a few cases, the disgust which it excites is utterly unconquerable by any effort of resolution. It is desirable, therefore, to obviate this inconvenience, as far as possible, by the mode of exhibition. A common method is to give it floating in mint or cinnamon water; but that which we have found upon the whole the least offensive, is to mix it with a cup of hot

admixture of other liquids, and thus the means are afforded of testing not only the identity of any suspected liquid, but also its purity. To one not acquainted with the characteristic cohesion figures, it would be sufficient to try the experiment with a specimen known to be pure, and then to compare with the figure it forms, those formed by the specimen to be tested. The experiment should always be made under precisely similar circumstances. In reference to castor oil, it should be dropped from the end of a glass rod upon the surface of perfectly clear water, in a glass vessel scrupulously clean; as any imperfection in these respects might interpose a physical impediment to the success of the experiment. (*Chem. News*, Feb. 13, 1864, p. 79. See also *Am. Journ. of Pharm.*, July, 1864.)

Effect on light. Another test for castor oil is its influence on polarized light. The fixed oils generally have little or no power. Castor oil deviates the plane of polarization to the right, but loses this property if heated to 270° C. (*Journ. de Pharm.*, Nov. 1861, p. 339.) —*Note to the twelfth edition.*

* The following method of purifying rancid castor oil is recommended by M. Pavesi. Mix 1000 parts of the oil with 25 parts of purified bone-black and 10 of magnesia; allow the mixture to stand for three days, with occasional agitation; then filter through paper or felt. (*Repert. de Pharm.*, Sept. 1857.)—*Note to the twelfth edition.*

sweetened coffee, by which it is rendered more fluid, and its taste considerably disguised. Some take it in wine, or spirituous liquors, or the froth of porter; but these are often contraindicated by their stimulant property. When the stomach is unusually delicate, the oil may be made into an emulsion with mucilage or the yelk of an egg, loaf sugar, and an aromatic water. Tragacanth has been recommended as producing a better emulsion than gum arabic. Laudanum may be added in cases of intestinal irritation. It has been proposed to give the oil in the air-bladders of fishes, which may be preserved in alcohol for the purpose.* Castor oil may also be beneficially used as an enema, in the quantity of two or three fluidounces, mixed with some mucilaginous liquid. It has been recommended as a local application to the breasts of nursing women, to promote the secretion of milk.

Though apt to become rancid by itself, it loses much of this susceptibility when mixed with lard; and some apothecaries are said to use it as a substitute for olive oil in unguents and cerates. But the slightly irritating properties of even the mildest castor oil render it unfit for those preparations which are intended to alleviate irritation.

OLEUM ROSÆ. *U. S.*

Oil of Roses.

The volatile oil obtained from the petals of Rosa centifolia. *U. S*

See ROSA CENTIFOLIA.

This is commonly called *attar, otto,* or *essence of roses.* It is prepared on a large scale in Turkey in Europe, especially in the Balkan mountains, in Egypt, Persia, Cashmere, India, and other countries of the East; but commerce is at present supplied chiefly from the region constituting the southern slope of the Balkans. In the south of France it is prepared in small quantities by distilling the petals of the rose with water. The oil concretes and floats upon the surface of the water when it cools. The precise species of rose from which the oil is extracted is not in all instances certainly known; but it is said to be obtained from *R. damascena* in Northern India, *R. moschata* in Persia, and *R. centifolia (provincialis)* in the north of European Turkey. It is furnished in very minute proportion; not more than three drachms having been obtained by Colonel Polier, in Hindostan, from 100 lbs. of the petals. It is usually imported in small bottles, and is very costly.†

Oil of roses is said to be prepared in Macedonia by crushing the petals in mills, expressing the fluid part, filtering it, and then exposing it to the sun in small glass vessels. The oil gradually collects on the surface of the liquid, and is removed. (*Pharm. Cent. Blatt,* 1847, p. 783.)

Landerer states that, at Damascus and other parts of Asia Minor, the oil is prepared by dry distillation. The buds being collected before sunrise are placed in a glass retort; and the distillation is effected by a salt-water bath, care being taken so to regulate the heat as not to scorch the petals. The water of the fresh roses and their oil come over together, and the latter, floating on the top, is separated in the usual mode.

Oil of roses is nearly colourless, or presents some shade of green, yellow, or red; but, according to Polier, the colour is no criterion of its value. It is concrete below 80°, and becomes liquid between 84° and 86°. Its odour is very powerful and diffusive. At 90° its sp. gr. is 0·832. Alcohol dissolves it, though

* Oil of bitter almonds has been proposed as an effectual means of destroying the taste of castor oil. It is to be employed in the same method as in the case of cod-liver oil. (See *page* 603.) Another measure is to beat the oil well with the contents of an egg, adding a little salt, sugar, and a few drops of orange flower water. (*Note to the twelfth edition.*)

† See a paper by Prof. J. L. Smith, on the preparation of the otto of rose in the Balkans, in the *Am. Journ. of Pharm.,* July, 1859, p. 324.

not freely when cold. It consists of two oils, one liquid, the other concrete at ordinary temperatures. These may be separated by freezing the oil, and compressing it between folds of blotting paper, which absorbs the liquid oil, and leaves the concrete or stearoptene. The latter consists exclusively of carbon and hydrogen; the former, of these with oxygen. It is said that the odour resides exclusively in the liquid oil, the pure stearoptene being scentless.

Sandal-wood oil, other volatile oils, fixed oils, spermaceti, &c., are said to be added as adulterations. The volatile additions may be detected by not being concrete; the fixed, by the greasy stain they leave on paper when heated. Guibourt has offered certain tests by which he thinks the purity of the oil may be determined. (See *Am. Journ. of Pharm.*, xxi. 318.) It is said that the oil of one of the sweet-scented Pelargoniums, perhaps the *rose-geranium*, is much employed in Turkey for the purpose of adulteration; but this is probably a mistake. According to Mr. Hanbury, who appears to have thoroughly investigated the subject, two substances especially are used in Constantinople for adulterating the oil; one spermaceti, the other a volatile oil, produced by certain grasses in the East Indies belonging to the genus *Andropogon*, large quantities of which are exported from Bombay, partly directly to Europe, partly through the Arabian Gulf, whence it reaches Constantinople. The same oil is imported into London under the name of *Turkish essence of geranium*. (*Pharm. Journ.*, April, 1859, p. 506.)*

A test of the genuineness of oil of roses has been proposed by Hager, consisting in the action of strong sulphuric acid, which, added in the quantity of twenty drops to five drops of the oil, produces a reddish-brown mixture, which, if shaken when cold with three drachms of absolute alcohol, will, if the oil be pure, change into a tolerably clear yellowish-brown solution, remaining clear if heated to ebullition; whereas, if the oil be adulterated, the mixture will continue very cloudy, and sometimes a deposit will form. Professor Redwood, however, on trying the test, did not find it satisfactory. (*Pharm. Journ. and Trans.*, Feb. 1866, p. 424, and April, 1866, p. 499.)

Oil of roses may be added, as a grateful perfume, to various spirituous preparations for internal use, and to cerates and ointments. W.

OLEUM SUCCINI. *U. S.*

Oil of Amber.

The volatile oil obtained by the destructive distillation of Amber. *U. S.*

Amber. *Succinum.* This is a fossil resin, derived, probably, from extinct coniferæ, occurring generally in small detached masses, in alluvial deposits, in different parts of the world. It is found chiefly in Prussia, either on the seashore, where it is thrown up by the Baltic, or underneath the surface, in the alluvial formations along the coast. It is said that the whole annual product of the Baltic coast is at present about 200,000 pounds. (*Am. Journ. of Pharm.*, July, 1868, p. 369.) Large deposits occur in some lakes on the eastern coast of Courland, and an extensive bed of yellow amber was discovered in 1854, on sinking a well in the coal mines near Prague. The largest mass of amber, yet found, weighed thirteen pounds. Amber also occurs in considerable quantities near Catania, in Sicily. It is usually associated with lignite, and sometimes encloses

* For a paper by Dr. R. Bauer, of Constantinople, giving an account of oil of roses in all its relations, its production, properties, adulteration, &c., the reader is referred to the *Pharm. Journ. and Trans.* (Dec. 1867, p. 286).—*Note to the thirteenth edition.*

insects and parts of vegetables. In the United States, it was found at Cape Sable, Maryland, by Dr. Troost. In this locality it is associated with lignite and iron pyrites. It has also been discovered in New Jersey. The amber, consumed in this country, is brought from the ports of the Baltic. A mine of it is said to have been discovered, and is now worked, near Rokwood in Australia

It is a brittle solid, generally in small irregular masses, permanent in the air, having a homogeneous texture and vitreous fracture, and susceptible of a fine polish. It becomes negatively electric by friction. Its colour is generally brownish-yellow, either light or deep; but is occasionally reddish-brown or even deep-brown. It has no taste, and is inodorous when cold, but exhales a peculiar, aromatic smell when heated. It is usually translucent, though occasionally transparent or opaque. Its sp. gr. is about 1·07. Water and alcohol scarcely act on it. When heated in the open air, it softens, melts at 548°, swells, and at last inflames, leaving, after combustion, a small portion of ashes. Subjected to distillation in a retort furnished with a tubulated receiver, it yields, first, a yellow acid liquor; and afterwards a thin yellowish oil, with a yellow waxy substance, which is deposited in the neck of the retort and the upper part of the receiver. This waxy substance, exhausted by cold ether of the part soluble in that menstruum, is reduced to a yellow micaceous substance, identical with the *chrysen* of Laurent. A white crystalline substance, identical with the *idrialin* of Dumas, may be separated from the micaceous substance by boiling alcohol. Both chrysen and idrialin are carbohydrogens. (Pelletier and Walter, *Journ. de Pharm.*, v. 60.) As the distillation proceeds, a considerable quantity of combustible gas is given off, which must be allowed to escape. By continuing the heat, the oil gradually deepens in colour, until, towards the end of the distillation, it becomes black and of the consistence of pitch. The oil obtained is called *oil of amber*, and the acid liquor is a solution of impure *succinic acid*. Repeatedly distilled from nitric acid, amber yields an acid liquor, from which, after it has been neutralized with caustic potassa, ether separates pure camphor (Doepping, *Journ. de Pharm.*, vi. 168) Camphor is also obtained by distilling to dryness powdered amber with an extremely concentrated solution of caustic potassa. (G. Reich, *Ibid.*, xiii. 33.)

According to Berzelius, amber consists of 1. a volatile oil of an agreeable odour in small quantity; 2. a yellow resin, intimately united with a volatile oil, very soluble in alcohol, ether, and the alkalies, easily fusible, and resembling ordinary resins; 3. another resin, also combined with a volatile oil, soluble in ether and the alkalies, sparingly soluble in cold, but more soluble in boiling alcohol; 4. succinic acid; 5. a bituminous principle insoluble in alcohol, ether, and the alkalies, having some analogy to the lac resin of John, and constituting more than four-fifths of the amber. It also contains a strongly odorous, bright-yellow substance, which hardens by time, but preserves in part its odour. The ultimate constituents of amber are carbon 80·59, hydrogen 7·31, oxygen 6·73, ashes (silica, lime, and alumina) 3·27 = 97·90. A minute proportion of sulphur has also been found among its constituents. (*Journ. de Pharm.*, Mai, 1864, p. 404.)

Amber was held in high estimation by the ancients as a medicine; but at present is employed only in pharmacy and the arts. In pharmacy it is used to prepare oil of amber and succinic acid. In the arts it is made into ornaments, and employed in preparing varnishes. When put to the latter use it requires to be first subjected to roasting, whereby it is rendered soluble in a mixture of linseed oil and oil of turpentine. This solution forms *amber varnish*. B.

Oil of Amber. *Oleum Succini. Crude Oil of Amber.* In the U. S. Pharmacopœia of 1850, this is placed among the Preparations; in the existing edition, it has been transferred to the Materia Medica list. The following are the former officinal directions for its preparation.

"Take of Amber, in powder, *any quantity*. Put the Amber, previously mixed with an equal weight of sand, into a glass retort, which is to be only half filled; then distil, by means of a sand-bath, with a gradually increasing heat, an acid liquor, an oil, and a concrete acid impregnated with oil. Separate the oil from the other matters, and keep it in well-stopped bottles." *U. S.*

The amber in this process undergoes decomposition, and affords, among other products, an empyreumatic oil, which floats in the receiver upon the surface of an acid liquor. The heat requisite for the complete decomposition of the amber cannot be supported by a glass retort; and, in order that all the oil which it is capable of yielding may be collected, the distillation should be performed in a tubulated iron or earthenware retort, which may be placed immediately upon the fire. The sand is added to prevent the amber from swelling too much. The oil may be separated from the acid liquor by means of the separating funnel. As first procured, it is a thick, very dark-coloured liquid, of a peculiar strong empyreumatic odour. In this state it is occasionally employed as a liniment; but for internal use it should be rectified. It is said that the scrapings of *copal* and the resin *dammar* are often substituted for amber, and yield an oil scarcely distinguishable from the genuine. (*Pereira.*)

OLEUM TEREBINTHINÆ. *U. S., Br.*

Oil of Turpentine.

The volatile oil distilled from the turpentine of Pinus palustris and of other species of Pinus. *U. S.* The oil distilled from the oleo-resin (turpentine) obtained from Pinus palustris, Pinus Tæda, and sometimes Pinus Pinaster. *Br.*

Huile volatile de térébenthine, *Fr.;* Terpenthinöl, *Germ.;* Olio della tremer tina, *Ital.;* Aceyte de trementina, *Span.*

See TEREBINTHINA.

This oil is commonly called *spirits* or *spirit of turpentine.* It is prepared by distillation from our common turpentine, though equally afforded by other varieties. It may be distilled either with or without water; but in the latter case a much higher temperature is required, and the product is liable to be empyreumatic. To obtain it quite pure it should be redistilled from a solution of caustic potassa. The turpentine of *Pinus palustris* is said to yield about 17 per cent. of oil; while the common turpentine of Europe affords 24 per cent. Large quantities are distilled in North Carolina for exportation.

Pure oil of turpentine is perfectly limpid and colourless, of a strong, penetrating, peculiar odour, and a hot, pungent, bitterish taste. It is much lighter than water, having the sp. gr. 0·86 at 72° F.; is highly volatile and inflammable; boils at a temperature somewhat higher than 300°; is very slightly soluble in water, less soluble in alcohol than most other volatile oils, and readily soluble in ether. Boiling alcohol dissolves it with facility, but deposits most of the oil upon cooling. One hundred parts of alcohol of 0·84 dissolve 13·5 parts of the oil at 72°. As found in commerce, it always contains oxygen; but, when perfectly pure, it consists exclusively of carbon and hydrogen, and is thought to be isomeric with the radical of camphor. Hence it has been denominated camphene. (See *page* 203.) According to Blanchet and Sell, it consists of two distinct isomeric oils, which, by the absorption of oxygen, are converted into two distinct resins, corresponding to those found by Unverdorben in colophony. (*Journ. de Pharm.*, xx. 226.) But there is reason to believe that these oils are the results of chemical reaction; as, when isolated, they have boiling points higher than that of the original oil. Heated in close vessels to 482° F., oil of turpentine undergoes certain changes in properties, without any discoverable change of composition. (*Ibid.*, 3e sér., xxiv. 428.) It absorbs muriatic acid, forming with it two compounds, one a red dense liquid, the other a white crystalline substance resembling camphor, and hence called *artificial camphor.* The latter consists of the unaltered oil (camphene) combined with the acid, and is therefore muriate of camphene. In the former the oil appears to have undergone some molecular change, being converted into an oil isomeric with the oil of turpentine, but differing from it in its action on polarized light, and in forming a liquid compound with muriatic acid. Nitric acid converts oil of turpentine into resin, and by long boiling into *turpentinic acid.* Mixed with water and chlo-

ride of lime, and then distilled, the oil yields a liquid which M. Chautard found to be identical with chloroform. (*Ibid.*, 3e sér., xxi. 88.) On exposure to air and light, it deposits white acicular crystals, which are without taste or smell, insoluble in cold water, but soluble in ether and alcohol. (Boissenot, *Journ. de Chim. Méd.*, ii. 143.) White crystals of stearoptene, heavier than water and fusible at 20°, separate from the oil at the temperature of 18° below zero. These are probably a hydrate of the oil. The hydrate may be produced by exposing on a plate four volumes of the oil recently distilled, three of alcohol, and one of nitric acid. Crystals form at the end of a week or more. This happens though the oil may be mixed with others, and may serve to detect adulterations with it of oils which do not have the same composition. (Berthelot, *Journ. de Pharm. et de Chim.*, xxviii. 451.) The name of *terpin* has been given to this crystalline hydrated oil of turpentine; and similar crystals, if not identically the same in character, have been taken from the interior of an old pine log, where they were probably formed from the oil remaining in the structure of the wood (John M. Blake, *Am. Journ. of Sciences and Arts*, A. D. 1867, xliii. 202.)

Exposed to the air the oil absorbs oxygen, becomes thicker and yellowish, and loses much of its activity, owing to the formation of resin. A small proportion of formic acid is said also to be generated. Hence the Edinburgh College directed the oil to be rectified by distilling it with about four measures of water. But the process is difficult in consequence of the great inflammability of the vapour, and its rapid formation, which causes the liquid to boil over. In this country it is scarcely necessary; as the recent oil can be obtained at an expense less than that which would be incurred by redistillation on a small scale. Another mode of purifying the oil is to agitate it with one-eighth of alcohol, which dissolves the resinous portion. About one-fifth of the alcohol is retained by the oil, but is readily separated by agitation with water.

The oil as obtained from different species of pine or fir, though having many common properties, and identical in composition, is somewhat different, especially in relation to its influence on polarized light. Thus, the oil used in this country, derived from Pinus palustris, produces deviation of the plane of polarization to the right, while the French oil, from Pinus maritima, has the contrary effect. M. Berthelot, after numerous experiments, has come to the conclusion, that the oils of turpentine of the formula $C_{20}H_{16}$, whether from the same or different trees, are mixtures of several isomeric carburets, constituting permanent varieties, which carry their distinctive character with them into combination, as in their artificial camphors and hydrates, which have the same rotary power as their respective oils. (*Journ. de Pharm. et de Chim.*, xxv. 263.)

Berthelot has shown that oil of turpentine has, under certain conditions, the power, while undergoing oxidation itself, of causing the oxidation of other bodies, to which it imparts a portion of the oxygen absorbed from the air. All that is necessary to give this power to the oil is that, soon after distillation, it should be exposed to the air, as in a bottle half filled. Solar light assists, but is not essential to the change, which goes on even in the dark. The oil retains the property thus acquired indefinitely, but may be deprived of it by exposure to a boiling heat, or by agitation with certain other substances, as pyrogallate of potassa. No other chemical or physical change can be detected in the oil. (*Journ. de Pharm.*, Mai, 1860, p. 351.)

In this country the oil of turpentine, though often more or less impure from the presence of resin, is probably not often adulterated. An instance, however, has been put on record, in which a sample of the oil, having a pale-green colour, was found to contain copper. This was easily separated by shaking the oil with a little saturated solution of prussiate of potassa, and allowing it to stand for two or three days to settle. (C. Lewis Diehl, *Am. Journ. of Pharm.*, Sept. 1867, p. 386.)

Medical Properties and Uses. Oil of turpentine is stimulant, diuretic, occasionally diaphoretic, anthelmintic, in large doses cathartic, and externally rubefacient. Swallowed in moderate quantities it produces a sense of warmth in the

stomach, accelerates the circulation, and increases the heat of the skin, without especially affecting the functions of the brain. In small doses, frequently repeated, it stimulates the kidneys, augmenting the secretion of urine, and often producing, especially if long continued, painful irritation of the urinary passages, amounting sometimes to violent strangury. At the same time it imparts the odour of violets to the urine; and this effect is also produced by its external application, or even by breathing the air of an apartment impregnated with its vapours. In large doses it occasions slight vertigo, or a sense of fulness in the head, sometimes amounting to intoxication, attended frequently with nausea, and succeeded generally, though not always, by speedy and brisk catharsis. When this effect is experienced, the oil is carried out of the bowels, and, no time being allowed for absorption, is less apt to irritate the kidneys and bladder than in small and repeated doses. In some constitutions it produces, even when taken internally, an erythematic eruption on the skin. Persons who inhale its vapour are liable to strangury and even bloody urine. We have seen cases of hæmaturia in seamen from on board vessels loaded with turpentine. A case is on record in which a woman was found dead, after having swallowed a large quantity of the oil, probably about six ounces. The muscles were in a state of rigid contraction; the membranes of the brain and spinal marrow were greatly congested, and the brain in a less degree; and the lungs and right cavities of the heart were gorged with blood. The inference is that death resulted from asphyxia, produced probably by a tetanic contraction of the muscles of respiration. (See *Am. Journ. of Med. Sci.*, Oct. 1858, p. 562.)

The oil is employed in numerous diseases. As a stimulant it sometimes proves serviceable in low forms of fever. We have found it extremely useful in the advanced stage of typhoid or enteric fever; and especially in cases in which the tongue has partially or completely thrown off its fur in flakes, and afterwards become dry, with a surface destitute of its ordinary papillary appearance, and often contracted and fissured. The remedy has, in our hands, proved almost uniformly successful under these circumstances. With small doses of the oil frequently repeated, the tongue becomes moist and again coated, the tympanitic state of the bowels disappears, and the patient goes on to recover as in a favourable case of fever. Its efficiency, however, in typhoid fever, is ascribable not so much to its stimulant properties, as to an alterative influence upon the ulcerated surface of the bowels characteristic of that disease. The medicine has been recommended as a counter-irritant in yellow and puerperal fevers; and may undoubtedly be given with advantage in the latter stages of these diseases, and in other instances of gastric and enteric inflammations, which require a resort to stimulation. In chronic rheumatism, particularly sciatica and lumbago, the oil has often been given with great benefit. It has also been much extolled as a remedy in neuralgia, in epilepsy and tetanus, in passive hemorrhages, particularly from the bowels, in disordered conditions of the alimentary canal attended with sallow countenance, foul tongue, tumid abdomen, sour or fetid eructations, and general depravation of health, in obstructions of the bowels, in chronic dysentery and diarrhœa, in obstinate gleets and leucorrhœa, in suppression of urine, and retention and incontinence of urine from debility, and in chronic nephritic and calculous affections. In certain cases of dysentery, whether acute or chronic, when the tongue is quite dry, and smooth as if from defect of the papillary structure, no remedy has proved so efficient in our hands as oil of turpentine. We have seen it also very beneficial in hæmoptysis. As a vermifuge it is highly esteemed, especially in cases of tænia. It appears to destroy or debilitate the worm, which, losing its hold upon the bowels, is then easily discharged. In cases of worms in the stomach it is very useful. The worms, in this instance, are destroyed, and then digested as any other dead animal matter. In dropsies with feeble action the oil may sometimes be advantageously given as a diuretic; and in amenorrhœa from torpor of the uterine vessels it is occasionally useful. As a local stimulant it may be given beneficially in some instances of flatulent colic, and gout in the stomach.

The dose for ordinary purposes is from five to thirty drops, repeated every hour or two in acute, and three or four times a day in chronic diseases. In rheumatism it is recommended by some in the dose of a fluidrachm every four hours. As a remedy for the tape-worm it is given in the quantity of one or two fluidounces, and should be followed by castor oil if it do not operate in three or four hours. It has also proved successful in tænia in the dose of half a drachm, twice a day, continued for a considerable time. In ordinary cases of worms, the usual dose may be given. It may be administered on sugar, or in emulsion with gum arabic, loaf sugar, and cinnamon or mint-water.

In the form of enema, the oil has been employed in amenorrhœa, and to promote uterine contraction in child-birth, and is highly useful in cases of ascarides, obstinate constipation, and distension of the bowels from accumulation of air. No remedy is more effectual in tympanites than injections of oil of turpentine. From half a fluidounce to two fluidounces may be administered, suspended by the yelk of eggs in half a pint or a pint of water, or some mucilaginous fluid.

Externally applied, oil of turpentine irritates and speedily inflames the skin; and, in low forms of fever with coldness of the surface, is when heated one of the most efficacious rubefacients. It is also used as a liniment in rheumatic and paralytic affections, and various internal inflammations. It should generally, in mild cases, be diluted with olive oil; and in some constitutions, even in this state, produces such violent inflammation of the skin, with extensive eruptions, as to render its external use in any shape improper. Mixed with some mild oil, and introduced on cotton into the ear, it is sometimes beneficial in deafness arising from a deficient or unhealthy secretion of wax. Applied to recent burns, it is thought by some to be highly useful in allaying the burning pain and promoting a disposition to heal. For this purpose, however, it is usually mixed with resin cerate (*basilicon ointment*), so as to form a liniment capable of being spread upon linen rags. (See *Linimentum Terebinthinæ.*)* The oil has been recommended also in anthrax and erysipelas. M. Beullard has found it useful in eczema, applied directly to the affected part. It causes immediately severe pain and much swelling, and in a few minutes must be removed, and followed by cooling and demulcent measures. A modification of the disease is thus produced, which renders ordinary applications successful that had been previously useless. (*Ann. de Thérap.*, 1865, p. 138.)

Oil of turpentine has been recommended in the form of bath, in affections in which its constitutional impression is desired. For this purpose Dr. T. Smith, of Cheltenham, England, employs from five to ten fluidounces of the oil, with half a fluidounce of the oil of rosemary, and two pounds of carbonate of soda in each bath. The breath becomes strongly impregnated with the terebinthinate odour. (*Braithwaite's Retrospect*, xxi. 355.) Applied in vapour, the oil is said to be a very speedy cure for the itch. The bed and night clothes are sprinkled with thirteen drachms of the oil, and the patient finds himself cured on awaking in the morning. (*Am. Journ. of Med. Sci.*, July, 1857, p. 232.) Baths of the vapour of turpentine are stated to be very beneficial in chronic rheumatism. They are said to be borne well, for twenty-five minutes, at a temperature from 140° to 160° F. (*Arch. Gén.*, 4e sér., xxviii. 80) Inhalation of the vapour has been recommended by Skoda in gangrene of the lungs.

OLEUM THEOBROMÆ. *U.S., Br.*

Oil of Theobroma. Butter of Cacao. Cacao Butter.

The concrete oil of the kernels of the fruit of Theobroma Cacao. *U.S.* A concrete oil obtained by expression and heat from the ground seeds of Theobroma Cacao. *Br.*

THEOBROMA. *Sex. Syst.* Polyadelphia Decandria. — *Nat. Ord.* Sterculiaceæ. *Lindley.*

Gen. Ch. Calyx sepaled. *Petals* 5, vaulted at the base, ligulate above. *Stamens* 15, connected into an urceolus at the base; sterile filaments 5, alternate with the petals; fertile ones short, united into 5 filaments, each opposite to a petal and bearing 2 anthers. *Style* 5-cleft at the apex. *Stigmas* simple. *Fruit* indehiscent, 5-celled. *Seeds* embedded in a buttery pulp.

Theobroma Cacao. Linn. *Sp. Pl.* 1100; Hayne, *Darstel. und Beschreib. &c.*, ix. 35. This is a handsome tree, from twelve to twenty feet in height, growing in Mexico, the West Indies, and South America, in some parts of which it is largely cultivated, particularly in Guayaquil and Venezuela. The fruit is an oblong-ovate capsule or berry, six or eight inches in length, with a thick, coriaceous, somewhat ligneous rind, enclosing a whitish pulp, in which numerous seeds are embedded. These are ovate, somewhat compressed, about as large as an almond, and consist of an exterior thin shell, and a brown oily kernel. Separated from the matter in which they are enveloped, they constitute the *cocoa*, *cacao*, or *chocolate nuts* of commerce They have a slightly aromatic, bitterish, oily taste, and, when bruised or heated, an agreeable odour. Analyzed by Mitscherlich, they were found to contain, in 100 parts, from 45 to 49 of fixed oil (*cacao butter*), 14 to 18 of starch, 0·34 of glucose, 0·26 of cane sugar, 5·8 of cellulose, 3·5 to 5 of colouring matter, 13 to 18 of albuminoid matter, 1·2 to 1·5 of theobromin, 5·6 to 6·3 of water, with 3·5 ashes. The colouring matter is probably the result of chemical change, as the fresh seeds are white. Theobromin has been found also in the shells in the proportion of about 1 per cent. (See *Am. Journ. of Pharm.*, Nov. 1862, p. 509.) The shells of the nuts are sometimes employed in the state of infusion, as a substitute for tea or coffee. They impart to boiling water a taste analogous to that of chocolate, but weaker. The kernel is consumed in great quantities, in the shape of chocolate, or in some analogous form.

Theobromin (or more properly *theobromia*) was discovered by M. Woskresensky, who obtained it in the following method. The kernels are exhausted with water by means of the water-bath; the solution is strained through linen, precipitated by acetate of lead, and filtered; the filtered liquid is freed from lead by sulphuretted hydrogen, and evaporated; the brown residue is treated with boiling alcohol, and the liquid filtered while hot. Upon cooling, the theobromia is deposited in the form of a reddish-white powder, which is rendered colourless by repeated crystallization. Keller obtained it still purer by heating the powder between two watch-glasses, by which a brilliant white sublimate was obtained. (*Gmelin's Handbook.*) Theobromia is a nitrogenous crystallizable principle, capable of forming salts with the acids, very bitter, volatilizable without change, freely soluble in hot alcohol, sparingly so in hot water, and closely analogous to caffein. Its formula, according to Dr. F. Keller, is $C_{14}H_8N_4O_4$. It has been converted into caffein by Prof. Strecker. (See *Am. J. of Pharm.*, Sept. 1861, p. 406.)

Chocolate is differently prepared in different countries. In Great Britain and the United States, it usually consists, when pure, exclusively of the cocoa or chocolate nuts, which are first roasted, then deprived of their shell, and lastly reduced, by grinding between heated stones, to a paste, which is moulded into oblong cakes. Not unfrequently rice flour or other farinaceous substance, with butter or lard, is added; but these must be considered as adulterations. On the continent of Europe, sugar is generally incorporated with the paste, and spices, especially cinnamon, are often added. Vanilla is a favourite addition in South America, France, and Spain. Cocoa is often sold in the state of powder,

which is sometimes mingled with other ingredients, such as ground rice, barley flour, sugar, &c. Chocolate is prepared for use by reducing it to powder, and boiling it in milk, water, or a mixture of these fluids. In this state it is much employed as a drink at breakfast and tea, and serves as a substitute for coffee in dyspepsia. It is also a good article of diet for convalescents, and may sometimes be given advantageously as a mild nutritive drink in acute disease.

Oil of Theobroma. Cacao Butter. This is the fixed oil of the chocolate nut. It is extracted either by expression, decoction, or the action of a solvent. Soubeiran recommends that the seeds, previously ground, be mixed with one-tenth of their weight of water, then pressed between hot plates of tinned iron. It is advisable that the heat should not exceed that of boiling water, and even a lower heat will answer. When the method of decoction is used, the cacao should be slightly roasted before boiling. As a solvent, bisulphide of carbon has been found to answer well, as recommended in the preparation of the expressed oil of nutmeg. (See *Oleum Myristicæ.*) Upon the whole, the method of expression is perhaps preferable. The presence of water in the ground seeds is said greatly to facilitate the process. The expressed oil, which is generally imported, comes in the shape of oblong cakes, like those of chocolate, weighing about half a pound each. It is whitish or yellowish, of the consistence of tallow, with an agreeable odour resembling that of chocolate, and a bland, pleasant taste. It was analyzed by Specht and Gössman, who found it to consist of stearin, palmitin, and olein. From its large proportion of stearin, it is one of the best fats for the preparation of stearic acid. (*Chem. Gaz.*, Aug. 15, 1854, p. 306.) It is said to be frequently adulterated with animal fats.

Butter of cacao is used as an ingredient in cosmetic ointments, and in pharmacy for coating pills, and preparing suppositories. For the last purpose it is well adapted by its consistence and blandness, and is now largely consumed. It was, indeed, on this account chiefly that it was introduced into the present edition of the U. S. Pharmacopœia.* A good lip salve is said to be prepared by melting together 28 ounces of cacao butter, 4 ounces of yellow wax, and a drachm, each, of balsam of Peru and benzoic acid, straining, adding perfuming oils, as those of rose, bergamot, and bitter almonds, in sufficient quantity, and finally, when nearly cool, an ounce of glycerin. (F. Bringhurst, *Am. Journ of Pharm.*, July, 1867, p. 348.)

OLEUM THYMI. *U.S.*

Oil of Thyme.

The volatile oil obtained from Thymus vulgaris. *U. S.*

This was introduced into the present edition of the U. S. Pharmacopœia, under the impression, that what is usually employed under the name of *oil of origanum*, and by that name was recognised in former editions of the Pharmacopœia, is really the product of the Thymus vulgaris, or common thyme. This fact was ascertained by Mr. Daniel Hanbury, during a journey in the south of France, where thyme grows wild in great abundance, and is largely collected for distillation. The oil is taken from France to England, and thence reaches this country under the name of oil of origanum, having, probably from its

* *Mafurra Tallow.* Under this name a fatty matter is known, obtained from the fruit of a tree growing in Mozambique, and the Isles of Madagascar and Bourbon, and bearing a close resemblance in qualities to cacao butter. The kernel of the fruit is described as of the size of the cacao bean, having the same characteristic odour when bruised, and a bitter taste. The fatty matter is extracted by boiling the kernels in water. It is of a firm solid consistence, less fusible than tallow, of a yellowish colour, and the odour of cacao butter. It agrees, moreover, with that substance in containing olein and palmitin, and yields palmitic acid largely when saponified. The tree which yields it will probably be found to bear a close botanical affinity to Theobroma. (See *Am. Journ. of Pharm.*, xxviii. 163.)

greater cheapness, been substituted for the genuine oil. The substitution is of the less importance, as, for all the purposes for which oil of origanum was used, that of thyme is not less useful, while it is at least quite as agreeable.

Thymus vulgaris is a very common plant, indigenous in the south of France, and cultivated in our gardens. It is a labiate plant, belonging to the Linnæan class and order Didynamia Gymnospermia, and characterized as a genus by its subcampanulate calyx, having its throat closed with hairs, and its corolla with the upper lip flat and emarginate, and a longer lower lip. It is a low undershrub, procumbent at the base, with ovate-linear, revolute leaves, and flowers in a whorled spike. The herbaceous portion, which should be gathered when the plant is in flower, has a peculiar, strong, aromatic, agreeable odour, not lost by drying, and a pungent, aromatic, camphorous taste. Its active constituent is the volatile oil, which is obtained separate by distillation with water.

The oil, as prepared in the south of France, is, after one distillation, of a reddish-brown colour, and called the *red oil*, but when again distilled is colourless, and in this condition is distinguished as the *white oil*. It is the former that is exclusively found in our shops. According to Zeller, one pound of the fresh herb yields 45·7 grains of the oil, of the dried herb 38 grains. The oil, as found in our shops, is of a reddish-brown colour, and of an odour recalling that of thyme, but less agreeable. Its sp. gr. is stated at 0·905, but probably varies, as the oil is a complex body. Besides other ingredients, it contains a principle called *thymol*, which is concrete at ordinary temperatures, and comes over last in distillation, and which in the solid state is somewhat heavier than water.

Thymic Acid. Thymol. The thymol referred to in the above paragraph has recently attracted considerable attention, under the name of thymic acid, from its possession of antiseptic properties analogous to those of carbolic and cresylic acids and creasote, with which it is also analogous in composition. It may be obtained by submitting the oil to a prolonged refrigeration, under the influence of which it crystallizes; but in this solid state it is less convenient for use than as a liquid. It appears that there are two isomeric forms of thymic acid, one the crystalline product here referred to, the other a liquid, obtained by treating the oil of thyme with an aqueous solution of potassa or soda, which separates it from a principle called *thymene* with which it is mixed in the oil, and which is not affected by the alkalies. The thymate thus formed is decomposed by an acid, and the liberated thymic acid is purified by repeated washings, desiccation, and finally distillation. In this state it may be exposed to a very low temperature, without crystallizing, not even though some crystals of the other variety be thrown in for a nucleus. In a concentrated state it has an acrid and caustic taste; but when very much diluted, the only taste perceptible is that of thyme, and a sense of coolness in the mouth like that caused by the oil of peppermint. In the crystalline state it melts at 111° F., and boils at 446° F. When once melted, it often has the peculiarity of remaining indefinitely in the liquid state. It is only very slightly soluble in water, but is very soluble in alcohol, and more freely in proportion to the concentration of the menstruum. It is dissolved by ether and the fixed oils, and has no rotary power as regards polarized light. The alkalies unite with it to form soluble salts. Like creasote it has the property of combining with animal tissues, and thus protecting them against putrefaction. Its composition is represented by the formula $C_{20}H_{14}O_2$; while *thymene*, with which it is associated in the oil, is a hydrocarbon, isomeric with the oil of turpentine, and having the composition $C_{20}H_{16}$. The disagreeable odour of carbolic or phenylic acid induced M. Bouilhon, a French pharmaceutist, to search among the analogous chemical products, in the hope of finding some one which might have the important practical properties of carbolic acid without disagreeable smell. This he believes that he has found in thymic acid. Dr. Paquet, clinical professor of surgery at Lille, has satisfied himself by numerous experiments that thymic acid has excellent antiseptic properties, which adapt it to all those purposes to which carbolic acid has been applied as a disinfectant. In a concentrated state it has,

moreover, caustic properties, which render it very useful for the cauterization of the dental nerves. Dissolved in water in the proportion of one to 1000, with the addition of a little alcohol, it is useful in the dressing of unhealthy wounds, and is peculiarly indicated in cases in which the tincture of iodine and other antiseptic remedies have proved unavailing. Combined, in the proportion of 4 parts of the acid with 4 of tannin, 2 of anilin, and 100 of glycerin, it has been used with great success by Dr. Paquet for the preservation of anatomical specimens. For the dressing of wounds, it may be used in the form of a lotion composed of 1 part of the acid, 4 of alcohol of 85°, and 995 of distilled water. In the form of ointment, it may be employed incorporated with lard in the proportion of from 2 to 20 drops to an ounce. If taken internally, it may either be formed into an emulsion, or dissolved in alcohol, or made into pills with 2 parts of the acid and 4 parts of medicinal soap, and any desirable excipient; the soap being necessary for the proper division of the acid. (*Journ. de Pharm. et de Chim.*, Août, 1868, p. 147.)

Thyme has the aromatic properties of sage, lavender, &c., and may be used for the same purposes; but it is more employed in cooking than in medicine. *T. serpillum*, or the wild thyme of Europe, is analogous in properties to the garden thyme. Both are occasionally used in baths, fomentations, and cataplasms, along with other aromatic herbs.

The oil is used almost exclusively as a local application. Introduced on lint or cotton into the cavity of a carious tooth, it will sometimes allay toothache. It is often used as a mild irritant in chronic rheumatism, sprains, bruises, &c., generally in connection with spirit and camphor. It is an ingredient, under the name of oil of origanum, in *opodeldoc*, the Linimentum Saponis Camphoratum of former editions of the U. S. Pharmacopœia, which has, we think unfortunately, been discarded from the recent edition. W.

OLEUM TIGLII. *U. S.*

Croton Oil.

The oil obtained from the seeds of Croton Tiglium. *U. S.*

Off. Syn. OLEUM CROTONIS. The oil expressed from the seeds of Croton Tiglium. *Br.*

Huile de Croton, *Fr.;* Crotonöl, *Germ.;* Nervalum unnay, *Tamool.*

CROTON. See CASCARILLA.

Croton Tiglium. Willd. *Sp. Plant.* iv. 543; Woodv. *Med. Bot.*, 3d ed., vol. v. p. 71. This species of Croton is a small tree or shrub, with a few spreading branches, bearing alternate petiolate leaves, which are ovate, acuminate, serrate, smooth, of a dark-green colour on the upper surface, paler beneath, and furnished with two glands at the base. The flowers are in erect terminal racemes, scarcely as long as the leaf; the lower being female, the upper male, with straw-coloured petals. The fruit is a smooth capsule, about the size of a filbert, with three cells, each containing a single seed.

The tree is a native of Hindostan, Ceylon, the Moluccas, and other parts of India. It is pervaded by an acrid purgative principle, probably analogous to that found in other plants belonging to the family of Euphorbiaceæ. Rumphius says that the root is employed in Amboyna, in the dose of a few grains, as a drastic purge in dropsy; and, according to the same author, the leaves are so acrid that, when chewed and swallowed, they excite inflammation in the lips, mouth, and throat, and along the whole course of the alimentary canal The wood is said in small doses to be diaphoretic, in larger, purgative and emetic. But the seeds are the most active part. These have been long used in India as a powerful purgative, and were employed so early as 1630 in Europe, under the names of *grana Molucca* and *grana tiglia.* But in consequence of their violent effects they fell into neglect, and had ceased to be ranked among medicines, when, at a comparatively recent period, attention was again called to them by the writings of some English physicians in India. They are now imported for their oil, which is the only product of the plant considered officinal.

These seeds are rather larger than a grain of coffee, oblong, rounded at the extremities, with two faces, the external considerably more convex than the internal, separated from each other by longitudinal ridges, and each divided by a similar longitudinal ridge, so that the whole seed presents an irregular quadrangular figure. Sometimes, as in the coffee grain, their internal surface is flat with a longitudinal groove, owing to the presence of only two seeds in the capsule, the groove being produced by the central column or axis. The shell is covered with a soft, yellowish-brown epidermis, beneath which the surface is black and smooth; and, as the epidermis is often partially removed by friction during their carriage, the seeds as they come to us are frequently mottled, and sometimes nearly black. The kernel or nucleus is yellowish-brown, and abounds in oil. In India the seeds are prepared for use by submitting them to slight torrefaction, by which the shell is rendered more easily separable. In the dose of one or two grains the kernel purges with great activity.

The oil is obtained by expression from the seeds, previously deprived of the shell. It may also be separated by decoction in water, or by the action of ether, or bisulphide of carbon, which dissolves the oil, and leaves it behind when evaporated.* Guibourt recommends, after the first expression, to digest the residue with alcohol at a temperature of 120° to 140° F., and then submit it to a new expression. The alcohol is to be separated by distillation from the oil, which is then to be mixed with the first product. According to Dr. Nimmo, the seeds consist of 64 per cent. of kernel, and 36 of envelope. From the seeds imported into England, about 22 per cent. of oil is obtained by simple expression. Guibourt, by his process, obtained 52 per cent. from the kernels, equivalent to about 35 from the seeds. Croton seeds yielded to Brandes upon analysis, independently of the shell, traces of a volatile oil, fixed oil, a peculiar fatty acid called *crotonic acid*, an alkaloid which he called *crotonin*, resin, stearin, wax, extractive, sugar, starch, gum, albumen, gluten, lignin, and salts. The crotonin has been subsequently found to be nothing more than a magnesian soap with an alkaline reaction. The *crotonic acid*, which is separated along with the oil on expression, has been thought to be the active principle of the seeds, but is now said to be inert. It may be obtained by treating the oil with solution of potassa, decomposing the resulting soap by tartaric acid, filtering and distilling the solution, neutralizing the product with baryta-water, evaporating to dryness, decomposing the salt of baryta with strong phosphoric acid, and again distilling. (*Christison's Dispensatory.*) The acid solidifies at 23° F., is highly volatile, has a very acrid taste, and is very irritating to the nostrils.†

Properties. Croton oil, as found in the shops, varies from a pale-yellow to a dark reddish-brown. That imported from India is usually pale, that expressed in Europe dark, like the deepest coloured sherry. Its consistence is rather viscid, and is increased by time. Its smell is faint, but peculiar, its taste hot and acrid, leaving in the mouth a disagreeable sensation which continues for many hours. The oil is wholly soluble in ether and oil of turpentine. Its re-

* *Extraction with ether.* Having washed and dried the seeds, grind them in a coffee-mill, and form a soft paste with ether. Introduce this into a narrow percolation tube, and gradually pour ether upon it until exhausted. Evaporate the ether by means of a water-bath, and filter the remaining oil through paper. (*Journ. de Pharm.*, Août, 1862, p. 116.)

Extraction with bisulphide of carbon. The seeds, well bruised, are introduced into a bottle with three times their weight of bisulphide of carbon well rectified; the mixture is allowed to stand, with frequent agitation, for 24 hours; the whole is then poured upon a cloth and rapidly expressed. The residue is similarly treated with twice its weight of the bisulphide, and expressed, after standing as before. The products of the two macerations are mixed, then filtered in a covered funnel, and finally submitted to distillation, by means of a water-bath, in a glass retort, at the temperature of 160° or 170° F. The bisulphide should be recovered by condensing its vapour in a refrigerated receiver. The oil is to be poured into a capsule, to show that it contains none of the bisulphide, and then introduced into a bottle. (*Journ. de Pharm.*, 3e ser., xxxi. 28.)—*Note to the twelfth edition.*

† Prof. Tuson believes that he has found in croton seeds a peculiar alkaloid, analogous to cascarillin. He extracts it by the same process as that already described, by which he obtained ricinin from the castor-bean. (See *note*, page 609.) But further experiments are required for satisfactory results. (See *Am. Journ. of Pharm.*, Sept. 1864, p. 418.)

lations to pure alcohol differ somewhat with the variety of the oil. That obtained by expression in England is wholly and readily soluble, forming a solution which is permanent at ordinary temperatures; while the India or pale oil forms an opaque mixture, which becomes clear and uniform upon being heated, but separates on standing into two portions, one consisting of alcohol somewhat diminished in bulk, the other of the oil correspondingly increased in bulk by retaining a portion of the alcohol. It is possible that the difference in colour, and in their relations to alcohol, between the India and English oils, may be owing to a change in the kernels from being kept.

Some croton oil examined by M. Dublanc, of Paris, when agitated with ten times its weight of alcohol, was separated into two parts, one of which amounting to 6 per cent. was dissolved by the alcohol, the other remained undissolved, but retained 50 per cent. of alcohol. The latter, upon being repeatedly treated with alcohol, lost all its acrimony; while the portion dissolved was extremely acrid. From these observations it would appear that the acrid and probably active principle of the oil is dissolved by alcohol; while a bland fixed oil, which constitutes the chief part of it, is not taken up by that liquid.*

It is thought that croton oil is often adulterated with other fixed oils. In the Br. Pharmacopœia of 1864, it was given as a test of the purity of the oil expressed from the imported seeds, that when agitated with an equal volume of alcohol and gently heated, it forms a clear solution, from which about three-fourths of the oil separate on cooling; but that statement is asserted to be untrue of the English expressed oil, though correct of the imported. The test was intended to detect the presence of castor oil, which would be dissolved by the alcohol, and thus occasion a diminution of the bulk. It has been omitted in the present Pharmacopœia.†

We were told by the late Dr. M. Burrough, who was for some time in India, that much of the oil there prepared, under the name of croton oil, is derived

* Some experiments have recently been made by Thomas Schlippe on the composition of croton oil, with very interesting results. The crotonic acid referred to in the text is only one out of a number of fatty acids contained in the oil, and is neither the acrid nor the purgative principle. Besides the proper fatty part, there are probably other ingredients upon which the medicinal activity of the oil depends. Of these Schlippe has separated the acrid, but not as yet the purgative principle. The former he calls *crotonol*.

The fatty part of the oil, when saponified, yielded *stearic*, *palmitic*, *myristic*, and *lauric acids;* and of the oleic acid series, besides some not well defined, *crotonic* and *angelic acids;* all of which exist as glycerides, that is, as compounds of the acids respectively with glycerin, in the recent oil.

Crotonol, or the acrid principle, which exists in the expressed oil in the proportion of 4 per cent., may be separated in the following manner. Agitate the oil with sufficient alcoholic solution of soda to form a milky fluid; heat this gently for some hours, and then add water or solution of chloride of sodium, so as to cause the oil to rise and form a stratum on the surface; separate this fatty oil by passing the liquid through a moist filter; to the filtrate add dilute muriatic acid, which will separate and cause to rise to the surface another oily matter; dissolve this in cold alcohol, and treat it with freshly prepared hydrated oxide of lead. When the acid reaction has quite ceased, add freely a weak watery solution of soda, by which the fluid is rendered milky, and afterwards divides into a watery liquid and a clear oil, which sinks to the bottom. To obtain this result, it is often necessary to add chloride of calcium freely to the alcoholic solution. Separate the oil, wash it with water on a moist filter, and dissolve it in ether. Agitate the ethereal solution with water in a cylindrical glass vessel, and, having drawn off the clear ethereal solution, allow the ether to evaporate in a capsule *in vacuo*. The crotonol remains as a tenacious mass, colourless or of a slightly wine colour, and of a weak and peculiar odour. Schlippe ascribes to a decomposition of the crotonol the odour, like that of decoction of seneka, which is often possessed by croton oil. (*Liebig's Annalen*, cv. 1.)—*Note to the twelfth edition.*

† Mr. Maisch proposes to detect croton oil in any mixture by the following plan, based upon Schlippe's results in reference to crotonol. The suspected oil is agitated with an alcoholic solution of soda or potassa, and the solution, having been separated, is then saturated with hydrochloric or sulphuric acid. If croton oil be present, its acrid principle, crotonol, will rise to the surface in the form of an oil, which, when applied to the skin, will produce in three or four hours not only inflammation, but also the peculiar eruptive affection excited by croton oil. (*Am. Journ. of Pharm.*, July, 1860, p. 307.)—*Note to the twelfth edition.*

from the seeds of a plant different from the Croton Tiglium. From a parcel of these seeds presented to him by Dr. Burrough, Dr. R. E. Griffith produced a plant which proved to be Jatropha Curcas, the seeds of which are known by the name of *Barbadoes nuts.* (See *Tapioca.*) This oil, though weaker than the genuine, was said by Dr. Burrough to be an efficient cathartic in the dose of three or four drops. Dr. Hamilton states that croton seeds are afforded by *Croton pavana*, growing in Ava and the eastern parts of Bengal; and it is probable that a portion of the croton oil of commerce is obtained from these seeds. (*Trans. Lin. Soc.*, xiv. 257.) These facts may explain some of the discrepancies in reference to the effects of alcohol above mentioned.

Medical Properties and Uses. Croton oil is a powerful hydragogue purgative, acting for the most part, when given in moderate doses, with ease to the patient, but in large doses apt to excite vomiting and severe griping pains, and capable, if immoderately taken, of producing fatal effects. It acts with great rapidity, frequently evacuating the bowels in less than an hour, and generally exciting a rumbling sensation in half that period. It possesses also great advantage in the minuteness of the dose, on account of which it may frequently be given when we should fail with more bulky medicines; as in mania, coma, and the cases of children. A drop placed on the tongue of a comatose patient will generally operate. Though long used in India, and known more than a century ago to the Dutch physicians, it did not attract general notice till about 1820, when it was introduced into England by Mr. Conwell. It is chiefly employed in cases of obstinate constipation, in which it often produces the happiest effects after the failure of other medicines; but it may also be advantageously used in almost all cases in which powerful and speedy purging is demanded. Dropsy, apoplexy, mania, and visceral obstructions are among the complaints in which it has been particularly recommended. It has recently been employed with great asserted benefit in neuralgia, epilepsy, and spasm of the glottis, and has been supposed to have powers in these affections independent of its purgative property. The seeds are said to have been used with great success in India in amenorrhœa. Applied externally, the oil produces inflammation of the skin, attended with a pustular eruption, and has been used in this way in rheumatism, gout, neuralgia, glandular and other indolent swellings, and in laryngeal and pulmonary diseases. It should be diluted with three parts of olive oil, soap liniment, oil of turpentine, or other convenient vehicle, and applied as a liniment twice or oftener in the twenty-four hours. Sometimes the insusceptibility of the skin is such as to require its application undiluted. The oil may also be applied externally, in the form of a plaster, made by incorporating one part of it with four parts of lead plaster, melted by a very gentle heat. Sometimes it appears to produce inflammation in parts distant from those to which it was directly applied. It has been said that four drops, used externally by friction around the umbilicus, will produce a purgative effect, but this is denied by Dr. Barlai, of Tuscany, who states that it is only when the oil is applied to the skin divested of the cuticle that it will operate upon the bowels.

The dose for an adult is one or two drops, and is most conveniently administered in the form of pill. A safe and convenient plan is to make two drops into four pills with crumb of bread, and to give one every hour till they operate. The oil may also be given in emulsion. The form of tincture may be advantageously resorted to when a minute quantity of the medicine is required; as it affords the means of readily dividing the dose.

Gen. Ch. Corolla four-petaled. *Calyx* two-leaved. *Capsule* one-celled, opening by pores under the persistent stigma. *Willd.*

Opium is at present generally believed to be derived exclusively from the *Papaver somniferum;* though every species of poppy is capable of yielding it to a greater or less extent, and some authors have indicated the *Papaver orientale* as its real source. The British and French Pharmacopœias unite with our own in recognising only the first-mentioned species.

Papaver somniferum. Willd. *Sp. Plant.* ii. 1147; Woodv. *Med. Bot.* p. 376, t. 138. There are several varieties of this species, of which the two most prominent are distinguished by the titles of the white and black poppy, derived from the colour of their seeds. It is the former which is usually described as the proper opium plant. The *white poppy* is annual, with a roundish, smooth, erect, glaucous, often branching stem, usually rising two or three feet in height, but sometimes five or even six feet in favourable situations. The leaves are large, variously lobed and toothed, and alternately disposed on the stem, which they closely embrace. The flowers are terminal, very large, and of a white or silver-gray colour. In India they appear in February, in Europe and the United States not earlier than June, July, or August. The calyx is smooth and composed of two leaves which fall when the petals expand. These are usually four in number; but there is a variety in which the flower is double. The germen, which is smooth and globular, supports a radiated stigma, and is surrounded by numerous short and slender filaments, with erect, oblong, compressed anthers. The capsule is smooth and glaucous, rounded, from two to four inches in diameter, somewhat flattened at the top and bottom, and crowned with the persistent stigma, the diverging segments of which are arranged in a circle upon the summit. It contains numerous minute white seeds, which, when perfectly ripe, escape through small openings beneath the stigma. In the *black poppy*, the flower, though sometimes white, is usually violet-coloured or red, the capsule somewhat smaller and more globular, and the seeds of a brown or blackish colour.

All parts of the poppy contain a white, opaque, narcotic juice; but the leaves, analyzed by M. Blondeau, yielded none of the active principles by which opium is characterized. (*Journ. de Pharm.*, vii. 214.) It is in the capsule that the juice most abounds, and the virtues of the plant chiefly reside. Hence this part is sometimes employed medicinally. (See *Papaver.*) The seeds are destitute of narcotic properties, and are even used as food. The Romans employed them in the preparation of various dainties. They abound with a bland oil, which may be extracted by expression. According to M. Berjot, the seeds yield from 46 to 50 per cent. (*Journ. de Pharm.*, Avril, 1863, p. 277.) This is an article of much importance on the continent of Europe, particularly in France and Germany. In the former of these countries, the value of the oil annually produced is said to be 25 or 30 millions of francs. (Roux, *Ibid.*, Sept. 1859, p. 202.) The oil is employed for culinary and pharmaceutic purposes, in painting and the manufacture of soap, and in other ways as a substitute for olive oil. The poppy does not appear to elaborate the milky fluid in which its narcotic properties reside before a certain period of its growth; for we are told that, in Persia, the young plants which are pulled up to prevent too thick a crop are used as potherbs; and the μηκων of the Greeks, which is believed to be identical with the Papaver somniferum, is said by Hippocrates to be nutritive.

Though generally believed to be a native of Asia, this species of poppy grows wild in the south of Europe, and even in England, whither its seeds are supposed to have been brought at a very early period. It was cultivated by the ancient Greeks, and is mentioned by Homer as a garden plant. It is at present cultivated very extensively in India, Persia, Egypt, and Asiatic Turkey, for

opium; and in several parts of Europe, especially in the northern departments of France, and in the south of Germany, mainly for the seeds. It is said that, in some parts of China, especially in the province of Szy-tschuan, notwithstanding that the drug is so abundantly imported from India, great quantities of it are produced for the supply of the masses of the people; the Bengal opium being used only by the rich. (*Neues Repertorium*, xii. 80, A. D. 1863; from *Blakiston's Five Months on the Yang-tze.*) In this country it was until recently found only in our gardens as an ornamental flower. But of late attempts have been made to cultivate it, on a somewhat large scale, with results not altogether discouraging; and the fact is worthy of observation, as having a favourable bearing on enterprises of this kind in our Northern States, that, though an idea has prevailed that a warm climate is favourable to the development of the narcotic principles in the poppy, yet the contrary would seem to be the case; and the poppy cultivated in the colder regions is really the most productive in morphia. This opinion has the support of Guibourt (*Journ. de Pharm.*, Sept. 1867, p. 222); and would seem to be established by the facts, that the opium of Anatolia is richer in morphia than that of the much hotter regions of Bengal and Upper Egypt; and that, while the best Smyrna opium seldom yields more than 12 per cent. of the alkaloid, that produced in the north of France yields from 20 to 24 per cent. (M. Bussy, *Ibid.*, p. 221.)*

* *Opium Culture in the United States.* Experiments have been occasionally made in this country, on a small scale, to determine what probability there might be that the poppy could be advantageously cultivated. One of these was made about thirty years ago by the author, who, in preparing a small medico-botanical garden for the illustration of his lectures in the University of Pennsylvania, devoted a bed to the P. somniferum, with the view of collecting the juice. The plant grew luxuriantly, and, at the proper season, upon the incision of the capsules, yielded the milky juice quite as freely as had been anticipated; but the smallness of the product, compared with the time and labour expended in obtaining it, convinced him that, with the price of labour in the United States, it would be futile to attempt the production of opium as a profitable agricultural operation.

At the meeting of the American Pharmaceutical Association in 1865, specimens of opium were presented, produced in Campbell Co., Virginia, by Mr. P. Robertson. The juice was collected in the usual way from several different species; and the specimens of the drug presented had the characteristic appearance of opium. The peculiar odour, however, was comparatively feeble. Being submitted for examination to Mr. I. J. Graham, they were found by him to contain both morphia and narcotina, but only 4 per cent. of the former, so that they could not enter into competition in the market with the imported drug. (*Am. Journ. of Pharm.*, Jan. 1867, p. 50.)

A much better product has been obtained from the white poppy, by Dr. H. Black, of Bolivar, Tenn., who has for several years given some attention to its culture. A specimen of this opium, examined by Mr. E. S. Wayne, of Cincinnati, was shown to contain 10·2 per cent. of morphia, and might well vie with the best Smyrna opium But the author has not learned that the opium was, in this instance, cultivated with a view to pecuniary profit. (*Ibid.*, Jan. 1868, p. 77.)

Within a few months, specimens of a product, intended to represent opium, have been offered to pharmaceutists in New York and Philadelphia, with a view to ascertain their real value. It was produced in Addison Co., Vermont, by Mr. W. C. Wilson, who gave the following account of his proceeding to Prof. Procter. He had a considerable extent of ground sown with seeds of the opium poppy, which grew vigorously; and about the middle of August the collection of the juice from the capsule was begun, and continued till the first of September. At this time the plants were cut down, bruised with a little alcohol for preservation, and subjected to pressure. The liquid thus obtained was evaporated, and the extract was mixed with the juice from the capsule, so as to form a soft, nearly homogeneous mass, of a pilular consistence. Some of the drug was shown to the author by Prof. Procter. It presented very much the appearance of Egyptian opium though somewhat darker, and had very decidedly the characteristic smell of genuine opium. Mr. Wilson obtained 640 pounds of this substance from 6·25 acres of land, or about 100 pounds to the acre, and received from eight to ten dollars for each pound, or about one thousand dollars an acre. Examined by Prof. Procter, the opium was found to contain in its commercial state 6·25 per cent. of morphia, and, when dried, 7·44 per cent. This sample is therefore equal to inferior specimens of Smyrna opium, though below the standard for officinal use. But it differs from genuine opium in being much more largely soluble in water. Considering that a large proportion of it consisted of an inspissated expressed juice, derived from the whole plant, which contains, according to all preceding analyses, but a very minute proportion of morphia, the portion of it derived by incision from

The process for procuring opium from the poppy, as practised by the modern inhabitants of India and Persia, according to the reports of Kerr and Kœmpfer, is very nearly the same with that described by Dioscorides as employed in his own times, about eighteen hundred years since; and the accounts of Bélon, Olivier, Texier, and more recently M. Bourlier, as to the modes of collection in Asia Minor, are not materially different. As the capsules abound most in the narcotic juice, it is from these that the opium is procured. According to Texier, a few days after the fall of the flower, men and women proceed to the fields, and make horizontal incisions in the capsule, taking care not to penetrate its cavity. A white juice exudes, and appears in the form of tears upon the edges of the incisions. The field is left in this state for twenty-four hours, after which the juice is scraped off by means of large blunt knives. A portion of the epidermis of the capsule is also removed, and constitutes about one-twelfth of the whole product. Each poppy-head affords opium but once. Thus collected, the opium is in the state of an adhesive and granular jelly. It is placed in smaller vessels, where it is beaten, and at the same time moistened with saliva. When of a proper consistence, it is wrapped in leaves, and sent into the market. (*Journ. de Pharm.*, xxi. 196.) Considerable quantities of good opium have been obtained in England by scarifying the capsules of the poppy. Similar success has been met with in France; and the drug obtained by incisions, in the latter country, has been found equal if not superior to that imported from the East.*

the capsules must be very rich in morphia; thus, as far as credit can be attached to this account, confirming the opinion elsewhere stated, that the poppy produces a much larger proportionate yield of morphia when cultivated in cold regions than in hot.* We are informed by Prof. Procter, in the article containing the foregoing account of Vermont opium, that various experiments are now going on in Mississippi and other parts of the South and West; but, if the opinion just referred to as to the influence of climate be correct, these experiments are not made under the most favourable circumstances. It will be seen that the product of the poppy in Virginia and Tennessee, as stated in preceding paragraphs, compared with that from Vermont, affords still further confirmation of the opinion. The inference from all this is, that there seems to be a fair chance for the profitable cultivation of the poppy in the more Northern States. (See *Am. Journ. of Pharm.*, Nov. 1868, p. 513.)—*Note to the thirteenth edition.*

* So early as the year 1796, a premium was awarded by the Society for the Encouragement of Arts, to Mr. Ball, for a specimen of British opium; and in 1823, Messrs. Cowley and Stains collected 196 pounds, which sold for nearly seven dollars a pound, from little more than twelve acres of land. This product, however, was by no means equal to that obtained in Scotland by Mr. John Young. From one acre of ground, planted with poppies and potatoes, he procured fifty-six pounds of opium, valued at 450 dollars, while the whole expense was more than repaid by the potatoes, and the oil expressed from the seeds. For papers on the subject of the cultivation of the poppy in England, see *Edin. Phil. Journ.* (i. 258), and the *Quart. Journ. of Science* (iv. 69).

M. Aubergier has cultivated opium in France, with encouraging results. Instead of allowing the juice after the incision to inspissate on the capsule, he collected it immediately, and dried it by artificial heat. One workman collected in a day 300 grammes (9·64 troy-ounces) of juice, which yielded one-quarter of its weight of opium. The product differed in strength very greatly, according to the variety of poppy used; the yield of morphia having varied from 3 to 17·8 per cent. He gives the preference to the *purple poppy*. (*Ann. de Thérap.*, A. D. 1852, p. 29.) See also the same work (A. D. 1853, p. 1) for an elaborate report on M. Aubergier's memoir, by a committee consisting of MM. Rayer, Orfila, and others. Attempts have been made to introduce the cultivation of opium into Algiers; and specimens of the drug produced in that country have yielded from 7 to 11 per cent. of morphia. (*Journ. de Pharm.*, Oct. 1854, p. 293.) From various communications in the journals, it appears that the collection of opium in France was on the increase; and an important fact is said to have been proved beyond doubt, that the production of the seed for oil, and of opium, may be carried on together, without injury. (*Note to former editions.*)

M. Odeph, of Luxeuil, with the view of facilitating the collection of the juice, has invented an instrument for making the incisions, which not only shortens the process,

---

* After the above statements had been printed, we had an opportunity of seeing an additional communication of Prof. Procter in the forthcoming number of the *American Journal of Pharmacy* for January, 1869 (p. 23). From this it appears that other specimens of the Vermont opium had come into the possession of Prof. Procter, who, upon a careful analysis of them, found them very different from and much inferior to that first examined; yielding, instead of 6·25 per cent. of morphia stated in the text, one of them 0·90, or less than one per cent.; the second, 0·40 per cent.; and a third, none whatever; so that, in the present state of our knowledge on this subject, the Vermont opium must be considered altogether unreliable. (*Note to the thirteenth edition.*)

Another method of extracting the virtues of the capsules is to select such as have ceased to yield their juice by exudation, to beat them with a small proportion of water, and inspissate the liquid thus obtained by artificial heat. The ancient Greeks were acquainted with both processes, as appears from the writings of Dioscorides. The term οπιον, derived from οπος, juice, they applied to the substance procured by incisions, which answers precisely to the modern opium. The inspissated expressed juice they called μηκωνιον, from μηκων, the name of the plant. Tournefort states that it is the latter preparation which is exported from Turkey as opium; the former being much more valuable, and therefore retained in the country for the use of the great and wealthy. This error has been copied by many writers on materia medica; and, till within a comparatively few years, opium was generally believed to be an extract obtained by evaporating either the expressed juice, or a decoction of the capsules.*

Commercial History. Commerce is supplied with opium chiefly from Hindostan, Persia, Egypt, and Asiatic Turkey. Immense quantities are produced in the Indian provinces of Bahar and Benares, and in the more interior province of Malwa. The opium of Hindostan is distributed extensively through continental and insular India, where it is habitually employed in the place of spirituous liquors. Great quantities are also sent to China, into which it finds an easy entrance, notwithstanding prohibitory laws. Much was formerly imported by the East India Company into England, through which a small proportion reached our own country; but it was so far inferior to that from Turkey, that it was at length excluded from the market, and none is now brought directly from the East. The great demand for it in the Indian Archipelago, and in China, and its consequent high price, have probably contributed even more than its reputed inferiority to this result. Indeed, Ainslie explicitly states that India opium is inferior to none; and it is probable that the specimens, from which the description formerly current among authors was drawn up, were the refuse of the Eastern market. We know that the drug was formerly very much and variously adulterated by the natives. Among the impurities mentioned by authors are the extract of the poppy procured by decoction, the powdered leaves and stems of the plant made into a paste with mucilage, oil of sesamum, catechu, and even cow-dung. But a more careful official inspection has resulted in a great improvement of the India opium. Of that produced in Persia, very little is brought to

but enables wholly inexperienced persons to operate, as the instrument itself regulates the depth of the incisions, so as to avoid perforating the wall of the capsule, thereby impeding the growth of the plant, and consequently the maturing of the seeds. (*Ann. de Thérap.*, 1866, p. 2.) Very recently M. Lallier, in a memoir presented to the Academy of Sciences, states that the production of opium has not of late been extending in France, in consequence of the uncertainty of the weather; rains often coming on at the moment when the incisions are made, so as to wash away the juice, and thus destroy the harvest. To obviate this, M. Lallier proposes that the plants should, at the proper season, be pulled up and carried under cover, where, by immersing their roots in water, they will yield not only as much as in the usual mode, but even more, while the seeds ripen as well, and yield as much oil as when the plant ripens in the soil. (*Journ. de Pharm. et de Chim.*, Oct. 1867, p. 274.)—*Note to the thirteenth edition.*

In Armenia, where opium is largely produced, four varieties of seeds are used, the white, yellow, black, and sky-blue. The flower produced by the white seeds is white, that by the yellow is red, that by the black is black, and that by the sky-blue is deep-purple. The white and sky-blue seeds yield large, somewhat oblong capsules, like citrons in shape; the yellow, and black, small and round capsules. For an extent of ground forty paces square, forty drachms of seeds are required. Each head yields about a grain of opium. The operators, not accustomed to the work, are apt to become intoxicated or stupefied during the period of harvest. (Gaultier de Claubry, *Journ. de Pharm.*, 3e sér., xiii. 105.)

A very interesting paper, by Mr. S. H. Maltass, on the cultivation and collection of opium in Turkey, and its preparation for the market, affording minute information on these points, is contained in the *Pharm. Journ. and Trans.* for March, 1854 (p. 395).

* For the most recent details in relation to the opium culture in Anatolia or Asia Minor, the reader is referred to an article by M. E. R. Hefter, of Smyrna, in the *Am. Journ. of Pharm.* (July, 1868, p. 362), originally published as a pamphlet in that city in April, 1868. Any one disposed to engage in the business of cultivating opium in the United States would do well to consult this paper. (*Note to the thirteenth edition.*)

this country; and it is scarcely known in our market as a distinct variety. Much was formerly produced in Upper Egypt, especially in the district of ancient Thebes, which was supposed to yield it in greatest perfection. Hence it was long known by the name of *Opium Thebaicum*, and laudanum is still frequently directed in prescriptions as *Tinctura Thebaica*. Its cultivation has been again introduced into Egypt; and considerable quantities are exported.

Turkey opium is produced in Anatolia, and shipped chiefly from the port of Smyrna. It is brought to the United States, either directly from the Levant, or indirectly through different European ports. From the treasury returns for the years from 1827 to 1845 inclusive, according to a table prepared by Dr. J. B. Biddle, and published in the *American Journal of Pharmacy* for April, 1847, it appears that the average value of the annual importations for the period referred to was from Turkey 128,137 dollars, from England 13,744, from France 4470, and from all other places 6607 dollars. Of this amount so much was exported as to leave, for the average annual consumption of the country, the value of 66,809 dollars. In the year ending June 30, 1862, the value of the opium import is stated, in the N. Y. *Journal of Commerce*, to have increased to 932,887 dollars. Of this amount, however, 281,796 dollars' worth was imported into California, to supply the wants of the Chinese population of that region; and the medical necessities of our vast armies were responsible for much of the increase. (*Am. J. of Pharm.*, Sept. 1865, p. 393.) Turkey opium usually comes to us in masses of irregular size and shape, generally more or less flattened, covered with leaves, or the remains of leaves, and with the reddish capsules of some species of *Rumex*, which are said to be absent in the inferior kinds, and may, therefore, be considered as affording some indication of the purity of the drug. We may account for this circumstance upon the very probable supposition, that these capsules are removed during the operation which the masses undergo in the hands of the merchants after leaving those of the cultivators. We are told by the French writers that extensive frauds are practised at Marseilles in this branch of commerce. The opium taken thither from the Levant is first softened, and then adulterated with various matters which are incorporated in its substance. To use a strong expression of M. Guibourt, they make the opium over again at Marseilles. Our traders to the Mediterranean would do well to bear this assertion in mind. According to Dr. A. T. Thomson, one-fourth part of Turkey opium generally consists of impurities. Sand, ashes, the seeds of different plants, extracts of the poppy, *Lactuca virosa*, *Glycyrrhiza glabra*, and *Chelidonium glaucum*, gum arabic, tragacanth, salep, aloes, even small stones, and minute pieces of lead and iron, are mentioned among the substances employed in the sophistication of the drug. Mr. Landerer, of Athens, was informed by a person who had been engaged in the extraction of opium, that grapes, freed from their seeds and crushed, were almost universally mixed with the poppy juice, and that another adulteration consisted of the epidermis of the capsules and stem of the plant, pounded in a mortar with the white of eggs. (See *Am. Journ. of Pharm.*, xv. 238.) According to Mr. Wilkins, who witnessed the collection of opium, the inspissated juice of the grape, thickened with flour, is often used for the same purpose. (*Pharm. Journ.*, xiv. 400.) In England a sophisticated opium was some years since prepared, which, though so nearly resembling good Turkey opium in appearance that by the eye alone it was difficult to detect the fraud, was yet wholly destitute of the active principle of the drug. Portions of it were sent into the markets both of France and this country. A sample of a similar drug, perhaps the same, was examined by Prof. Aikin, Examiner of drugs for the port of Baltimore, and found to contain but 1·10 per cent. of morphia. (See *Am. Journ. of Pharm.*, July, 1859, p. 374.) It was probably the genuine drug, deprived of its morphia by some process which did not materially disturb the visible arrangements of its particles.* (*Ibid.*, x. 261.)

* The great importance of opium renders it desirable that all its commercial varieties should be accurately described, and their relative value so far as possible ascertained.

Opium is regarded as inferior when it has a blackish colour; a weak or empyreumatic smell; a sweet or slightly nauseous and bitter taste; a soft, viscid, or greasy consistence; a dull fracture; or an irregular, heterogeneous texture,

The following statement has been drawn up from the most recent published accounts of the drug, and from the personal observations of the author.

The varieties of this drug may be arranged, according to the countries in which they are produced, under the heads of *Turkey*, *Egyptian*, *India*, and *Persia opium*.

I. TURKEY OPIUM. This title belongs to the opium produced in the Turkish province of Anatolia, and exported from Smyrna and Constantinople. According to some authorities, there is no essential difference between the parcels of the drug brought from these two ports. Others maintain that they are distinct varieties, differing in their interior structure, and probably also in the precise place of their production, and the mode of their collection. The truth probably is, that most of the opium shipped at Constantinople is produced in the more northern parts of the opium districts of Anatolia, while that from Smyrna is collected in the provinces more convenient to the latter city; and, though it is possible that an identical drug may often be brought from the two ports, yet there are grounds for arranging it under different varieties, as derived from these different sources. It is said also that a portion of opium which is taken to Constantinople is produced in Macedonia in Europe, which must therefore be added to the opium-producing regions. (*Neues Repert.*, xvi. 751, A. D. 1867.)

1. *Smyrna Opium.* This is the variety which is, beyond all comparison, most abundant in our markets; and it is from this that the ordinary descriptions of opium are drawn up It comes to us in masses of various size, usually from half a pound or somewhat less to a pound in weight, sometimes, though rarely, as much as two or even three pounds, originally, perhaps, of a globular form, but variously indented, and rendered quite irregular in shape by the pressure to which they have been subjected, while yet soft, in the cases which contain them. Sometimes they are even pressed out into flat cakes. As brought into market, the lumps are usually hard on the outside, but still soft within. They are covered externally with the remains of leaves, and with the reddish capsules of a species of Rumex, which have no doubt been applied in order to prevent the surfaces from adhering. Notwithstanding, however, this coating, the masses sometimes stick together, and two or more become consolidated into one. In this way the fact may be accounted for, that the seeds of the Rumex are occasionally found in the interior of the masses. In the finer parcels of Smyrna opium, the colour internally is light-brown: in the inferior it is darker. A peculiar character of this variety is that, when a lump of it is cut into and then carefully torn, numerous minute shining tears are observable, particularly under a microscope, bearing some resemblance to small seeds, but readily distinguishable by pressure between the fingers. They are undoubtedly formed from the drops of juice which escape from the incisions in the capsules, and which, according to Bélon, are allowed to concrete before they are removed. From the account of the same author it appears that, after the juice has been collected, it is not subjected to the process of kneading or beating, as in the case of other varieties of opium; so that the tears preserve their original shape in the mass. It is probably owing to the peculiar mode of collecting Smyrna opium, that minute pieces of the skin of the poppy capsules are found intermingled in the mass: these being separated in the process of removing the adhering tears. In the best specimens of Smyrna opium, these fragments of the capsules are the only impurities. This variety of the drug is of very different qualities; the finest kinds yielding, according to Merck, as much as 13 per cent. of pure morphia, while from some very bad parcels he could not procure more than 3 or 4 per cent. In these inferior specimens the colour is darker, the smell is often musty, and there is very generally more or less mouldiness both upon the surface, and in the interior of the masses, indicating perhaps too much moisture in the opium originally, or its subsequent exposure to an injurious degree of dampness. Good Smyrna opium ought to yield 10 or 11 per cent. of morphia. Dr. Christison, however, states that he has not been able to procure more than 9 per cent. from the finest Smyrna opium.*

2. *Constantinople Opium.* Most of the Constantinople opium is in lumps from half a pound to two and a half pounds in weight, and scarcely distinguishable in exterior appearance from those of the former variety, being equally irregular in shape, and in like manner covered with the capsules of the Rumex. According to Merck, however, it often differs strikingly from the Smyrna opium in its interior constitution, being wholly des-

* According to Landerer, little of the opium is produced in the immediate neighbourhood of Smyrna; the greater portion being brought to that port, on the backs of camels, from a distance of from ten to eighteen days' journey. (*Journ. de Pharm.*, 3e sér., xxiii. 33.) The same writer states that the opium is chiefly prepared at Kara Chissar, near Magnesia. The incisions are generally made before sunrise. The juice is partly caught in mussel-shells, and dried in the sun. This is considered the best. Every evening the juice which has dried upon the capsules is scraped off, with a portion of the epidermis. The poppy is then cut down, and stripped of its leaves, which are boiled in water; and the liquor is evaporated to the consistence of an extract. With this the inspissated juice is incorporated, and the mixture is then formed into cakes, wrapped in poppy leaves, and placed on shelves to dry. (See *Am. Journ. of Pharm.*, xxiii. 251.) It is very evident, from the interior structure of the *best Smyrna opium*, that it has not been prepared in the way described by Landerer; though his account is probably true in reference to inferior varieties of the drug. (*Note to the tenth edition.*)

from the intermixture of foreign substances. It should not impart a deep-brown colour to the saliva, nor leave a dark uniform trace when drawn over paper, nor form with water a thick viscid solution.

titute of the tears which characterize that variety. This would indicate some difference in the mode of collecting and preparing the juice. In the case of the Constantinople opium, it is probably removed from the capsules before concretion. Merck says that he has not discovered, in this variety, those minute portions of the poppy capsules which are usually present in Smyrna opium. The average quality of the Constantinople opium, as above described, is about equal to that of the drug from Smyrna; but it appears to be occasionally purer; as Merck obtained from one specimen as much as 15 per cent. of pure morphia. Dr. R. Bauer, of Constantinople, who has for many years had the opportunity of becoming familiar with the different varieties of opium which reach that city, denies that at present any of the varieties produced near Smyrna contain tears, except the single one from Magnesia. (*Neues Repert.*, xvi. 751, A. D. 1867.)

In an account, by M. Bourlier, of the culture of the poppy and collection of opium in Bithynia, a province of Asia Minor, near Constantinople, it is stated that the lumps, when formed out of the concrete juice, are enveloped in poppy leaves; and no mention is made of the use of the Rumex capsules to prevent adhesion. It is the opium here collected, which, according to M. Bourlier, is known throughout the Levant and in Europe as Constantinople opium. On the same authority it is stated that the yelk of eggs is sometimes largely used for adulterating opium; a fraud which may be detected by the large proportion of fatty matter which the adulterated drug yields to ether, and by the impossibility of drying it so as to fit it for pulverization. (*Annuaire de Thérap.*, A. D. 1859, p. 4)

Guibourt describes another variety of Constantinople opium of much inferior character. "It comes," he observes, "in small flattened cakes, sufficiently regular and of a lenticular shape, from two to two and a half inches in diameter, and always covered with a poppy leaf, the midrib of which divides the surface into two equal parts. It has an odour similar to that of the preceding variety, but feebler, and it blackens and dries in the air. It is more mucilaginous than Smyrna opium, and contains only half as much morphia." These characters are obviously those of Egyptian opium; and, though the parcels which came under the notice of Guibourt may have been imported directly from Constantinople, it is highly probable that they were originally from Alexandria. Mr. Stettner, of Trieste, though well acquainted with the opium commerce of that port, admits no such Constantinople opium as that described by Guibourt. (*Annal. der Pharm.*, xxiv. 65.) According, however, to Dr. Bauer, the opium collected in the districts nearest Constantinople is mostly in small pieces, often of only 2 or 3 ounces, which are always invested with poppy leaves, or more rarely with grape leaves, generally smooth, and without Rumex capsules; and this description corresponds with Guibourt's. (*Neues Repert.*, xvi. 754, A. D. 1867.)

II. EGYPTIAN OPIUM. This is in flat roundish cakes, of various dimensions, sometimes as much as six inches in diameter, and a pound in weight, usually, however, much smaller, and sometimes not weighing more than half an ounce. These cakes are either wrapped in a poppy leaf, so placed that the midrib divides the surface into two equal parts, or exhibit vestiges of such a covering. Occasionally the brown colour of the opium is seen through the leaf, and the surface appears as if uncovered, while the leaf is still present. This variety of opium is always destitute of the Rumex capsules, and differs from the Smyrna opium also in being brittle instead of tenacious, and equally hard in the centre as at the surface of the mass. Its fracture is conchoidal and of a waxy lustre, and small fragments of it are translucent. Its colour is usually redder than that of Smyrna opium, though sometimes dark. Some of the pieces, on exposure to the air, become damp and sticky on the surface, indicating the fraudulent addition of a deliquescent substance. The odour is similar to that of Smyrna opium, but weaker. It is an inferior variety; as the best of it, examined by Merck, yielded only 6 or 7 per cent. of morphia; and a specimen of it was found by Mr. J. Evans, of Philadelphia, to contain not more than 3·55 per cent. Egyptian opium, therefore, should never be dispensed by the apothecary, or employed in the preparation of his tinctures; as the prescription of the physician is based upon the strength of good Smyrna opium, which is about twice that of the Egyptian.

M. Gastinel, residing in Cairo, under the stimulus apparently of the works of Aubergier, is making efforts for improving the production of opium in Egypt, by which it is hoped that the reputation which the product of this region formerly possessed may be restored. (*Ann. de Thérap.*, 1866, p. 3.) That the deficiency of morphia in Egyptian opium is not ascribable to the climate, would seem to be proved by the fact, reported to the Paris Society of Pharmacy, by M. Gastinel, director of the garden of acclimation at Cairo, that he has produced opium in a garden of his own, containing 12 per cent. of morphia. (*Journ. de Pharm. et de Chim.*, 4e sér., iv. 415, A. D. 1866.)

III. INDIA OPIUM. Little if any of this opium reaches our market. There appear to be two chief varieties of it; one produced in Bahar and Benares, in the Bengal Presidency, and called *Bengal opium*, the other in the interior provinces, and designated by the name of *Malwa opium*.

1 *Bengal Opium.* For a minute account of the cultivation and preparation of this variety

Properties. Good opium has a peculiar, strong, narcotic odour, and a bitter, somewhat acrid taste. When long chewed it excites much irritation in the lips and tongue, and may even blister the mouth of those unaccustomed to its use.

of opium, the reader is referred to elaborate papers by Dr. Eatwell, of Calcutta, contained in the eleventh and twelfth volumes of the *London Pharmaceutical Journal and Transactions*, an abstract of which will be found in the *Am. Journ. of Pharm.* (xxiv. 118), and in the last edition of Pereira's *Materia Medica* (vol. ii. p. 1009, Am. ed.). Bengal opium is identical with the variety sometimes called *Patna opium*. It is in round balls, weighing three pounds and a half, invested by a coating half an inch thick, composed of agglutinated leaves and poppy-petals. The interior of the mass is of a brownish-black colour, of the consistence of a stiff paste, and possessed in a high degree of the characteristic odour and taste of opium. The proportion of active matter in this opium varies somewhat with the season and in the different specimens. From a table given by Dr. Eatwell, it appears that the percentage of morphia varies from 2·17 to 3·67, and that of narcotina from 3·85 to 5·70. Prof. Procter found a specimen of Patna opium to yield about 5 per cent. of morphia. (*Am. Journ. of Pharm.*, xxi. 194.) It is, therefore, much inferior to the best Smyrna opium in its yield of morphia, while it is richer in narcotina. Yet Christison states that all the India opium which he has seen is exempt from the mixture of leaves, seeds, and fragments of poppy capsules so abundant in Smyrna opium. Its inferior character is possibly, in some degree, owing to the circumstance, that the juice, after collection, is kept for some time before it is made up, and consequently undergoes fermentation. Prof. Carson, of the University of Pennsylvania, in describing a specimen of this variety in the *Am. Journ. of Pharm.* for July, 1849 (p. 194), speaks of acicular crystals, which he had noticed by the aid of the microscope; and he informs me (Sept. 1864), that on recently examining a specimen of the same opium, now perfectly dry, he found similar crystals. No such crystals, he states, are to be found in Smyrna opium.

The India opium examined by Dr. A. T. Thomson was apparently of inferior character. As described by that author, it was in round masses, covered with the petals of the poppy in successive layers, to the thickness of nearly one-fourth of an inch. It had a strong empyreumatic smell, with little of the peculiar heavy odour of Turkey opium. Its taste was more bitter and equally nauseous, but less acrid. Its colour was blacker, and its texture, though as tenacious, was less plastic. It was more friable, and, when triturated with water, was wholly suspended or dissolved, leaving none of that plastic residue which is afforded by the other variety. It yielded to Dr. Thomson more narcotina than Turkey opium, but only about one-third the quantity of morphia. All these are the characters of an extract of the poppy heads, rather than of their inspissated juice. The absence of the plastic principle analogous to caoutchouc is strong evidence in favour of this view of its nature; for it is obvious that water would not extract this principle from the capsules, while it is hardly probable that the juice is destitute of it. Besides, the strength indicated by Dr. Thomson is very nearly the same with that of the extract of the capsules prepared in France. Bengal opium is at present superior to that here described, though still inferior to the Smyrna opium.

There is a variety of Bengal or Patna opium, called *garden Patna opium*, which was described in the fifth edition of this work, on the authority of Dr. Christison, as Malwa opium. Dr. Christison has subsequently ascertained its true origin. It is prepared in Bahar with peculiar care, from juice which has not been suffered to undergo fermentation. It is in cakes three or four inches square, and about half an inch thick, which are packed in cases with a layer of mica between them. These cakes are without covering, hard, dry, and brittle, of a uniform shining fracture, and not unlike an extract in appearance. The colour is sometimes almost black, and sometimes of a light-brown, not unlike that of Egyptian opium. Dr. Christison states that it is much superior to the globular Bengal opium, and that some specimens are little inferior to Turkey opium in the proportion of morphia.

2. *Malwa Opium.* This is in flat, roundish cakes, five or six inches in diameter, and from four to eight ounces in weight. They are commonly quite hard, dry and brittle, of a light-brown colour, a shining fracture, a compact homogeneous texture, and free from mechanical impurities. The quality is superior to that of common Bengal opium. (*Christison's Dispensatory.*) A specimen of Malwa opium, described by Dr. Carson (*Am. Journ. of Pharm.*, xxi. 195), broke with a short rough fracture, which was of a blackish-brown colour, here and there showing irregular oily spots. Prof. Procter obtained from it 9¼ per cent. of morphia.

An essay on the antiquity of the opium culture in India, the cultivation of the drug in that region, its collection, commerce, qualities, adulterations, &c., by M. Créteur, contained in the *Annuaire de Thérapeutique* for 1868 (p. 1), gives the most recent information on these points from personal observation. The author states that a specimen of good India opium yielded him about 10 per cent. of morphia, and expresses his conviction that this variety of opium will again enter into the commerce of Europe.

IV. PERSIA OPIUM. A variety of opium under this name has sometimes existed in the markets of London, and has even found its way to this country, though it is very rare. Recently it is said to have reached Europe in considerable quantities, and has received

Its colour is reddish-brown or deep-fawn; its texture compact; its sp gr. 1·336. When drawn over paper it usually leaves an interrupted trace of a light-brown colour. It is often soft in the interior of the mass, and in this state is tenacious; but when exposed to the air it gradually hardens, and ultimately becomes brittle, breaking with a shining fracture, and affording, when pulverized, a yellowish-brown powder, which becomes adhesive upon a slight elevation of temperature. It readily inflames upon the application of a lighted taper. It yields its virtues to water, alcohol, and diluted acids, but not to ether. To all these menstrua it imparts a deep-brown colour. Alcohol dissolves about four-fifths of it. Pelletier states that the proportion taken up by water varies in all specimens. He never found the quantity of extract prepared with cold water to exceed 12 parts out of 16. (*Journ. de Pharm.*, Nov. 1832.)

especial attention in France. It is in different forms. The most common is in cylindrical pieces, about three and a half inches long, and half an inch thick, wrapped in glossy paper, and tied with a cotton thread, and each weighing about half an ounce. It is of a uniform consistence, but exhibits, nevertheless, under the microscope, small agglutinated tears, much less than those of Smyrna opium. It has the liver-brown colour of Egyptian opium, a virose, musty odour, and a very bitter taste, and, like Egyptian opium, softens in a moist atmosphere. According to Dr. Reveil, it contained 15 per cent. of glucose. The first specimens were brought to England from Trebizond on the Black Sea; but their precise origin was not known. Three other forms of Persia opium have been described by Dr. Reveil, as they were offered to his notice in Paris. *One* was in spherical cakes, without envelope or Rumex capsules. In physical characters, it closely resembled the cylindrical variety, though softer and more hygrometric. It had a strongly virose odour, and a bitter slightly sweetish taste. The *second* was in irregular masses, liver-coloured, of a virose smell and bitter taste, brittle, smooth and shining, compact, and very hygrometric. The *third* was in the form of flat cakes, covered with an unknown leaf with some Rumex capsules, of a reddish-brown colour, tasting and smelling like the preceding, compact, and smooth. Of these the first and third contained, each, 31·6 per cent. of glucose; the second 13·9 per cent.

All these varieties were remarkable by the absence of obvious impurities, such as are insoluble in water and alcohol. From 75·2 to 84·2 per cent. was soluble in water, from 71·6 to 81·6 in alcohol at 85°. The *cylindrical* variety yielded 8·15 per cent. of morphia; the *spherical* 6·4 per cent.; the *irregular* 7·1 per cent.; and the *flat and coated* 5·10 per cent. The presence of glucose in such large proportions may be explained by the asserted fact that honey is sometimes mixed with opium at the time of its collection. Though the proportion of morphia is considerable in these varieties, yet, in consequence of their large proportion of soluble matter, they yield comparatively feeble extracts. (*Journ. de Pharm.*, Août, 1860, p. 101.) Since M. Reveil's investigation, two samples of Persia opium have been examined by M. Séput of Paris, one of which yielded 9·33 and the other 9·37 per cent. of morphia. (*Ibid.*, Mars, 1861, p. 163.) From the report of a trial in New York, published in the *Journal of Commerce*, it appears that a parcel of Persia opium, imported into that city from London in 1835, was in small round balls, and contained only 3 per cent. of morphia.

Relative strength of the varieties of opium. It is highly important that the real value of these commercial varieties should be known; as otherwise there can be no certainty in relation to the strength of the preparations which may be made from them. In the preparation of laudanum and the other tinctures into which opium enters, it is understood that the drug employed should have the average quality of good Smyrna opium. The inferior kinds should be used only for the extraction of morphia. M. Guibourt has published a series of investigations into the richness in morphia of different varieties of opium, giving the percentage yielded in the soft, the hard, and the dried states. The following table contains an abstract of his results. It is obvious that he operated only on fair specimens of the several varieties.

		Soft	Hard.	Dried.
Anatolia (Smyrna) opium	lowest	9·60 per c.	10·82 per c.	11·70 per c.
do. do. do.	highest	18·24	19·77	21·46
do. do. do.	mean	12·40	13·57	14·78
Constantinople do.	lowest	10·90	13·32	14·40
do. do.	highest	14·00	15·72	17·00
Egyptian do.	lowest		5·19	5·81
do. do.	highest		11·45	12·21

do. do.	mean		16·77	17·69

(*Journ. de Pharm.*, Janv., Fév., et Mars, 1862.)—*Note to the twelfth edition.*

Much attention has been devoted to the chemical constitution of opium. It was by their researches into the nature of this substance that chemists were led to the discovery of those vegetable alkaloids, which, as the active principles of the plants in which they are found, have attracted so much notice, and been applied so advantageously to the treatment of disease. To Sertürner, an apothecary at Eimbeck, in Hanover, belongs the credit of having opened this new and most important field of experiment. In the year 1803, M. Derosne made known the existence of a crystallizable substance which he had discovered in opium, and which he erroneously believed to be the active principle. In the following year, Seguin discovered another crystallizable body, which experience has proved to be the true narcotic principle of opium; but he did not fully investigate its nature, and no immediate practical advantage accrued from his excellent analysis. About the same time Sertürner was engaged in a similar investigation, the results of which, very analogous to those obtained by Seguin, were published in a German journal, without, however, attracting general attention. In this state the subject remained till 1817, when Sertürner announced the existence of a saline compound in opium, consisting of a peculiar alkaline principle united with a peculiar acid, and clearly demonstrated the precise nature of a substance, which, though before discovered both by Seguin and by himself, had been hitherto but vaguely known. To the alkaloid, in which he correctly conceived the narcotic powers of opium to reside, he gave the name of *morphium*, which has been subsequently changed to *morphia*, in order to render it conformable with the titles of the other alkalies. The acid he called *meconic*, a term derived from the Greek name of the poppy. The correctness of the statements of Sertürner was confirmed by Robiquet, who also satisfactorily demonstrated that the substance obtained by Derosne, and called by him the *salt of opium*, was a principle altogether distinct from morphia, though supposed to possess considerable influence over the system. In the belief of its narcotic powers, Robiquet denominated it *narcotin*, a title which it still retains. Several other peculiar principles have since been discovered; though it is difficult to resist the impression, that some of them may be the result of the processes to which opium is submitted for their extraction. According to the views of its constitution at present admitted, opium contains, 1. morphia; 2. narcotin or narcotina; 3. codeia; 4. paramorphia; 5. papaverina; 6. opiania; 7. narcein or narceia; 8. *pseudomorphia;* 9. meconin; 10. porphyroxin; 11. meconic and sulphuric acids; 12. a peculiar acid not yet fully investigated, perhaps the thebolactic acid recently discovered by the Messrs. Smith, of Edinburgh; 13. extractive matter; 14. gum; 15. bassorin; 16. glucose; 17. a peculiar resinous body insoluble in ether and containing nitrogen; 18. fixed oil; 19. a substance resembling caoutchouc; 20. an odorous volatile principle; together with lignin, and a small proportion of acetic acid, sulphate of lime, sulphate of potassa, alumina, and iron. In relation to their optical properties, all the organic bases of opium produce deviation of the plane of polarization to the left. (Bouchardat and Boudet, *Journ. de Pharm.*, 3e sér., xxiii. 294.)*

* Glucose, mentioned in the text as one of the ingredients of opium, has but recently been proved to exist normally in the drug. M. Lakens, of Toulouse, has found it in a tincture of poppy capsules, and in all the commercial varieties of opium, in proportions varying from 3 to 14·5 per cent. This fact is of some importance in reference to the use of grape-juice in the adulteration of opium, showing that the presence of glucose, even in considerable quantity, must not be considered as a proof of sophistication. (*Journ. de Pharm.*, Oct. 1854, p. 265.)

Besides the components of opium above enumerated, notice has been given by Dr. G. C. Wittstein of the discovery of another alkaloid, which, from its near alliance to morphia, he proposes to name *metamorphia*. We shall give a brief notice of it here, until its claims shall have been established by further investigation. If we count the pseudomorphia of Pelletier, it is the ninth alkaloid which has been extracted from opium.

Metamorphia. This was obtained by Wittstein from a substance separated from the dregs of laudanum, in an attempt to prepare morphia from them by Mohr's method with lime. By crystallization fine white silky needles were obtained, which consisted of the hydrochlorate of a new alkaloid. This was separated by exactly saturating with sulphate of

Of the principles above mentioned *morphia* is by far the most important. It is generally admitted to exist in opium united with meconic acid in the state of meconate, and to a certain extent also as a sulphate. Of morphia and its preparations we shall treat under another head. (See *Morphia.*)

Narcotina or *narcotin* receives one or the other of these names, according as it is considered alkaline or neuter. It exists in opium, chiefly at least, in the free state, and is left behind in considerable quantity when the drug is macerated with water. It is white, tasteless, and inodorous; and crystallizes in silky flexible needles, usually larger than the crystals of morphia, fusible at 240° and volatilizable at 310° (*W. A. Guy*),* insoluble in cold water, soluble in 400 parts of boiling water, in 100 parts of cold and 24 of boiling alcohol which deposits it upon cooling, and very soluble in ether. The fixed and volatile oils, and the diluted acids, also dissolve it; and it has recently been found to be soluble in the volatile oil of turpentine, which, aided by heat, will extract it from opium, and yield it in crystals by evaporation. (*Journ. de Pharm. et de Chim.*, 4e sér., ii. 156.) As it exerts no alkaline reaction upon vegetable colours, and does not prevent the acids from reddening litmus paper, there would appear to be some reason for denying it the rank of an alkali. But it unites with some of the acids forming definite compounds, which may be procured in a separate state; and Robiquet obtained the sulphate and muriate of narcotina well crystallized. (*Journ. de Pharm.*, xvii 639, and xix. 59.) Hence many chemists, among whom is Berzelius, consider it alkaline; and, perhaps, this view of it is the most convenient. It must be admitted, however, to have a very feeble neutralizing power. With acetic acid it does not appear to form a permanent combination; for, though dissolved by cold acetic acid, it is separated by heating the solution. Narcotina consists of carbon, hydrogen, nitrogen, and oxygen; and its formula, as given by Hinterberger, is $C_{44}H_{23}NO_{14}$. According to Messrs. Matthiessen and Foster, it contains the elements of cotarnin and meconin. It may be distinguished from morphia by its insipidity, solubility in ether, and insolubility in alkaline solutions, by not affecting vegetable colours, by assuming a yellowish instead of a blood-red colour under the action of strong nitric acid, by not decomposing iodic acid, and by not producing a blue colour with the

silver, and macerating the precipitate with carbonate of baryta. The alkaloid was extracted by alcohol, and, after evaporation, was obtained in hard flat prisms, arranged in a stellate form. The crystals were fused by heat, but at the same time decomposed. They were dissolved by about 6000 parts of cold and by 70 of boiling water, by 9 parts of boiling and 330 of cold alcohol of 90 per cent. The alcoholic solution had a sharp, bitter taste, and a feeble alkaline reaction. The alkaloid was insoluble in ether, but rapidly soluble in solution of potassa, somewhat less so in ammonia, and soluble also in the alkaline carbonates, especially with the aid of heat. Nitric acid instantly coloured the crystals orange-red, and formed a yellow solution. A concentrated solution of iodic acid gradually produced a yellow colour with its aqueous solution, and a purple colour in starch paper suspended above it. The aqueous solution is not disturbed by sesquichloride of iron, is rendered grayish-black by nitrate of silver, and causes gradually a yellow turbidness in solution of terchloride of gold, which results in a brownish precipitate. It was not subjected to elementary analysis. From its origin in the dregs of laudanum, it appears to us most probable that it was the result of chemical change in morphia. (*Chemisches Central Blatt*, no. 61, p. 966; see also *Am. Journ. of Pharm.*, Jan. 1861, p. 24.) Dr. Fronmüller found Wittstein's metamorphia to be soporific in doses of half a grain. (*Ibid.*, Sept. 1861, p. 408.)—*Note to the twelfth edition.*

Proportionate quantity of the more important constituents of Opium. The following are given as the relative quantities of the ingredients mentioned, obtained by the Messrs. Smith, of Edinburgh, from 100 parts of fine opium: 10 parts of morphia, 6 of narcotina, 0·15 of thebaina, 1 of papaverina, 0·3 of codeia, 0·02 of narceia, 0·01 of meconin, 4 of meconic acid, and 1·25 of thebolactic acid. (*Pharm. Journ. and Trans.*, Oct. 1865, p. 183.)—*Note to the thirteenth edition.*

* The results here given, on the authority of Mr. Wm. A. Guy, as regards the fusing and subliming points of the alkaloids, were obtained through a very careful application of heat, in a special manner, and are recorded in the *Pharm. Journ. and Trans.*, Feb. 1868, p. 374. It should be noticed, however, that, in the process of sublimation, the alkaloids undergo a partial decomposition, leaving a more or less copious carbonaceous residue, by which, as he observes, the alkaloids and glucosides are distinguished from most other bodies. (*Note to the thirteenth edition.*)

salts of iron. It is, however, reddened by a mixture of nitric and sulphuric acids. Hence, if to a mixture of it with strong sulphuric acid a small piece of nitre is added, a deep blood-red colour is produced; while morphia, under the same circumstances, yields a brownish or olive-green colour. It gives a greasy stain to paper when heated upon it over a candle. Heated with an excess of sulphuric acid and deutoxide of manganese, it is converted into an acid called *opianic acid*, and into a substance of feeble alkaline properties, which has received the name of *cotarnin* (*cotarnia*). (*Journ. de Pharm*, 3e sér., vi. 99.) Meconin is said also to be among the results of its decomposition by oxidizing agents. When distilled with potassa, it yields a colourless volatile liquid having alkaline properties, with the strong smell of herring-pickle together with that of ammonia. This is a peculiar alkaloid, and has received the name of *propylamin*. (Wertheim, *Pharm. Cent. Blatt*, June 1, 1850, p. 421, and Dec. 17, 1851, p. 918.)* Water extracts narcotina partially from opium, in consequence of the acid which the latter contains, either free or combined with the narcotina. It is usually obtained mixed with morphia in the processes for procuring that principle; and may be separated by the action of ether, which dissolves it without affecting the morphia, and yields it upon evaporation. It may also be obtained by digesting opium in ether, and slowly evaporating the ethereal solution, which deposits crystals of narcotina. It is said that the same result may be obtained by using the oil of turpentine as the menstruum, first heating it with opium, and then evaporating the solution. Another mode of procuring it is to treat opium, exhausted by previous maceration in water, with dilute acetic acid, filter the solution, precipitate by an alkali, wash the precipitate with water, and purify it by solution in boiling alcohol, from which it crystallizes as the liquid cools. Should it still be impure, the solution in alcohol and crystallization may be repeated.

The proportion of this principle found in opium varies extremely in the different varieties, and in different specimens of the same variety. Thus in Smyrna opium it has been found, according to different observers, in quantities varying from 1·30 to 9·36 per cent.

Though narcotina itself is tasteless, its salts are very bitter, even more so than those of morphia. (*Berzelius.*) Their solution reddens litmus, and yields precipitates with the alkalies and infusion of galls. It has already been stated that Robiquet obtained the sulphate and muriate crystallized.

Different opinions have been advanced relative to the action of narcotina on the system. Derosne believed it to be the active principle of opium; though, upon experimenting with it, he obtained effects but little stronger than those produced by an equal dose of opium itself. Others found it possessed in different degrees of narcotic properties; and the results of various experiments which led to this conclusion may be seen in former editions of this work. But a more thorough investigation has led to the conclusion that it cannot be ranked among narcotic medicines. It is now pretty well established that narcotina is identical with aconella, an alkaloid recently extracted by the Messrs. Smith of Edinburgh from aconite. (See *page* 73.) The effects of a narcotic character which have

* There would seem, from the observations of Wertheim and Hinterberger, to be four homologous modifications of narcotina, having a fixed relation to each other in composition, the number of eqs. of nitrogen and oxygen being the same in all, while those of carbon and hydrogen increase by 2 eqs. in regular progression. Thus 1. *normal narcotina* (Hinterberger) has the formula $NC_{42}H_{21}O_{14}$; 2. *methylic narcotina* (Wertheim) $NC_{44}H_{23}O_{14}$; 3. *ethylic narcotina* (Wertheim) $NC_{46}H_{25}O_{14}$; and 4. *propylic narcotina* (Wertheim) $NC_{48}H_{27}O_{14}$. Another interesting point is that each of these yields a peculiar volatile alkaloid by distillation with potassa; and the several products bear to each other the same chemical relation as exists between the fixed alkaloids from which they are derived. They are *ammonia* from the first, *methylamin* from the second, *ethylamin* from the third, and *propylamin* from the fourth. The last of these volatile alkaloids has been referred to in the text as having the smell of herring-pickle. It has been produced also by distilling ergot with potassa. Methylamin was procured by Wertheim. The other products are, we believe, thus far hypothetical. (*Pharm. Cent. Blatt*, Dec. 17, 1851, p. 918, and *Journ. de Pharm.*, 3e sér., xxiii. 154.)—*Note to the tenth edition.*

been attributed to it, have probably arisen from the employment of a preparation not entirely freed from other principles contained in the opium. Indeed, so little has it of this character, that the name of *anarcotina* has been proposed for it, expressive of its total want of narcotic power. Dr. O'Shaughnessy, Professor of Chemistry in the Medical College of Calcutta, recommends narcotina very highly in intermittent fever, and believes that he has discovered in it even stronger antiperiodic properties than those of quinia. In the cases reported by him, it was employed in combination with muriatic acid. Given in this form, though powerfully febrifuge, it was found not to produce narcotic effects, not to constipate the bowels, and never to occasion the distressing headache and restlessness which sometimes follow the use of quinia. It proved, moreover, powerfully sudorific. It was given in doses of three grains, three times a day. Dr. O'Shaughnessy was induced to recommend its employment to his medical friends in India, from a knowledge that it had proved effectual in mild agues, in the hands of Dr. Roots and Mr. Jetson in England.*

Codeia was discovered in 1832 by Robiquet in the muriate of morphia prepared according to the process of Gregory. It exists in opium combined like morphia with meconic acid, and is extracted along with that alkali in the preparation of the muriate. (See *Morphia.*) When the solution of the mixed muriates of morphia and codeia is treated with ammonia, the former alkaloid is precipitated, and the codeia, remaining in solution, may be obtained by evaporation and crystallization. It may be purified by treating the crystals with hot ether, which dissolves them, and yields the codeia in colourless crystals by spontaneous evaporation. This alkaline product melts at 300° without decomposition. Guy gives 220° as its point both of fusion and volatilization. (*Pharm. Journ. and Trans.*, Feb. 1868, p. 374.) It is soluble in water, which takes up 1·26 per cent. at 60°, 3·7 at 110°, and 5·9 at 212°. When added in excess to boiling water, the undissolved portion melts and sinks to the bottom, having the appearance of an oil. It is soluble also in alcohol and ether, but insoluble in alkaline solutions. Hence, it may be separated from morphia by a solution of potassa or soda, which dissolves the morphia, and leaves the codeia. It has an alkaline reaction on test paper, and combines with acids to form salts, some of which are crystallizable, particularly the nitrate. Its capacity of saturation is almost identical with that of morphia. According to Robiquet, 1 part of muriatic acid is saturated by 7·837 of codeia, and by 7·88 of morphia. It is distinguishable, however, from the latter principle by the different form of its crystals, which are octohedral, by its solubility in boiling ether, greater solubility in water, and insolubility in alkaline solutions, and by not assuming a red colour with nitric acid, nor a blue one with the salts of sesquioxide of iron. (*Journ. de Pharm.*, xix. 91.) Tincture of galls precipitates from its solutions a tannate of codeia. Crystallized from a watery solution, it contains about 6 per cent. of water, which is driven off at 212°. The crystals obtained from a solution in ether contain no water. Like most of the other organic alkalies, it consists of carbon, hydrogen, nitrogen, and oxygen; its received formula being $C_{35}H_{20}NO_5$, and its combining number consequently 284. According to Dr. Anderson, however, the formula of the anhydrous alkaloid is $C_{36}H_{21}NO_6$, with the addition of two eqs. of water in the hydrate. (*Month. Journ. of Med. Sci.*, May, 1850, p. 492.) Dr. Gregory tried the effects of *nitrate of codeia* upon himself and several of his pupils, and found that, in a dose of three grains or less, it produced no obvious effect, but, in the quantity of from four to six grains, accelerated the pulse, occasioned a sense of heat in the head and face, and gave rise to an agreeable excitement of the spirits like that resulting from intoxicating drinks, which was attended with a sense of itching upon the skin, and, after lasting for several hours, was followed by an unpleasant depression, with nausea and sometimes vomiting. No tendency to sleep was observed, ex-

* The different effects, obtained by different experimenters from narcotina, are readily explicable, should the statements as to the existence of a powerful alkaloid (opiania), which may have been mixed with the narcotina, and of several different modifications of narcotina itself (*page* 638), prove to be correct. (*Note to the tenth edition.*)

cept in the state of depression. In two or three cases the medicine produced a slight purgative effect; but in others it appeared to exercise no peculiar influence on the bowels. Mr. A. F. Haselden considers a grain of codeia as equivalent to half a grain of morphia; and states that two grains cause nausea. On the same authority, the hydrochlorate is more powerful than the pure alkaloid; two grains of it inducing vertigo, nausea, and vomiting. He has found facial and ischiatic neuralgia to yield to it, when all other means had failed. (*Pharm. Journ. and Trans.*, Sept. 1866, p. 156.) M. Barbier, of Amiens, administered codeia *uncombined* in numerous cases, and observed that, in the dose of one or two grains, it acted on the nervous system, and appeared to be directed especially to the great sympathetic; as it relieved painful affections having their origin apparently in disorders of that nerve, while it exerted no influence over pains of the back and extremities supplied by nerves from the spinal marrow. He did not find it to affect the circulation, disturb digestion, or produce constipation. In sufficient quantity, it induced sleep without giving rise, like opium, to signs of cerebral congestion. Dr. Mirandi, of Havana, employed it with advantage in several bad cases of dyspepsia. Dr. Aran, of Paris, considers it one of the most efficient means in our possession for relieving pain, and obtaining calm sleep, inferior to morphia only that it must be given in larger doses, and having the advantage over it that it does not occasion disturbed sleep, disorder of the stomach, constipation, or sweating with cutaneous eruptions. (*Am. Journ. of Med. Sci.*, Jan. 1, 1863, p. 184.) Dr. Garrod, of London, however, has had a different experience, having found it, in large doses, neither anodyne nor soporific. (*Med. Times and Gaz.*, March, 1864, p. 333.) On the whole, there can be little doubt that codeia has a decided action on the animal economy, and is among the principles upon which opium depends for its peculiar powers. It may be given in syrup, in a dose of from half a grain to two grains or more, and M. Aran has found it efficient in the dose of one-third of a grain. Mr. Haselden recommends a syrup containing two grains to the fluidounce, as the most convenient proportion for a division of the dose.

Paramorphia (*thebaina*) is the name given by Pelletier to a principle, discovered by him in the precipitate thrown down from an infusion of opium, treated with milk of lime. The precipitate being washed with water till the liquid came away colourless, and then treated with alcohol, instead of affording morphia to this solvent, as was anticipated, yielded a new alkaline principle, which was obtained separate by evaporating the alcohol, acting on the residue with ether, allowing the ethereal solution to evaporate spontaneously, and then purifying the resulting crystalline mass by dissolving it in an acid, precipitating by ammonia, and recrystallizing by means of alcohol or ether. Pelletier named it paramorphia, from its close analogy in composition with morphia, from which, however, it is quite distinct in properties. It is white, crystallizable in needles, of an acrid and styptic rather than bitter taste, fusible at about 300° (fusible at 210°, volatilizable at 320°, *Guy*), scarcely soluble in water, very soluble in alcohol and ether when cold, and still more so when heated, and capable of combining with the acids, with which it forms salts not crystallizable from their aqueous solution. Alkalies precipitate it from its acid solutions, and, unless in very concentrated solution, do not dissolve it when added in excess. It is not, like morphia, reddened by nitric acid, nor does it become blue with solutions of the salts of sesquioxide of iron. From codeia it differs in never being in large crystals, in not forming crystallizable salts, in being always precipitated from its acid solutions by ammonia, and in not melting in oily drops. From narcotina, which it most resembles, it may be distinguished by its shorter crystals, which want the pearly appearance of those of narcotina, by its different taste, by its much greater solubility in cold alcohol, of which 10 parts will dissolve 1 of this principle, while narcotina requires 100 parts, and by the action of nitric acid, which converts it into a resin-like matter before dissolving it, while the same acid instantly dissolves narcotina. It consists of carbon, hydrogen, nitrogen, and oxygen; its formula being, according to Dr. Anderson, $C_{38}H_{21}NO_6$. (See *Journ. de Pharm.*, 3e sér., xxiv. 233.) The name of *thebain*

was proposed for it by M. Couërbe, who was disposed to give the credit of its discovery to M. Thiboumery, the director of Pelletier's laboratory. Magendie considered it closely analogous, in its effects on the system, to strychnia and brucia, producing tetanic spasms in the dose of a grain.

Papaverina (*papaverin*). The discovery of this alkaloid was announced by Dr. G. Merck. It is crystallizable in needles, fusible at 210° and volatilizable at 310° (*Guy*), insoluble in water, very sparingly soluble in cold alcohol or ether, more soluble in these liquids boiling hot, and deposited by them on cooling. With acids it forms salts, most of which are very sparingly dissolved by water. The muriate crystallizes with extraordinary facility. The alkaloid is readily dissolved by moderately concentrated muriatic acid, from which, on the addition of more acid, the muriate separates, assuming the form of an oily layer at the bottom of the vessel, which is readily converted on standing into a mass of acicular crystals. These crystals are very sparingly soluble in cold water. The muriate yields with bichloride of platinum a yellow precipitate which is insoluble in boiling water or alcohol. Papaverina is prepared by precipitating the aqueous infusion of opium with soda, exhausting the precipitate with alcohol, evaporating the tincture to dryness, treating the residue with a dilute acid, filtering, precipitating by ammonia, dissolving the precipitate in muriatic acid, mixing acetate of soda with the solution, and treating with boiling ether the resulting precipitate. The ethereal solution deposits the papaverina on cooling. A characteristic property of this alkaloid is that its crystals, when moistened with concentrated sulphuric acid, acquire a dark-blue colour. Its formula is $C_{40}H_{21}NO_8$. (*Chem. Gaz.*, March 15, 1850; from *Liebig's Annalen.*) Papaverina has been further investigated by Dr. Thomas Anderson, who confirms the statements of Merck. (*Chem. Gaz.*, Jan. 15, 1855, p. 21.)

Opiania (*opianin*). This was found by Dr. Hinterberger in some supposed narcotina, which had been obtained by Engler, an apothecary of Vienna, from a parcel of Egyptian opium which he was working for morphia. An infusion of the opium was precipitated by ammonia, and the precipitate, having been washed first with water and then with cold alcohol, was dissolved in hot alcohol, and decolorized by animal charcoal. A crystalline mass was thus obtained, consisting apparently of morphia and narcotina. By repeated solutions in hot alcohol and crystallization, the former was separated, remaining in the alcohol, while the supposed narcotina was obtained in crystals. These, upon being examined by Dr. Hinterberger, proved to be a new alkaloid, to which he gave the name of *opianin*. It is in long, colourless, transparent needles, belonging to the prismatic system. When precipitated by ammonia from the solution of the muriate, it is in the form of a soft white powder. It is without smell, and in alcoholic solution has a strong and durable bitter taste. At the temperature of 212° F. it remains unchanged. It is insoluble in water, and requires for solution a large quantity of boiling alcohol, from which it is entirely thrown down, upon cooling, in the state of crystals. In alcoholic solution it has a strong alkaline reaction; and from this solution both opiania itself and its salts are thrown down by alkalies. Concentrated sulphuric acid dissolves without changing it; nitric acid renders it yellow, and, if added to its sulphuric acid solution, blood-red, but after a short time changing to light-yellow. Its formula, according to Hinterberger, is $C_{66}H_{36}N_2O_{21}$. From experiments, it has been inferred to be powerfully narcotic, and to resemble morphia in its action. About one-tenth of a grain of one of these alkaloids was given to a cat, and the same quantity of the other to another cat, with very similar effects. These were decidedly narcotic, and continued for a considerable time, but had ceased at the expiration of 24 hours, without fatal effects. (*Chem. Gaz.*, Dec. 1, 1852, p. 444.)

Narceia or *narcein*, discovered by Pelletier in 1832, is white, in silky acicular crystals, inodorous, of a slightly bitter taste, fusible at 197° F. (170°, and volatilizable at 420°, *Guy*), soluble in 375 parts of cold and 220 of boiling water, soluble also in alcohol, and insoluble in ether. It forms a bluish compound with iodine, the colour of which is destroyed by heat and the alkalies. It is

rendered blue by the action of mineral acids so far diluted as not to decompose it; but does not, like morphia, become blue by the action of the salts of iron, nor red by that of nitric acid. It is dissolved by the acids, but was thought not to neutralize them, and, though at first considered alkaline by Pelletier, was afterwards ranked with indifferent bodies. At present, however, its alkaloid character is admitted, as it unites with sulphuric acid to form a crystallizable sulphate. (*Journ. de Pharm.*, Avril, 1864, p. 367.) It resembles, moreover, the organic alkalies in its constitution, consisting of carbon, hydrogen, nitrogen, and oxygen. Its formula, according to Dr. Anderson, is $C_{46}H_{29}NO_{18}$. Pelletier obtained it in the course of his analysis of opium. Having formed an aqueous extract of opium, he treated it with distilled water, precipitated the morphia by ammonia, concentrated the solution, filtered it, threw down the meconic acid by baryta-water, separated the excess of baryta by carbonate of ammonia, drove off the excess of the ammoniacal salt by heat, evaporated the liquor to the consistence of syrup, set it aside till a pulpy matter formed containing crystals, separated and expressed this pulpy matter, then treated it with alcohol, and concentrated the alcoholic solution. This, on cooling, deposited crystals of narceia, which were easily purified by repeated solution and crystallization. Meconin, which often crystallizes with it, may be separated by the agency of ether. Experiments have been performed with narceia, which go to prove that it closely resembles morphia in its influence on the system, though somewhat weaker; and that, while capable of producing sleep, relieving pain and irritation, alleviating cough, and checking diarrhœa, it is not followed by the unpleasant sensations about the head and other disagreeable symptoms which often attend the action of morphia, is less disposed to constipate, and less stimulant to the circulation. In cases in which morphia disagrees with the patient, or is otherwise contraindicated, narceia may be resorted to for most of the purposes for which the other alkaloid is employed. It may be administered in pill or syrup. From one-third to three-quarters of a grain may be given for a dose, the smaller to relieve cough, the larger to remove pain or produce sleep.*

* Much attention has recently been attracted to narceia, in consequence of the valuable properties ascribed to it by M. Claude Bernard, as the result of his experimental researches into the physiological properties of the several opium alkaloids respectively. According to M. Bernard, narceia, in its operation on the lower animals, is decidedly soporific, in this respect resembling morphia and codeia, being more energetic than either, though without the deep torpor produced by the former. Bernard, however, was not the first to experiment with narceia. Not long after its discovery, Magendie injected 10 centigrammes (about 1·5 grains) of it, several times into the jugular vein of dogs, without observing any special action. (*Ann. de Thérap.*, 1865, p. 25.) So early as 1852, M. Lecomte demonstrated its soporific effect, having repeated Magendie's experiment, with very different results. Ten centigrammes dissolved in ten grammes of distilled water were injected into the jugular vein of a large dog. The animal was put into a calm sleep with snoring, yet retained sensibility so far as to feel the presence of insects upon the skin; and it was noticed that, while the anterior limbs had lost neither sensibility nor mobility, the posterior had obviously suffered some diminution of these properties, showing that the medicine, in its action on the spinal marrow, more especially affected the lumbar region. (*Ibid.*, p. 27.) Some years later, similar experiments were performed by MM. Debout and Béhier, confirmatory of the results obtained by M. Lecomte and M. Bernard. But they were extended also to the human subject, both in health and disease, and always with similar results.

M. Debout tried on himself a syrup of narceia, each tablespoonful of which contained a centigramme (0·15 gr.), taking a tablespoonful at first twice a day, gradually increased to seven a day, and continued with the latter quantity for ten days. The soporific effect was experienced when the evening dose amounted to 3 centigrammes (nearly half a grain); and the sleep was afterwards deeper in proportion to the increase of the dose. The sleep was always calm, never attended with painful dreams, and was interrupted momentarily by the least noise; nor was it followed in the morning by that heaviness of the head often noticed as the result of morphia. The only inconvenience experienced was a rather obstinate constipation during the continuance of the experiment. Nor was the action pronounced upon the secretory function; although, from a dose of 7 centigrammes (about a grain), some hebetude of the bladder was experienced, which might be ascribed to the influence upon the lower spinal marrow, as observed by M. Lecomte. No itching of the surface, no trouble of sight or hearing, were noticed; the narcotic influence of the medicine being

Pseudomorphia was discovered by Pelletier more than thirty years since; but, as it exists in small quantities, and was thought to be only an occasional ingredient in opium, little attention has been paid to it. An interesting fact, however, in relation to it, and one of some toxicological importance, is that it

limited to its soporific action. It was, however, found to exercise the same calming influence over bronchial irritation, as in the relief of cough. No effect on the respiration or pulse was noticed. The general conclusions drawn from these experiments were as follows. The calming and soporific effects of narceia are superior to those of codeia, and almost equal those of morphia, over which it has the advantage that it operates without causing cerebral congestion, and consequently that the sleep produced by it is lighter, and never attended with painful dreams. Narceia, moreover, is less apt than morphia to disturb the digestive organs; causing nausea and vomiting less frequently, and constipation less intense. The greatest inconvenience from it is that, when it exceeds the quantity of 5 centigrammes (about three-quarters of a grain), it is liable to bring on difficulty of discharging the urine, from a partially paralyzing action on the bladder.

Besides these physiological investigations, narceia has been submitted also to therapeutic trials, with results corresponding with its ascertained influence on the functions. M. Béhier has found it to quiet cough, diminish expectoration in consumptive patients, check diarrhœa, relieve pain, cause sleep, quiet restlessness, and to produce all these effects whether given internally or by subcutaneous injection. Sometimes, however, it caused vomiting, and sometimes suspended the emission of urine, without modifying the desire to micturate. (*Ibid.*, pp. 23–47.)

M. Liné, formerly resident physician of one of the French hospitals, after a series of observations in a ward of the hospital, gives the following conclusions, which are in close conformity with those of his predecessors. Narceia exceeds all the opium alkaloids in soporific power; neither morphia nor codeia, as a general rule, producing either so protracted or so profound a sleep. While thus energetic as a soporific, it gives rise only in a very slight degree to those secondary effects of opium which so often interfere with its administration, such as excessive perspiration, headache, a sense of heaviness in the head, nausea, vomiting, &c. It does not constipate like opium, and, according to M. Liné, even induces diarrhœa in large doses; a point, however, in which his experience differs from that of M. Debout. It relieves pain, and very generally acts with a more or less paralyzing effect on the urinary excretory function. (*Druggists' Circular*, June, 1866; from *Gazette des Hôpitaux.*)

To the foregoing testimony must be added that of Dr. Eulenburg. According to this practitioner, narceia, while acting as a narcotic, causes at first a diminished frequency and volume of the pulse, followed after some time by acceleration. The pulse rarely increases during its use more than 12 or 15 beats in a minute. Upon the cutaneous nerves it acts like other narcotics. The repetition of internal doses often produces one or two stools, and sometimes even a diarrhœa, conformably with the observation of M. Liné. It appears, however, to retard the occurrence of the menses. Subcutaneously administered, it produces none of the muscular action which follows the injection of morphia. For the relief of irritation, and as a soporific, it is preferable to every other medicine. It is, indeed, indicated, independently of simple idiopathic neuralgia, in all cases where pain is the prominent symptom, such as affections of the joints, phlegmon, painful ocular diseases, orchitis, cystitis, cyrrhosis of the liver, wounds, and after painful operations. In all these cases, employed internally or externally, in the doses recommended by Dr. Eulenburg, it quickly relieves the pain, and often produces a sleep of four, five, or even nine hours; a sleep sweet, tranquil, uninterrupted, and with a peaceful awakening; always without disordered action or poisonous effect. In many cases of disease morphia can scarcely be used in consequence of its various unpleasant effects, primary or secondary; and to these narceia is admirably adapted, as it produces the good effects, so far as relates to the relief of pain and irritation and the production of sleep, without the noxious and disagreeable. The dose employed by Dr. Eulenburg for producing sleep and relieving pain is from $\frac{1}{6}$ to $\frac{1}{2}$ a grain internally, and from $\frac{1}{8}$ to $\frac{1}{4}$ by the hypodermic method. In sick headache, $\frac{1}{8}$ of a grain, followed shortly afterwards by one-ninth of a grain, taken at the beginning, produces a sleep which continues several hours, and from which the patient awakes in full health. (*Ann. de Thérap.*, 1867, pp. 6–9.)

Of the numerous communications upon the effects and uses of narceia, the author has met, with but a single exception, with none which was not commendatory; and in all there is so close an agreement as to the peculiar effects of the medicine, that there is scarcely room for doubt on the subject. The exception referred to is that presented in the report of Dr. Da Costa as to the effects of the medicine in the wards of the Pennsylvania Hospital. (See *Reports of the Penn. Hospital*, 1868, p. 177.) The effects in this instance were such as failed altogether to support the highly flattering statements heretofore made on the subject of narceia; and if the medicine employed by Dr. Da Costa was really narceia, tolerably pure, his experience must throw a strong doubt upon the favourable statements made by others. Only further observation and experience can determine the question. (*Note to the thirteenth edition.*)

possesses two properties considered characteristic of morphia, those namely of being reddened by nitric acid, and of striking a blue colour with the salts of iron, and yet is without any poisonous influence upon the animal economy. (*Journ. de Pharm.*, xxi. 575.) Hesse has recently investigated the subject, with the following results. He found that it accompanies morphia procured by Gregory's method, and may be separated from that alkaloid by adding ammonia in excess to an alcoholic solution containing both. The morphia is precipitated, and pseudomorphia, remaining in solution, may be obtained by evaporating the mother-liquid. It is tasteless, insoluble in water, alcohol, ether, chloroform, and dilute sulphuric acid, but easily soluble in solution of potassa, soda, and lime, and in alcoholic solution of ammonia, though sparingly in a watery solution of the last-mentioned alkali. It does not neutralize muriatic acid, dissolves in concentrated sulphuric acid with the production of an olive-green colour, in concentrated nitric acid with an intense orange-red, and in solution of sesquichloride of iron with a blue colour. At 248° F. it loses two eqs. of water of crystallization, and at higher temperatures is decomposed without melting. Its composition is represented by the formula $C_{24}H_{19}NO_8$. It forms sparingly soluble salts with sulphuric, nitric, oxalic, and tartaric acids, and a crystalline deposit, very slightly soluble in muriatic acid, with solution of corrosive sublimate. (*Chem. News*, April 12, 1867, p. 188.)*

* *Cryptopia.* The discovery of this alkaloid was announced by Messrs. T. and H. Smith, of Edinburgh, in a communication to the *Pharmaceutical Journal and Transactions* for April, 1867 (p. 595); but it has yet been for too short a time before the pharmaceutical public to be admitted among the undoubted constituents of opium. A notice of it is, therefore, introduced here in the form of a note. The Messrs. Smith obtained it from the weak alcoholic washings of crude morphia after precipitation, by first neutralizing the liquid with dilute sulphuric acid, and then, after recovering the alcohol by distillation, and washing out the still copiously with hot water, by precipitating the mixed liquor of the still and the washings by milk of lime in large excess. The liquid is then filtered off, and the pitch-like precipitate, having been thoroughly washed, is boiled with alcohol in large quantity, the solution filtered, and the alcohol distilled off. The pitchy substance which remains in the retort, and which consists mainly of thebaina, is separated from the supernatant watery liquid, and heated to ebullition with enough alcohol to dissolve it. The solution, having been set aside, will be found in a day to have set into a mass of crystals, which consist of crystallized thebaina. This mass is now strongly pressed in a cloth, and the residuary cake powdered and dissolved in dilute muriatic acid; care being taken that the acid be not in excess. The filtered liquid is evaporated and crystallized, and the process of evaporation and crystallization repeated, so as to separate all the muriate of thebaina. If now the mother-waters be set aside, the muriate of cryptopia will in the course of some weeks crystallize out of them, but mixed with crystallized muriate of thebaina; and the separation of the two is extremely difficult. But as the crystals of the two alkaloids are very different, those of thebaina being hard and strong, those of cryptopia soft and generally tufted, by careful management, and by repeating the crystallization many times, so as to get rid of most of the thebaina, the muriate of cryptopia may be seen forming on the surface of the harder salt in the solution. The mother-liquors being now poured off, and allowed to evaporate spontaneously, the whole at length sets into a soft mass, which, being pressed in a cloth, is found to consist of almost pure muriate of cryptopia. But the practical reader who wishes to carry the process into effect is referred to the paper of the Messrs. Smith for details, without which he might not be able to succeed in his essays. To obtain the pure alkaloid, it is to be precipitated from the solution of the muriate by ammonia, then washed, dried, and finally washed with ether or alcohol, which readily dissolves thebaina, but has little effect on cryptopia. It may be got in a crystallized state by boiling it with a large quantity of alcohol, which, on cooling, will slowly deposit the alkaloid in crystals. The quantity of cryptopia obtained from opium is extremely small; and it must, I think, strike the reader of this process as highly probable, that it is rather a product formed out of thebaina than a proper educt of the drug.

Cryptopia is without colour or smell; and its salts, though at first bitter to the taste, afterward cause a sense of coolness in the mouth, like that produced by peppermint. It melts at about 400° F., and, heated to redness, is decomposed, blackening and giving forth watery vapours, but without properly subliming. According to Guy, it melts and sublimes at the same temperature of 350°. It is insoluble in water, quite insoluble in ether, and very sparingly soluble in alcohol, requiring 1265 parts of that liquid when cold to dissolve it. Chloroform dissolves it almost as freely as narcotina. Oil of turpentine and benzole do not appear to dissolve it. It has very strong alkaline powers, and forms crystallizable salts with the acids, which are distinguishable from all the other salts of the

Meconin, the existence of which was announced in 1832 by M. Couërbe, is identical with a substance discovered several years previously by M. Dublanc, jun., but of which no account was published. It is perfectly white, in the form of acicular crystals, soluble in about 265 parts of cold and 18 of boiling water, very soluble in ether, alcohol, and the essential oils, fusible at 195°, volatilizable without change (fusible at 120°, sublimable at 180°, *Guy*), and possessed of a degree of acrimony which favours the supposition that it may not be without action upon the system. It is neither acid nor alkaline, and contains no nitrogen. Meconin is obtained by precipitating the aqueous infusion of opium with ammonia, washing the precipitate with water until the latter nearly ceases to acquire colour, mixing the watery fluids, evaporating them to the consistence of molasses, setting them aside for two or three weeks, during which a mass of granular crystals is formed, then decanting the liquid, expressing the mass, and drying it with a gentle heat. The meconin may be separated from the mass by treating it with boiling alcohol of 36° Baumé, evaporating so as to obtain crystals, dissolving these in boiling water with animal charcoal, filtering the liquid while hot, and subjecting the crystals formed upon the cooling of the solution to the action of ether, which dissolves the meconin, and yields it in a state of purity by spontaneous evaporation. (*Journ. de Pharm.*, Dec. 1832.)

Porphyroxin may be obtained, according to Merck, by treating powdered opium, previously exhausted by boiling ether, and then made into a pulp by means of water, with carbonate of potassa, agitating it with ether, evaporating the ethereal solution, dissolving the residue in dilute muriatic acid, and precipitating with ammonia. Paramorphia and porphyroxin are thus obtained together. These are to be dissolved in ether, which, by spontaneous evaporation, deposits the former in crystals, and the latter in the form of resin. The porphyroxin is separated by the cautious use of alcohol, and obtained by the evaporation of the alcoholic solution. It is neuter, crystallizable in shining needles, insoluble in water, soluble in alcohol and ether, and characterized by the property of assuming a purple-red or rose colour, when heated in dilute muriatic acid. (*Journ. de Pharm.*, 3e sér., xiv. 188.)

Meconic acid is in white crystalline scales, of a sour taste followed by bitterness, fusible and volatilizable by heat, soluble in four parts of boiling water, soluble also in cold water and alcohol, with the property of reddening vegetable blues, and forming salts. Its compounds with the earths and heavy metallic oxides are generally insoluble in water. Its characteristic properties are, that it produces a blood-red colour with the salts of sesquioxide of iron, a green precipitate with a weak solution of ammoniated sulphate of copper, and white precipitates soluble in nitric acid, with acetate of lead, nitrate of silver, and chloride of barium. It is obtained by macerating opium in water, filtering the infusion, and adding a solution of chloride of calcium. Meconate and sulphate of lime are precipitated. The precipitate, having been washed with hot water and with alcohol, is treated with dilute muriatic acid at 180°. The meconate of lime is taken up, and upon the cooling of the liquid, bimeconate of lime is deposited. This is dissolved in warm concentrated muriatic acid, which deposits pure meconic acid when it cools. It may be freed from colouring matter by neutralizing it with potassa, decomposing the crystallized meconate thus obtained by muriatic acid, and again crystallizing. Meconic acid has little or no

opium alkaloids by a strong tendency to gelatinize. If the muriate be dissolved in about 30 parts of hot water, and set aside, instead of crystallizing, it forms a jelly closely resembling that of pure gelatin. From all the constituents of opium, except the stronger alkaloids, morphia, codeia, and thebaina, it is distinguished by its strong alkaline properties, as it neutralizes the strongest acids. From morphia it is distinguished by its very sparing solubility in alcohol, and from codeia and thebaina by its total insolubility in ether. It differs also in the effect of strong sulphuric acid, which produces a blue colour with the minutest quantity of cryptopia, a blood-red with thebaina, and none with morphia or codeia. The tendency of its salts to gelatinize is another distinguishing property of the cryptopia. The formula of the alkaloid, admitting the eqs. of C to be 12 and of O 16, is $C_{23}H_{25}NO_5$. (*Pharm. Journ. and Trans.*, April, 1867, p. 595, and June, 1867, p. 716.)—*Note to the thirteenth edition.*

action on the system, and is not used separately in medicine; but its natural relation to morphia requires that it should be understood.

Thebolactic acid, which was discovered by the Messrs. T. and H. Smith, of Edinburgh, appears to be a constant ingredient in opium. These chemists were led to search for it by the consideration that the quantity of meconic acid present is insufficient to saturate the whole of the morphia and other bases, which must, therefore, be neutralized by some other acid. They obtained it from the impure mother-liquid of morphia, after all the alkaloids had been thrown down by the addition of an alkali, by concentrating the liquors to a thick consistence, adding alcohol largely, filtering, precipitating all basic matter by sulphuric acid, filtering again, carefully neutralizing by milk of lime, distilling to recover the alcohol, and finally evaporating the residuary contents of the still to a syrupy consistence. After standing for about a week, the syrupy liquid will be seen to have set into a crystalline mass of thebolactate of lime. This, being purified by repeated solution and crystallization and by animal charcoal, is decomposed by adding the equivalent quantity of sulphuric acid, and separating the liberated thebolactic acid by means of alcohol. Stenhouse has shown that the new acid has the composition of lactic acid; but, according to Dr. Anderson, it is only isomeric and not identical with that acid. Its name implies the admission of its close relation to lactic acid, of which it may be regarded as a variety. The ready crystallization of its salt with lime is a characteristic property. (*Pharm. Journ.*, July, 1865, p. 50)

Incompatibles. All the substances which produce precipitates with opium do not necessarily affect its medical virtues; but the *alkalies*, and all vegetable infusions containing *tannic* and *gallic acids*, are strictly incompatible; the former separating and precipitating the active principle, the latter forming with it an insoluble compound.

The proportion of morphia which any particular specimen of opium will furnish, may be considered as the best test of its value, except that of actual trial upon the system. Good opium should yield 10 or 12 per cent. of the impure morphia precipitated from the infusion by ammonia with alcohol, according to the process of the U. S. Pharmacopœia. (See *Morphia.*) The U. S. Pharmacopœia directs that it should yield at least 7 per cent. of the pure alkaloid by the officinal process. The Br. Pharmacopœia requires at least 6 per cent.

M. Guilliermond gives the following mode of estimating the strength of opium, as tested by the amount of morphia to be obtained from it. Take 15 parts of opium, cut it in pieces, rub it up with 60 parts of alcohol of 71°, drain the mixture on linen and express, treat the residue with 40 parts of alcohol also of 71°, unite the tinctures in a vessel with a large mouth into which 4 parts of solution of ammonia (22° Cartier) have been introduced, and allow the mixture to stand 12 hours. The crystals which form are to be put upon linen, washed repeatedly with water to separate the meconate of ammonia, and then introduced into a small vessel of water. The crystals of narcotina, being very light, continue suspended in the water, and may be decanted along with it, while those of morphia remaining at the bottom, may be collected and weighed. Good opium, treated in this way, will yield for the fifteen parts employed from 1·25 to 1·75 parts of the crystals of morphia. (*Journ. de Pharm.*, xvi. 18.)*

* As the morphia obtained in the above process is not quite free from narcotina, M. De Vry proposes the following modification. The mixture of morphia and narcotina, precipitated from the alcoholic solution by ammonia, after being washed, is to be heated with a slight excess of sulphate of copper dissolved in pure water. The narcotina has no action on the sulphate of copper, which is decomposed by the morphia, producing sulphate of morphia and tribasic sulphate of copper. The latter and the narcotina remain undissolved, and a solution is obtained containing sulphate of morphia with a little sulphate of copper. This, having been filtered, is treated first with sulphuretted hydrogen which precipitates the copper, and afterwards with ammonia which throws down the morphia. (*Pharm. Journ.*, x. 77.)

M. Fordos' method of estimating the proportion of morphia. Practical difficulties having been experienced in the application of M. Guilliermond's method, though much better than any plan previously proposed, the Belgic Academy of Medicine made the offer of a prize,

Tests of Opium. It is sometimes highly important to be able to ascertain the presence or absence of opium in any suspected mixture. As meconic acid and

which seems to have elicited the following process, considered by M. Fordos as the easiest of execution, and most accurate in its results. Macerate in 60 cubic centimetres of water 15 grammes of opium, cut into fine slices, agitating occasionally. After 24 hours, or sooner if there is any urgency, pour the mixture into a mortar, and divide the opium thoroughly by the pestle. Then pour the whole on a small filter, and, after the liquid has passed, wash the filter with 15 cubic centimetres of water with which the mortar and pestle have been thoroughly cleansed. Repeat the washing a second and a third time, using each time 10 cubic centimetres of water. The opium is thus sufficiently exhausted. One-third of the mixed liquids is taken in order to determine the quantity of ammonia necessary to precipitate the morphia. To this add the ammonia drop by drop till the liquor offers a slight ammoniacal odour, and then immediately cease. Note the quantity of ammonia consumed. Operate then on the residuary two-thirds of the liquid, representing 10 grammes of opium, with the view of ascertaining the proportion of morphia. Add an equal volume of alcohol of 85°, and twice the quantity of ammonia consumed in the previous operation. A slight excess of ammonia is requisite to separate all the morphia. Agitate the liquor, and allow it to stand in a bottle well stopped. Narcotina is soon deposited in fine needles but slightly coloured, and morphia in prisms larger and somewhat more coloured. After two or three days shake the bottle, and then allow it to rest for some hours, in order to give time for the deposition of the whole of the morphia. Collect the crystals on a small filter, and wash them with 15 or 20 cubic centimetres of weak alcohol, of only 40 or 50 to the 100. This washing removes the adhering mother-water, and frees the crystals from the colouring matter. There remain crystals of morphia little coloured, and white crystals of narcotina. Allow them to dry on the same funnel. Then pour on the filter from 10 to 15 cubic centimetres of pure sulphuric ether; and afterwards, at two or three times, from 10 to 15 cubic centimetres of chloroform. The crystals of narcotina are instantly dissolved in the chloroform, and carried off with it; and the morphia remains untouched. Lastly wash the filter with 15 cubic centimetres of ether, to remove the last traces of chloroform and narcotina. Dry the filter, and weigh the crystals of morphia, which may be very easily detached. To verify the result, ascertain that the crystals are entirely soluble in a solution of caustic potassa. The weight will represent the quantity of morphia in 10 grammes of the opium. We have been particular in presenting each step of the process precisely, as much depends upon a proper manipulation. The French weights and measures have been given for the sake of accuracy; but the operator may easily translate them into the equivalent weights and measures in use with us by consulting the table in the Appendix; or he can use any other convenient weight and measure, taking care to observe the same proportions. (*Journ. de Pharm.*, 3e sér., xxxii. 101.)

In the *Am. Journ. of Pharm.* for Sept. 1863 (p. 385) is an interesting and valuable article on the assay of opium by Prof. F. F. Mayer, to which, for want of space, we must content ourselves with referring the reader. It is highly important that the apothecary should be able to determine the strength of his opium, and never to use any in his officinal operations, excepting for the preparation of morphia or its salts, which does not come up at least to the percentage required by our officinal standard. Sometimes it may happen that the opium is much stronger in morphia than that in ordinary use, and the consequence may be that an unexpected violence of operation may result. Hence it has been proposed in France to adopt some standard, and by mixing parcels of different strengths in proper proportion to get an opium which shall always be the same. In a paper on opium in the *Am. Journ. of Pharm.* (March, 1860, p. 115), Dr. Squibb has treated on this subject, and proposes a preparation which, whatever may be the strength of the opium used, shall always have a fixed value. Could such a preparation, based on sound principles, and of sufficiently easy execution, receive the sanction of our national code, it would certainly be of great practical importance. (*Notes to the twelfth edition.*)

M. A. Guilliermond, the son, believes that by giving more precision to his father's method, identical results may be obtained; and with this view gives the following modification. Take 15 grammes of opium, and rub it well in a mortar with 110 grammes of alcohol at 70 per cent. (120 cubic centimetres). After half an hour of trituration, when the disintegration is complete, ascertain the weight of the mixture, which ought to be 125 grammes, and, if not, add enough alcohol to make it so; then shake thoroughly, that the tincture may be uniformly saturated; filter into a little bottle with a large mouth 80 cubic centimetres, which should represent exactly two-thirds of the opium used, or 10 grammes; cause 2 grammes of liquid ammonia (22° B.), by means of a small glass tube drawn to a point at the lower end, to reach without disturbing the liquid at the bottom of the vessel; withdraw the tube by degrees, without agitating the liquid; cork the bottle so as to prevent evaporation. At the end of 36 hours the morphia will have separated in gravelly crystals, more or less rusty-coloured, but well formed. If it be accompanied with narcotine, this will crystallize in white shining needles, which in most cases can be separated by washing with water. The precipitate, washed with boiling water, will represent, in decimal relation, the proportion of morphia to the opium. By proceed-

morphia have been found only in the products of the poppy, if either or both of them be shown to exist in any substance, very strong evidence will be afforded of the presence of opium. The test should, therefore, be applied in reference to the detection of these two principles. If an aqueous infusion of the substance examined yields a red colour with the tincture of chloride of iron, there is presumptive evidence of the presence of meconic acid. Greater certainty may be obtained by the following process. Add in excess to the filtered liquor a solution of acetate of lead. If opium be present, there will be a precipitate of meconate of lead, and the acetates of morphia and lead will remain in solution. The precipitate is then to be suspended in water, and decomposed, either by adding a little dilute sulphuric acid, which forms sulphate of lead and leaves the meconic acid in solution, or by passing through it a stream of sulphuretted hydrogen, removing by filtration the precipitated sulphuret of lead, and heating the clear liquor so as to drive off the sulphuretted hydrogen. With the clear liquor thus obtained, if it contain meconic acid, the tincture of chloride of iron will produce a striking red colour, ammoniated sulphate of copper a green precipitate, and acetate of lead, nitrate of silver, and chloride of barium, white precipitates soluble in nitric acid. Sulphocyanide of potassium, which, according to Dr. Wright, is an invariable constituent of saliva (*Simon's Chemistry*, ii. 6), produces a red colour with the salts of sesquioxide of iron, resembling that produced by meconic acid; but, according to Mr. Everitt, this colour is entirely and at once destroyed by a solution of corrosive sublimate, which has no effect on the red colour of the meconate of iron. (See *Am. Journ. of Pharm.*, xii. 88.) On the contrary, chloride of gold reddens a solution of hydrosulphocyanic acid or a sulphocyanide, but not of meconic acid. Pereira says the acetates also redden the salts of sesquioxide of iron, but do not afford the results just mentioned with acetate of lead and chloride of barium. To test the presence of morphia, the liquid from which the meconate of lead has been precipitated, and which may be supposed to contain the acetates of morphia and lead, must be freed from the lead by a stream of sulphuretted hydrogen, and then from the sulphuretted hydrogen by heat; after which, the following reagents may be applied:—viz. 1. nitric acid, which colours the morphia red; 2. iodic acid, which is decomposed by the morphia with the extrication of iodine, which colours the liquid reddish-brown, and, if starch is present, unites with it to form a blue compound; 3. solution of ammonia, which, if carefully added so as not to be in excess, throws down a precipitate of morphia soluble in a great excess of that alkali or of potassa; and 4. tannic acid, which precipitates tannate of morphia. If the precipitate thrown down by ammonia afford a deep-red colour becoming yellow with nitric acid, and a blue colour with sesquichloride of iron, the proofs may be considered as complete.*

ing on this plan, results will be obtained identical among themselves; but it is very certain that the morphia deposited does not exactly represent that contained in the opium, since the alcohol retains a portion; but it expresses the proportion relatively and sufficiently. (*Journ. de Pharm. et de Chim.*, Août, 1867, p. 102.)

M. Roussille proposes to modify Guilliermond's process, so as to shorten it without impairing its efficiency. The 15 grammes of opium are treated with 25 grammes of boiling water to complete disintegration; 60 grammes of boiling alcohol of 40° are added; the mixture is digested for an hour, and strained through linen; and the residue is again treated with 10 grammes of water and 60 grammes of alcohol, as before. The residue is now treated with 50 grammes of boiling absolute alcohol. All the liquids, mixed together and cooled, are carefully filtered, evaporated to one-third, and again filtered after cooling. Then the morphia is precipitated with 10 grammes of solution of ammonia (22° B. of the Fr. Codex); and the liquid is evaporated over sulphuric acid. At the end of three days the crystals are collected, and washed with ether and with water. The same results are given as by Guilliermond's process, which occupies more than five days, while this requires only three. (*Chem. News*, Oct. 5, 1866.)

Another modification is proposed by M. Fleury, in which oxalate of ammonia is added to the water with which the opium is first treated, in order to get rid of the meconate of lime, the presence of which embarrasses the process. For details the reader is referred to the *Journ. de Pharm. et de Chim.* (Août, 1867, p. 99).—*Notes to the thirteenth edition.*

* Merck has proposed a test of opium, founded on the property, which characterizes

Though opium is little injured by time if well kept, yet it does undergo spontaneous change, and M. Guibourt found less morphia in a specimen which had been in his possession nearly twenty years than it had yielded in its recent state. There was also more colouring matter. (*Ann. de Thérap.*, A. D. 1863, p. 5.)

Among the adulterations of opium, starch has been detected in a specimen examined by Mr. J. T. King. The drug was unduly brittle, and evidences of starch were afforded both by the microscope and by iodine. From the size and form of the granules, Mr. King inferred that the starch was that of the bean. (*Am. Journ. of Pharm.*, Jan. 1869, p. 1.) The probability is that powdered beans were the substance used.

Medical Properties and Uses. Opium is a stimulant narcotic. Taken by a healthy person in a moderate dose, it increases the force, fulness, and frequency of the pulse, augments the temperature of the skin, invigorates the muscular system, quickens the senses, animates the spirits, and gives new energy to the intellectual faculties. Its operation, while thus extending to all parts of the system, is directed with peculiar force to the brain, the functions of which it excites sometimes even to intoxication or delirium. In a short time this excitation subsides; a calmness of the corporeal actions, and a delightful placidity of mind succeed; and the individual, insensible to painful impressions, forgetting all sources of care and anxiety, submits himself to a current of undefined and unconnected, but pleasing fancies; and is conscious of no other feeling than that of a quiet and vague enjoyment. At the end of half an hour or an hour from the administration of the narcotic, all consciousness is lost in sleep. The soporific effect, after having continued for eight or ten hours, goes off, and is generally succeeded by more or less nausea, headache, tremors, and other symptoms of diminished or irregular nervous action, which soon yield to the recuperative energies of the system; and, unless the dose is frequently repeated, and the powers of nature worn out by over-excitement, no injurious consequences ultimately result. Such is the obvious operation of opium when moderately taken; but other effects, very important in a remedial point of view, are also experienced. All the secretions, with the exception of that from the skin, are either suspended or diminished; the peristaltic motion of the bowels is lessened; pain and inordinate muscular contraction, if present, are allayed; and general nervous irritation is composed, if not entirely relieved.

In doses insufficient to produce the full soporific effect, the stimulant influence upon the mental functions continues longer, and the subsequent calming effect is sustained for hours; sleep being not unfrequently prevented, or rendered so light and dreamy that, upon awaking, the patient will scarcely admit that he has slept at all. From large doses the period of excitement and exhilaration is shorter, the soporific and anodyne effects are more intense and of longer duration, and the succeeding symptoms of debility are more obvious and alarming.

From quantities sufficient to destroy life, after a brief excitement, the pulse is reduced in frequency though not in force, muscular strength is diminished, and feelings of languor and drowsiness supervene, which soon eventuate in a deep apoplectic sleep. A stertorous respiration; a dark suffusion of the countenance; a full, slow, and laboring pulse; an almost total insensibility to external impressions; and, when a moment of consciousness is obtained by violent agitation or irritating applications, a confused state of intellect, and an irresistible

porphyroxin, of assuming a red colour when heated in dilute muriatic acid. The suspected liquid is first to be carefully evaporated, a few drops of solution of potassa are to be added, and the mixture agitated with ether. The ethereal solution being filtered off, a slip of unsized paper is to be dipped into it and dried; and the moistening and drying should be repeated several times. The paper thus prepared is to be moistened with dilute muriatic acid, and then exposed to the vapour of boiling water. If it become reddened, opium may be inferred to exist in the liquid tested. Heusler states that this test is not applicable to the aqueous solution or extract of opium, because porphyroxin is insoluble in water; but Mr. Robertson, of Rotterdam, has found it to succeed with the watery extract, and infers that the porphyroxin is so combined in opium as to render it in some measure soluble. (*Journ. de Pharm.*, 3e sér., xxii. 190.)—*Note to the tenth edition.*

disposition to sink back into comatose sleep, are symptoms which, for the first few hours, attend the operation of the poison. Though not signs of an elevated condition of the bodily powers, neither do they imply a state of pure, unmixed debility. The pulse is, indeed, slow; but it is often so full and strong as even to suggest the use of the lancet. In the space, however, of a few hours, varying according to the quantity of the narcotic taken, and the powers of the patient's constitution, a condition of genuine debility ensues; and this condition will be hastened in point of time, though it will be more under the control of remedies, if the opium be evacuated from the stomach. Called to an individual labouring under the influence of a fatal dose of opium, at a period from six to eight hours after it has been swallowed, the practitioner will generally find him with a cool, clammy skin; cold extremities; a pallid countenance; a feeble, thread-like, scarcely perceptible pulse; a slow, interrupted, almost gasping respiration; and a torpor little short of absolute, death-like insensibility. Death soon follows, unless relief is afforded.

No appearances are revealed by the dissection of those who have died of the immediate effects of opium, which can be considered as affording satisfactory evidence of its mode of operation. The redness occasionally observed in the mucous membrane of the stomach is not constantly present, and is ascribable as much to the irritating effect of remedies prescribed, or to the spirituous vehicle of the opiate, as to the action of the poison itself. Such at least is the inference drawn by Nysten from his experiments and observations; and Orfila states that the stomachs of dogs which he had killed by opium, internally administered, did not present the slightest vestige of inflammation. The force of the medicine is directed to the cerebral and nervous functions; and death is produced by a suspension of respiration, arising from the want of due influence from the brain. The section of the par vagum, on both sides, has not been found to prevent or retard the death of animals to which large doses of opium have been given, nor even materially to modify its narcotic effects. (*Nysten, quoted by Orfila.*) It would seem, therefore, that the active principle is conveyed into the circulation, and operates upon the brain, and probably upon the nervous system at large, by immediate contact. It is an error to attribute the anodyne, sedative, and soporific effects of the medicine to the previous excitement. They are, as much as this very excitement, the direct results of its action upon the brain. It is in the state of exhaustion and collapse which ensue after the peculiar influence of the opium has ceased, that we are to look for an illustration of that principle of the system, by which any great exaltation of its functions above the natural standard is followed by a corresponding depression. We may be permitted to advance the conjecture, that the excitement which almost immediately supervenes upon the internal use of opium, may be in some degree produced by means of nervous communication; while the succeeding narcotic effects are attributable to its absorption and entrance into the circulation; and the ultimate prostration of all the powers of the system is a necessary consequence of the previous agitation of the various organs.

On some individuals opium produces peculiar effects, totally differing from the ordinary results of its operation. In very small quantities it occasionally gives rise to excessive sickness and vomiting, and even spasm of the stomach; in other cases it produces restlessness, headache, and delirium; and we have known it, even in large doses, to occasion obstinate wakefulness. The headache, want of appetite, tremors, &c., which usually follow, in a slight degree, its narcotic operation, are uniformly experienced by some individuals to such an extent as to render the use of the medicine very inconvenient. It is possible that some of these disagreeable effects may arise not from the meconate of morphia contained in the opium, but from some other of its ingredients; and those which do result from the meconate may not be produced by other salts of morphia. It has, indeed, been found that the operation of opium may often be favourably modified by changing the state of combination in which its active principle naturally exists. Dissolved in vinegar or lemon juice, it had been known to act

in some instances more pleasantly and effectually than in substance or tincture, long before physicians had learned to explain the fact by referring it to the production of an acetate or citrate of morphia. When upon the subject of morphia, we shall take occasion to treat of the medical properties of this principle in its various combinations.

An occasional effect of opium, which has not yet been alluded to, is a disagreeable itching or sense of pricking in the skin, sometimes attended with a species of miliary eruption. We have found the effect to result equally from all the officinal preparations of this narcotic.

The general operation of opium may be obtained by injecting it into the rectum, or applying it to the surface of the body, especially upon a part denuded of the cuticle It has appeared to us, when thus applied, to produce less general excitement, in proportion to its other effects, than when administered by the mouth; but we do not make the statement with entire confidence. It is said that, when introduced into the cellular membrane, it acts with great energy; and, when thrown into the cavity of the peritoneum, speedily produces convulsions and death. Injected into the cavity of the heart, it impairs or altogether destroys the powers of that organ.

The local effects of opium are similar in character to those which follow its general operation. An increased action of the part is first observable; then a diminution of its sensibility and contractility; and the latter effect is more speedy, more intense, and of longer continuance, the larger the quantity applied.

In all parts of the world, opium is habitually employed by many with a view to its exhilarating and anodyne influence. This is particularly the case among the Mahomedans and Hindoos, who find in this narcotic the most pleasing substitute for alcoholic drinks, which are interdicted by their religion. In India, Persia, and Turkey, it is consumed in immense quantities; and many nations of the East smoke opium as those of the West smoke tobacco. This is not the place to speak of the fearful effects of such a practice upon both the intellectual and bodily faculties.

The use of opium as a medicine can be clearly traced back to Diagoras, who was nearly contemporary with Hippocrates; and it was probably employed before his time. It is at present more frequently prescribed than perhaps any other article of the materia medica. Its extensive applicability to the cure of disease will be rendered evident by a view of the indications which it is calculated to fulfil. 1. It is excitant in its primary action. In low or typhoid complaints, requiring a supporting treatment, it exalts the action of the arterial and nervous systems, and, in moderate doses frequently repeated, may be employed with advantage in conjunction or alternation with other stimulants. 2. It relieves pain more speedily and effectually than any other known medicine taken into the stomach. If possessed of no other property than this, it would be entitled to high consideration. Not to mention cancer, and other incurable affections, in which the alleviation afforded by opium is of incalculable value, we have numerous instances of painful diseases which are not only temporarily relieved, but entirely cured by the remedy; and there is scarcely a complaint in the catalogue of human ailments, in the treatment of which it is not occasionally demanded for the relief of suffering, which, if allowed to continue, might aggravate the disorder, and protract if not prevent a cure. 3. Another very important indication, which, beyond any other narcotic, it is capable of fulfilling, is the production of sleep. For this purpose it is given in a great variety of diseases; whenever, in fact, morbid vigilance exists, not dependent on acute inflammation of the brain. Among the complaints in which it proves most serviceable in this way is delirium tremens, or the mania of drunkards. Opium produces sleep in two ways; first, by its direct operation on the brain, secondly, by allaying that morbid nervous irritation upon which wakefulness often depends. In the latter case it may frequently be advantageously combined with camphor, or Hoffmann's anodyne. 4. Opium is powerfully antispasmodic. No medicine is so efficient in relaxing spasm, and in controlling those irregular muscular movements which

depend on unhealthy nervous action. Hence its great importance as a remedy in tetanus; colic; spasm of the stomach attending gout, dyspepsia, and cholera; spasm of the ureters in nephritis, and of the biliary ducts during the passage of calculi; and in various convulsive affections. 5. Probably dependent upon a similar influence over the nervous system, is the property which it possesses of allaying general and local irritations, whether exhibited in the nerves or blood-vessels, provided the action do not amount to positive inflammation; and even in this case it is often prescribed with advantage. Hence its use in composing restlessness, quieting cough, and relieving nausea, tenesmus, and strangury. 6. In suppressing morbid discharges, it answers another indication which fits it for the treatment of a long list of diseases. This effect it is, perhaps, enabled to produce by diminishing the nervous energy upon which secretion and muscular motion depend. Upon this principle it is useful in diarrhœa, when the complaint consists merely in increased secretion into the bowels, without high action or organic derangement; in consumption, chronic catarrh, humoral asthma, and other cases of morbidly increased expectoration; in diabetes; and in certain forms of hemorrhage, particularly that from the uterus, in combination with other remedies. 7. It remains to mention one other indication; that, namely, of producing perspiration, in fulfilling which, opium, conjoined with small doses of emetic medicines, is pre-eminent. No diaphoretic is so powerful or so extensively used as a combination of opium and ipecacuanha. We shall speak more fully of this application of the remedy under the head of *Pulvis Ipecacuanhæ Compositus*. It is here sufficient to say, that its beneficial effects are especially experienced in rheumatism, the bowel affections, and certain pectoral diseases.*

From this great diversity of properties, and the frequent occurrence of those morbid conditions in which opium affords relief, it is often prescribed in the same disease to meet several indications. Thus, in idiopathic fevers, we frequently meet with morbid vigilance and great nervous irritation, combined with a low condition of the system. In typhous pneumonia, there is the same depression of the vital powers, combined often with severe neuralgic pains, and much nervous irritation. In diarrhœa, besides the indications presented by the spasmodic pain and increased discharge, there is a strong call for the diaphoretic operation of the opium. It is unnecessary to multiply instances. There is hardly a complaint which does not occasionally present a complication of symptoms demanding the use of this remedy.

But a medicine possessed of such extensive powers may do much injury, if improperly directed; and conditions of the system frequently occur, in which,

* The extraordinary diversity of powers possessed by opium is certainly ascribable in part to the large number of its alkaloids, all of which produce some effect on the system, and between some of which there is a striking difference in effect. Our knowledge, however, of the precise mode of operation of these alkaloids, with the exception of two or three of them, was until recently very deficient, and is still far from satisfactory. M. Claude Bernard has, within a few years, by numerous experiments on the inferior animals, dispelled this ignorance in some degree; but his results must be received with much hesitation, as regards the physiological action on man; and should not be relied on by the practitioner until confirmed by the observation of the physiological experimentalist, and the practical therapeutist. This has been done to a considerable extent in relation to morphia, codeia, narcotina, and very recently to narceia. But in relation to the latter three of these, much remains to be done; and as to the other alkaloids, almost all. The following are the conclusions of M. Bernard, in relation to the six opium alkaloids examined by him. There are three principal properties in these alkaloids: 1. the soporific action; 2. the excitant or convulsive action; and 3. the poisonous action. The six alkaloids may be thus arranged in relation to these actions. In reference to the soporific power, narceia stands first, next morphia, and last codeia. The three others are destitute of the soporific property. In reference to the convulsive power, all have more or less of it; the order in which they stand in this respect being; 1. thebaina; 2. papaverina; 3. narcotina; 4. codeia; 5. morphia; 6. narceia. In the poisonous relation, we have 1. thebaina; 2. codeia; 3. papaverina; 4. narceia; 5. morphia; and 6. narcotina. (*Arch. Gén.*, 6e sér., iv. 462.) For further particulars the reader is referred to the journal just mentioned, and to the author's work on Therapeutics and Pharmacology (3d ed., i. 766).—*Note to the thirteenth edition.*

though some one of the symptoms calls for its use, others, on the contrary, are incompatible with it. Thus, opium is contraindicated by a high state of inflammatory excitement, which should be reduced before we can with propriety venture upon its employment; and, when there is doubt as to the sufficiency of the reduction, the opium should be given in combination with tartarized antimony or ipecacuanha, which modify its stimulant operation, and give it a more decided tendency to the skin. It is also contraindicated by inflammation of the brain, or strong determination of blood to the head, by deficient secretion from inflamed mucous membranes, as in the early stages of bronchitis, and generally by constipation. When, however, the constipation depends upon intestinal spasm, as in colic, it is sometimes relieved by the antispasmodic action of the opium; and the binding effects of the medicine may be counteracted by laxatives.

Opium may be administered in substance or tincture. In the former state it is given in the shape of pill, which, as a general rule, should be formed out of powdered opium, as it is thus more readily dissolved in the liquors of the stomach, and therefore operates more speedily and effectually than when made, as it sometimes is, immediately from the plastic mass. There is no medicine of which the dose is more variable, according to the habits of the patient, the nature of the complaint, or the purpose to be effected. While in catarrh and diarrhœa we often prescribe not more than one-fourth or one-third of a grain, in tetanus it has been administered, without abating the violence of the symptoms, in the enormous quantity of two drachms in twenty-four hours; and in a case of cancer of the uterus, under the care of the late Drs. Monges and La Roche, of this city, the quantity is stated to have been gradually increased till the amount taken during one day, either in the shape of tincture or in substance, was equivalent to more than three ounces. The medium dose, in ordinary cases of disease, to produce the anodyne and soporific effects of the medicine, is one grain.

Experience has shown that the action of opium is sometimes favourably modified by employing those constituents only which are soluble in water. Hence the watery extract is sometimes advantageously substituted for the drug itself, and an infusion for the tincture.* (See *Extractum Opii.*)

Opium may often be administered with great advantage by the rectum. In this way it operates most advantageously in obstinate vomiting, painful nephritic and uterine affections, strangury from blisters, and dysenteric tenesmus. It may be employed as a suppository, or in the form of enema made with laudanum and a small quantity of viscid liquid, as flaxseed tea, mucilage of gum arabic, or starch prepared with hot water. The quantity, as a general rule, may be three times that administered by the mouth; but the relative susceptibility of the stomach and rectum in different persons is not always the same; and the effects produced by the narcotic, given by injection, are sometimes much greater than was anticipated. The practitioner, moreover, should take into consideration the previous habits of the patient. In an individual long accustomed to take opium internally, and whose stomach will receive large doses with impunity, it is possible that the rectum may not have lost, in a proportionate degree, its absorbing power or susceptibility; and that serious consequences might result by adhering, in such a case, to the general rule as to the relative quantity to be given in the way of enema or suppository.

In some one of its liquid preparations, opium is often used locally as an addition to collyria in ophthalmia, to injections in gonorrhœa, and to lotions

* A good extemporaneous infusion of opium cannot well be prepared. Hence, to obtain the effects of this preparation, it is best to dissolve the extract in water. Mr. Eugene Dupuy, of New York, first prepares an infusion, and then adds alcohol enough to preserve it; so that the preparation may be kept ready made by the apothecary, to be used as a substitute for laudanum. He takes ten drachms of opium, reduces it to a thin pulp with water, allows the mixture to stand 48 hours, then percolates with water so as to obtain twelve fluidounces of infusion, to which four fluidounces of alcohol of 95 per cent. are added. The preparation is intended to be of about the same strength as laudanum. Consequently the dose should be from twelve to fifteen minims, or about as many drops. (*Am. Journ. of Pharm.*, xxiii. 211.)

and cataplasms in various complaints of the skin, and external pains, as those of gout and rheumatism. It is also employed in substance, in the form of a plaster or cataplasm made from the powder. But its external use requires some caution, especially when the skin is deprived of the cuticle. Death is said to have resulted from a cataplasm, containing a large quantity of laudanum, applied to the epigastrium. (*Ann. de Thérap.*, 1843, p. 5.)

When opium has been taken in an overdose, the only effectual mode of relief is immediately to evacuate the stomach, either by the stomach-pump, or, when this is not attainable, by the more active emetics, such as tartarized antimony, sulphate of zinc, or sulphate of coppe , conjoined with ipecacuanha. Emetics are preferable to the stomach-pump, when opium has been swallowed in substance; as the capacity of the tube is insufficient to permit the passage of the masses in which the poison is sometimes taken. The operation of the emetic should be promoted by a very free use of warm drinks, by irritating the fauces with a feather, by keeping the patient in motion, and, if the insusceptibility to the action of the remedy is very great, by dashing cold water upon the head and shoulders, thus counteracting, for a moment, the narcotic influence of the opium upon the brain, and enabling this organ to receive and transmit the necessary impressions. Advantage will sometimes accrue from a moderate loss of blood, which tends to diminish the cerebral congestion, and thus not only awaken susceptibility to the impression of the emetic, but obviate also the danger of hemorrhagic effusion; but the bleeding should not be carried far, in consequence of danger from the subsequent debility. For the same purpose of favouring the emetic action, it has been recommended to pass a current of electricity through the brain.* After the evacuation of the poison, the chief indication is to obviate the debility which generally supervenes, and which, when the quantity of the narcotic has been large, or it has remained long in the stomach, is sometimes alarming and even fatal. For this purpose the carbonate of ammonia, or the aromatic spirit of ammonia, with wine-whey, may be employed internally, and sinapisms and stimulant frictions applied to the surface. The practitioner should not despair, even if called at the last moment. The stomach tube may be applied at any period; and it is possible that, even without evacuation of the stomach, a little aid may enable the system to resist the prostrating influence of the poison, if not taken in an overwhelming dose. The electro-magnetic battery was employed with great advantage in a case of prostration of this kind by Dr. Page, of Valparaiso; and the practice has been imitated in Europe and this country. Strong coffee, under these circumstances, has been found useful, and is obviously suggested in all cases by its powerful influence in producing wakefulness. Caffein has been employed as a substitute for coffee; but, as this principle is not the only active one in coffee, it should not be relied on until further tested by experience. Should other measures fail, resort may be had to artificial respiration, by which the functions of the lungs and heart may be sustained till the brain has struggled through its conflict with the narcotic, and is enabled to resume its healthful action. Brodie has demonstrated that death from many of the narcotics results from a suspension of the cerebral influence necessary to sustain the respiratory function, and that the heart ceases to act in consequence of the cessation of respiration. If this can be restored artificially before the contractions of the heart have entirely ceased, the circula-

* From numerous observations recently recorded, there can be no doubt that a certain antagonism exists between opium on the one hand and belladonna and stramonium on the other, so that these poisons are to a certain extent reciprocally antidotal. For what is known on this subject, the reader is referred to a very interesting article by Dr. Wm. F. Norris, in the *American Journal of Medical Sciences* (Oct. 1862, p. 395). In numerous instances, the administration of belladonna freely, in cases of opium poisoning, so far from adding to the narcotic effect, appears to have superseded the influence of the opium by substituting its own; while the opium in the system has rendered innoxious, quantities of belladonna which might otherwise have produced poisonous effects. Nevertheless, our experience on the subject is not yet sufficient to justify us in abandoning the old treatment of evacuating the stomach, and afterwards supporting the system, which has proved efficacious in so many instances. (*Note to the twelfth edition.*)

tion may continue, and life be supported for a time without aid from the brain, which now receives a supply of arterial blood, and is thus better enabled to rise above the repressing action of the opium. As this narcotic does not produce structural derangement, but operates chiefly on the nervous power, a favourable result is more likely to be experienced than in poisoning from some other articles of the same class. Several cases are on record, in which patients, apparently in the very last stage, were saved by a resort to artificial respiration.

OS. *U. S.*

Bone.

OS USTUM. *Br.*

Bone Ash.

The residue of Bones, which have been burned to a white ash in contact with air. *Br.*

Os, *Fr.;* Knochen, *Germ.;* Ossa, *Ital.;* Huesos, *Span.*

Bones are employed in several pharmaceutical processes, and those derived from domestic quadrupeds, especially the ox, are the kind intended.

Properties, &c. Bones are solid, white, and of a lamellated texture, and constitute the skeleton of the superior orders of animals, of which they are the hardest and densest parts. They consist of a cellular gelatinous tissue, the cavities of which are filled with certain earthy salts. When subjected to destructive distillation, in *close* vessels, they are decomposed without alteration of shape, lose about three-sevenths of their weight, become brittle, and are converted into a black substance, containing the earthy salts of the bone, and constituting the species of animal charcoal called *bone-black.* (See *Carbo Animalis.*) The portions which distil over consist of the usual ammoniacal products derived from animal matter. (See *Ammoniæ Murias.*) Before the distillation is performed, the bones are boiled with water, to separate the fat, which amounts to 5 or 6 per cent.; but gelatin is at the same time extracted, with the effect of rendering the bones less fitted to furnish a good bone-black. In view of this fact, M. Deiss, of Paris, has proposed to extract the fat by bisulphide of carbon, which gives a product of 10 or 12 per cent., without injuring the bones for subsequent conversion into bone-black. (*Am. Journ. of Pharm.,* July, 1856, p. 356.) When calcined in *open* vessels, bones lose more of their weight in consequence of the combustion of the animal matter, and are converted into a white friable substance, consisting of the incombustible part, and commonly called *bone-earth,* or *bone-ash;* and a similar residue is obtained by calcining horn. (See *Cornu Ustum.*) Treated with boiling water, a small portion of the gelatinous matter is dissolved; but, when acted on by water in a *Papin's digester,* the whole of it is taken up, and the earthy salts, deprived of their cement, crumble into powder, and become diffused through the solution. When subjected to dilute muriatic acid, the earthy salts are dissolved, and the bone softens without losing its shape, and becomes semitransparent and flexible. The portion remaining unattacked by the acid is the gelatinous tissue, which may be converted into gelatin by long boiling This is nutritious, and has been prepared so as to form a wholesome aliment by M. d'Arcet. His process for obtaining it consists in digesting bones in weak muriatic acid for seven or eight days, occasionally renewing the acid, plunging them

for a few moments in boiling water, and then subjecting them to a strong current of cold water. The pure animal matter, thus procured, is made into cakes, called *portable soup* (*tablettes de bouillon*), by dissolving it in water, concentrating the solution until it gelatinizes, and drying the jelly obtained.

Composition. The bones of different animals, and of the same animal at different ages, vary somewhat in composition. Dry ox-bones, according to Berzelius, consist of bone-gelatin (cartilage of bone) 33·3, bone-phosphate of lime with a little fluoride of calcium 57·35, carbonate of lime 3·85, phosphate of magnesia 2·05, soda with a very little chloride of sodium 3·45 = 100. Human bones differ somewhat in the proportions of their constituents, and in containing traces of iron and manganese. According to Dr. W. Heintz, however, bones exhausted by water, so as to remove the colouring matter of blood, contain not a trace of iron. Marchand found 1 per cent. of fluoride of calcium in human bone. *Bone-phosphate of lime* consists, according to Mitscherlich, of one eq. of acid and three of lime. This analysis makes it the tribasic subphosphate, and the same composition has been assigned to it by Dr. Heintz.

Uses. Bones are applied to numerous uses. Burnt to whiteness, they furnish bone-phosphate of lime, from which phosphorus and all its compounds are either directly or indirectly obtained. (See *Phosphorus.*) Subjected to destructive distillation in close vessels, they yield *impure carbonate of ammonia* and empyreumatic oil, and a carbonaceous residue, called *bone-black.* Calcined, pulverized, and washed, they form the material of which *cupels* are made. As bone-dust, they form an excellent manure. Deprived of their earthy salts by weak acids, they furnish a nutritious article of diet. By proper treatment with water they yield several varieties of gelatin, not only the coarser sorts, called size and glue, but also the finer kinds, which are employed, under the name of isinglass, in making animal jellies, and for the clarifying of wines. (See *Ichthyocolla* and *Cornu.*) The hoof bones of the ox, when boiled with water, furnish a peculiar oil, called neats-foot oil. (See *Oleum Bubulum.*)

OVUM. *U. S.*

Egg.

The egg of Phasianus Gallus. *U. S.*

Off. Syn. OVI VITELLUS. *Yolk of Egg.* The yolk of the egg of Gallus Banckiva, *var.* Domesticus. *Br.*

Œuf, *Fr.;* Ei, *Germ.;* Ovo, *Ital.;* Huevo, *Span.*

The common dunghill fowl is supposed to have come originally from India, where it is found in a wild state. It is now almost everywhere domesticated.

The egg, which is the only officinal product, consists of 1. an exterior covering called the shell; 2. a white, semi-opaque membrane, lining the internal surface of the shell; 3. the white; and 4. the yelk.

1. The shell—*testa ovi* or *putamen ovi*—consists, according to Vauquelin, chiefly of carbonate of lime, with animal matter, and a minute proportion of phosphate of lime, carbonate of magnesia, oxide of iron, and sulphur. When exposed to a high degree of heat in the open air, the carbonic acid is driven off, the animal matter consumed, and the lime is left nearly pure.

2. The membrane lining the shell appears to be of an albuminous nature.

3. The white—*albumen ovi*—is a glairy viscid liquid, contained in very delicate membranes, without odour or taste, readily soluble in water, coagulable by the stronger acids, by alcohol, and by a heat of 160° F. Exposed in thin layers to a current of air, it becomes solid, retaining its transparency and solubility in water. By coagulation it is rendered sapid, white, opaque, and insoluble. At a temperature of 212°, one part of it renders one thousand parts of water in which it has been dissolved opaque. It contains, according to Dr. Bostock, in 100 parts, 85 of water, 12 of pure albumen, 2·7 of mucus or uncoagulable matter,

and 0·3 of saline substances, including soda with traces of sulphur. The white of egg is precipitated by chloride of tin, chloride of gold, subacetate of lead, sulphate of copper, corrosive sublimate, and tannin. When kept in the fluid state it soon putrefies; but, if carefully dried without coagulation, it may be long preserved unaltered, and may be applied in solution to the same purposes as in its original condition.

4. The yelk—*vitellus ovi*—is inodorous, of a bland oily taste, and forms an opaque emulsion when agitated with water. By heat it is coagulated into a granular solid, which yields a fixed oil by expression. M. Gobley found 100 parts of it to contain 51·486 of water, 15·760 of an albuminoid principle denominated *vitellin*, 21·304 of margarin and olein, 0·438 of cholesterin, 7·226 of oleic and margaric acids, 1·200 of phosphoglyceric acid, 0·034 of muriate of ammonia, 0·277 of chlorides of sodium and potassium and sulphate of potassa, 1·022 of phosphates of lime and magnesia, 0·400 of animal extract (*extraite de viande*), and 0·553 of colouring matter, traces of iron, traces of lactic acid, &c. (*Journ. de Pharm.*, 3e sér., xii. 12.) Chevreul states that there are two colouring principles, one reddish containing iron, the other yellow, and similar to the colouring matter of bile. The former is more difficultly soluble in ether than the latter. (*Neues Repertor.*, 1867, xvi. 697.) According to MM. Valenciennes and Frémy, there are both albumen and vitellin in the yelk, the former being dissolved by cold water, the latter precipitated. They consider vitellin as closely analogous to fibrin, from which, however, it differs in not decomposing the peroxide of hydrogen. (*Chem. Gaz.*, Nov. 1, 1855, p. 410.) It is said that the yelk may be kept for a considerable time, without observable change, by adding to it 5 per cent. of sulphate of soda, in powder or concentrated solution.

To preserve eggs in their entire state, M. Bournouf recommends the following method, which he has found to answer well; affirming that he has eaten eggs which had been kept for two years; and he even thinks that the vitality of the germ may be preserved, in the same manner, for a considerable time. The plan consists simply in covering over each egg completely, by the end of the finger, with an ointment consisting of one part of beeswax dissolved in two parts of heated olive oil. The oil is absorbed by the shell, and each of its pores becomes filled with the wax, so as entirely to exclude the air. (*Am. Journ. of Pharm.*, Jan. 1866, p. 88.) Another method has been discovered by Mr. Charles Lamont, and patented, which consists in beating the eggs emptied into a long covered trough, by means of a revolving shaft furnished with a series of metallic disks, and then drying the mass by a current of heated air, and scraping off the concreted egg in thin scales or granules. It is said that the egg retains its flavour and fitness for cooking unimpaired. (*Chem. News*, Dec. 27, 1867, p. 323.)

Medical Properties and Uses. Eggs are applied to various purposes in medicine and pharmacy. The shells, powdered and levigated, may be used beneficially as an antacid in diarrhœa. In common with oyster-shells, they possess the advantage of uniting intimately animal matter with carbonate of lime, the particles of which are thus more thoroughly isolated, and prove more acceptable to the stomach than chalk, in the finest state of division to which the latter can be brought by mechanical means. The dose and mode of preparation are the same as those of oyster-shell. (See *Testa.*)

The *white* of the egg is used chiefly for the clarification of liquids, which it effects by involving, during its coagulation, the undissolved particles, and rising with them to the surface, or subsiding. It is highly recommended as an antidote for corrosive sublimate and sulphate of copper, with which it forms insoluble and comparatively inert compounds. It is sometimes also used for the suspension of insoluble substances in water, but is inferior for this purpose to the yelk, and even to mucilage of gum arabic. Agitated briskly with a lump of alum it coagulates, at the same time dissolving a portion of the alum, and thus forming an astringent poultice, which may be advantageously applied between folds of gauze over the eye, in some states of ophthalmia.

The *yelk* in its raw state is thought to be laxative, and is a popular remedy

in jaundice. If beneficial in this complaint, it is probably in consequence of affording a mild nutritious diet, acceptable to the stomach and easily digested. In dyspepsia it is, from this cause, highly useful. The late Dr. Jos. Parrish, of Philadelphia, found great advantage in that complaint from the habitual use of the yelk of egg, beat up with water and a little ginger. In pharmacy, the yelk is highly useful as an intermedium between water and insoluble substances, such as the balsams, turpentine, oils, &c. It is a mistake to employ the white, instead of the yelk of eggs, in preparing emulsions.

PANAX. *U. S. Secondary.*

Ginseng.

The root of Panax quinquefolium. *U. S.*

Ginseng, *Fr.*, *Germ.*, *Span.*; Ginsen, *Ital.*

Panax. *Sex. Syst.* Pentandria Digynia. (Polygamia Dicœcia, *Linn.*) — *Nat. Ord.* Araliaceæ.

Gen. Ch. Flowers polygamous. *Umbel* simple. *Calyx* five-toothed. *Corolla* of five petals. *Berry* inferior, subcordate, two, sometimes three-seeded. *Calyx* in the male flower entire. *Nuttall.*

Panax quinquefolium. Willd. *Sp. Plant.* iv. 1124; Woodv. *Med. Bot.* p. 149, t. 58; Bigelow, *Am. Med. Bot.* ii 82. The ginseng has a perennial root, which sends up annually a smooth round stem, about a foot high, and divided at the summit into three leafstalks, each of which supports a compound leaf, consisting of five, or more rarely of three or seven petiolate, oblong-obovate, acuminate, serrate leaflets. The flowers are small, greenish, and disposed in a simple umbel, supported by a peduncle, which rises from the top of the stem in the centre of the petioles. The fruit is a kidney-shaped, scarlet berry, crowned with the styles and calyx, with two and sometimes three seeds.

The plant is indigenous, growing in the hilly regions of the Northern, Middle, and Western States, and preferring the shelter of thick, shady woods. The root is the part employed. This is collected in considerable quantities in Ohio and Western Virginia, and brought to Philadelphia and other cities on the seaboard for the purpose of exportation to China, where it is highly valued. Great quantities have recently been collected in Minnesota west of the Mississippi. Some suppose the ginseng plant of Chinese Tartary to be the same as ours; others believe it to be the *Panax Schinseng* of Nees Von Esenbeck; while by others, again, though acknowledged to be a Panax it is thought to be a different species from either of those mentioned. While supplied with this drug exclusively from their own country, which furnished the root only in small quantities, the Chinese entertained the most extravagant notions of its virtues, considering it as a remedy for all diseases, and as possessing almost miraculous powers in preserving health, invigorating the system, and prolonging life. It is said to have been worth its weight in gold at Pekin; and the first shipments from North America to Canton yielded enormous profits. The subsequent abundance of supply has much diminished its value; but it is still in great repute.

The root is fleshy, somewhat spindle-shaped, from one to three inches long, about as thick as the little finger, and terminated by several slender fibres. Frequently there are two portions, sometimes three or more, connected at their upper extremity, and bearing a supposed, though very remote resemblance to the human figure, from which circumstance it is said that the Chinese name *ginseng* originated. When dried, the root is yellowish-white and wrinkled externally, and within consists usually of a hard central portion, surrounded by a soft whitish bark. It has a feeble odour, and a sweet, slightly aromatic taste, somewhat analogous to that of liquorice root. It has not been accurately analyzed, but is said to be rich in gum and starch, and contains albumen. Mr. S. S. Garrigues, of Philadelphia, obtained from it a peculiar substance, which he proposes to call *panaquilon*. To prepare it he heats a cold infusion so as to sepa-

rate the albumen, filters, concentrates to a syrupy consistence, precipitates by a concentrated solution of sulphate of soda, washes the precipitate thoroughly with the saline solution, and then treats it with alcohol, which dissolves the principle in question, and yields it on evaporation. To purify it, he dissolves it in water, treats the solution with animal charcoal, again evaporates, and dissolves the residue in absolute alcohol, which is finally distilled off. Panaquilon is an amorphous yellow powder, soluble in water and alcohol, but not in ether, of a sweet bitterish taste, and has the characteristic property, that, when treated with strong acids, it is converted into a white substance, insoluble in water, with the escape of carbonic acid and water. Mr. Garrigues proposes for this white substance the name of *panacon*. (*Am. Journ. of Pharm.*, xxvi. 511.) The root is sometimes submitted, before being dried, to a process of clarification, which renders it translucent and horny, and enhances its value as an article of export. The extraordinary medical virtues formerly ascribed to ginseng had no other existence than in the imaginations of the Chinese. It is little more than a demulcent, and in this country is not employed as a medicine. Some persons, however, are in the habit of chewing it, having acquired a relish for its taste; and it is chiefly to supply the wants of these that it is kept in the shops. W.

PAPAVER. *U. S.*

Poppy. Poppy Capsules.

The ripe capsules of Papaver somniferum. *U. S.*

Off. Syn. PAPAVERIS CAPSULÆ. *Poppy Capsules.* The nearly ripe capsules of the white poppy, Papaver somniferum, cultivated in Britain. *Br.*

Capsules des pavots, *Fr.;* Kapseln des weissen Mohns, *Germ.;* Capidel papavero, *Ital.;* Cabezas de amapola, *Span.*

Papaver somniferum. See OPIUM.

In England the poppy is cultivated chiefly for its capsules, which are gathered as they ripen, and taken to market enclosed in bags. The Br. Pharmacopœia directs them to be collected before they are quite ripe, as they then contain more of the active milky juice; but, cut at this period, they are apt to lose their juice through the wounded surface, unless carefully kept inverted upon their crown while drying; and, even when thus treated, they are, according to the observations of Buchner, less active than the capsules collected after perfect maturity, while they contain more of useless saccharine and mucilaginous matter. (*Buchner's Repert.*, 3 R., viii. 289 and 326.) M. Meurein states, as the result of his experiments, that the richest are those collected just before the maturity of the seeds, when the capsules have passed from their glaucous-green to a yellowish-green colour. (*Journ. de Pharm.*, 3e ser., xxiii. 341.) They are occasionally imported; but as no effect is produced by them which cannot be as well obtained from opium, or some one of its preparations, they are little employed.

Dried *poppy capsules* vary in size from the dimensions of a small egg to those of the fist. They differ also in shape according to the variety of the poppy from which they are procured. On the continent two sub-varieties of the white poppy are recognised, the *long*, and the *round* or *depressed*. Of these, according to Aubergier, the long are richest in morphia, and his conclusions are confirmed by Meurein, who also found the largest capsules most efficient. Those commonly kept in our shops are spheroidal, flattened below, and surmounted by a crown-like expansion—the persistent stigma—which is marked by numerous diverging rays that rise somewhat above its upper surface, and appear to be prolongations of partial septa, or partitions, proceeding along the interior circumference of the capsule from the top to the bottom. In the recent state, the seeds, which are very numerous, adhere to these septa; but in the dried capsule they are loose in its cavity. The capsules of the black poppy are smaller and more globular than those of the white, and contain dark instead of light-coloured seeds. There appears to be no essential difference in their properties. Both kinds, when fresh, are glaucous, but when dried, as found in the shops, are of a dirty-white or

purplish-brown colour, of a consistence somewhat like that of paper, inodorous, and with little taste, unless long chewed, when they are decidedly bitter. They contain principles similar to those of opium, which they yield to water by decoction, and have been employed in France for obtaining morphia.

Medical Properties and Uses. Dried poppy-heads, though analogous to opium in medical properties, are exceedingly feeble. They are nevertheless asserted, in the form of decoction, to have proved fatal in a child. The case, reported by Dr. F. L. Winckler, was that of a babe, in the stomach of which he found a little morphia, but no meconic acid. (*Neues Repertor.*, 1867, xvi. 38.) They are sometimes employed in decoction, as an external emollient and anodyne application; and, in emulsion, syrup, or extract, are often used internally, in Europe, to calm irritation, promote rest, and produce generally the narcotic effects of opium.

PAREIRA. *U. S.*

Pareira Brava.

The root of Cissampelos Pareira. *U. S.*

Off. Syn. PAREIRÆ RADIX. *Pareira Root.* The dried root of Cissampelos Pareira. *Br.*

CISSAMPELOS. *Sex. Syst.* Dicœcia Monadelphia. — *Nat. Ord.* Menispermaceæ.

Gen. Ch. MALE. *Calyx* four-leaved. *Corolla* none. *Nectary* rotate. *Stamens* four, with connate filaments. FEMALE. *Calyx* one-leafed, ligulate roundish. *Corolla* none. *Styles* three. *Berry* one-seeded.

Cissampelos Pareira. Willd. *Sp. Plant.* iv. 861; Woodv. *Med. Bot*, 3d ed., p. 167, t. 65. This is a climbing plant, with numerous slender, shrubby stems, and roundish, entire leaves, indented at the top, covered with soft hair upon their under surface, and supported upon downy footstalks, inserted into the back of the leaf. The flowers are very small, and disposed in racemes, of which those in the female plant are longer than the leaves. The plant is a native of the West Indies and South America, and is supposed to be the source of the root brought from Brazil, under the name of *pareira brava*. According to Auguste St. Hilaire, however, true pareira is obtained from another species of the same genus, growing in Brazil, and denominated *C. glaberrima;* while by Aublet it is referred to a species of *Abuta*, of the same natural family.*

The root comes in pieces from the thickness of the finger to that of the arm, from a few inches to two or more feet in length, cylindrical, sometimes contorted or forked, and covered with a thin, firmly adhering, grayish-brown bark. The outer surface is marked with longitudinal and annular wrinkles, and sometimes, in the larger pieces, with knotty excrescences. The interior is ligneous, yellowish, very porous, marked by irregular concentric circles, inodorous, and of a sweetish, nauseous, bitter taste. The root imparts its virtues readily to water. M. Feneulle found in it a soft resin, a yellow bitter principle, a brown substance, an azotized substance, fecula, acidulous malate of lime, nitrate of potassa, and various other salts. He considers the yellow bitter substance as the active principle. It is soluble in water and alcohol, and precipitated from its solution by tincture of galls. Wiggers announced, in 1838, the existence in pareira brava of an organic alkali, for which he proposed the name of *cissampelina*. He procured it by boiling the root with water acidulated with sulphuric acid, precipitating by carbonate of potassa, dissolving the precipitate again in water acidulated with sulphuric acid, treating the solution with animal charcoal, precipitating anew with carbonate of potassa, drying and pulverizing the precipitate, treating

* *Pareira Bark.* Though the root is the officinal part, the bark is probably possessed of similar virtues. A specimen which we had the opportunity of seeing at the International Exhibition at London in 1862, was in flat pieces, from two to four inches broad, about a line thick, extremely fibrous, so tough that it could be bent without breaking, of a very light dirty-yellowish colour, and covered with a light-coloured epidermis.

it repeatedly with ether, and evaporating the ethereal solution. The alkaloid thus obtained may be rendered entirely pure by dissolving it in dilute acetic acid, precipitating with carbonate of potassa, and washing and drying the precipitate. (*Annal. der Pharm.*, xxvii. 29.) It is probably the chief ingredient of the bitter substance obtained by Feneulle. Peretti of Rome, and Pelletier afterwards, separated from the root an alkaloid, characterized by assuming a beautiful purple colour by contact with strong nitric acid. (*Journ. de Pharm.*, xxvi. 162.) In Christison's Dispensatory it is stated to be uncrystallizable, insoluble in water, soluble in ether, alcohol, and the acids, and of an intensely bitter and sweetish taste.

Medical Properties and Uses. Pareira brava is said to be tonic, aperient, and diuretic. It was introduced into European practice so long ago as 1688, and at one time enjoyed considerable reputation as a lithontriptic. It has been recommended in calculous affections, chronic inflammation and ulceration of the kidneys and bladder, leucorrhœa, dropsy, rheumatism, and jaundice. The purpose for which it is at present chiefly employed is for the relief of chronic diseases of the urinary passages. Sir Benjamin Brodie found it very useful in chronic inflammation of the bladder, in allaying irritability of that organ, and correcting the disposition to profuse mucous secretion; and it has subsequently come into general use in the same affections. Advantage may often be derived from combining it, in this complaint, with one of the narcotics, as opium or hyoscyamus. In Brazil it is used in the cure of the bites of poisonous serpents; a vinous infusion of the root being taken internally, while the bruised leaves of the plant are applied to the wound. The dose of pareira brava in substance is from thirty grains to a drachm. The infusion, however, is more convenient. (See *Infusum Pareiræ.*) A tincture, made by macerating one part of the root in five parts of alcohol, has been given in the dose of a fluidrachm. The aqueous extract may be given in the dose of from ten to thirty grains. A fluid extract has been prepared, of which the dose is from half a fluidrachm to a fluidrachm.*

PEPO. *U. S.*

Pumpkin Seeds.

The seed of Cucurbita Pepo. *U. S.*

This is one of the officinals newly introduced into the U. S. Pharmacopœia. The *Cucurbita Pepo*, or *common pumpkin*, is a plant too well known to need description. The seeds are the part used. These are oval, extended into a blunt point at one end, flattish, but somewhat swollen in the middle, with a distinct groove on both sides near the edge from one end to the other, when of full size about 9 lines long by 5 or 6 in breadth where broadest, of a light brownish-white colour, and a slightly sweetish, somewhat aromatic smell and taste. They consist of a firm brittle coating, and a white oily kernel; and contain a fixed oil, an aromatic principle, chlorophyll, sugar, gum, and an acid, soluble in water and alcohol, for which the name of *citrullic acid* has been proposed. Deprived of their coating, and exhausted by ether, they yield 30 per cent. of fixed oil (*Annuaire de Thérap.*, A. D. 1862, p. 176.)

Medical Properties. The seeds of the pumpkin have, within a few years, obtained in this country considerable reputation in the treatment of *tapeworm.* This employment of them, however, is not new. In the *Dictionary of Materia*

* *Fluid Extract of Pareira.* This is prepared by Prof. Procter in the following manner. Of the root, in moderately fine powder, 16 troyounces are mixed with 4 fluidounces of Diluted Alcohol, then packed in a conical percolator, and covered with a piece of cloth. Diluted alcohol is now added until three pints of tincture have passed, the first twelve fluidounces being set aside. The remainder is evaporated, by means of a water-bath, to 4 fluidounces, which are mixed with the reserved portion; and the mixture, having been occasionally agitated for 24 hours, is filtered; sufficient alcohol being dropped into the filter to make the product measure a pint. A fluidounce of this represents a troyounce of the root. (*Proceedings of the Am. Pharm. Assoc.*, A.D. 1863, p. 231.)

Medica by Mérat and De Lens (ii. 493), it is stated that Dr. Hoarau had reported that, in the Isle of France, the seeds of a small variety of pumpkin were used against the tapeworm, and with never-failing success. In the year 1820, M. Mongeny, a physician of Cuba, published the results of his experience with the flesh of the pumpkin in the same disease. He had discovered the remedy by accident, and found it uniformly successful. He gave to the patient, in the morning, fasting, about three ounces of the fresh pumpkin in the form of a paste, and followed it at the end of an hour by about two ounces of honey, which latter was twice repeated at intervals of an hour. MM. Brunet and Lamothe, of Bordeaux, verified the statements of M. Mongeny, as to the efficacy of the remedy in tænia, employing, however, a paste made from the seeds, in the quantity of about an ounce and a half, with as much sugar. (*Ann. de Thérap.*, 1853, p. 301.)

In the *Boston Med. and Surg. Journ.* (October 8, 1851, *page* 201) is a communication from Mr. Richard Soule, recommending the seeds in very strong terms as a remedy in tænia; and his letter is preceded by some editorial observations, in which reference is made to the previous successful employment of the remedy by Dr. J. S. Jones, of Boston. Since that time various other notices of the efficacy of the seeds have appeared in the journals, and a very striking case was related to ourselves, on the best authority, in which they had proved immediately and completely successful, after the vain employment of all other known remedies, through a course of several years. Mr. Soule gives the preference to the seeds from the West Indies. The dose of the seeds is about two ounces; which are to be taken in the morning, fasting, and followed in an hour or two by a fluidounce of castor oil. The mode of administration is various. Sometimes the seeds, deprived of their outer covering, are beaten into a paste with sugar, and thus taken. In other instances they are formed into an emulsion, by rubbing them up thoroughly with water and a little sugar.* W.

* The following emulsion, combining the virtues of the pumpkin seeds and male fern, has been recommended in tapeworm. Take of *pumpkin seeds* 600 grains, *sugar* 100 grains, ethereal extract of male fern 60 grains, water five fluidounces. Bruise the seeds in a marble mortar with the sugar, add half a fluidounce of water, and, when a homogeneous paste has been obtained, add the extract of fern, and gradually mix in the rest of the water. The emulsion should be taken without straining, early in the morning, in four doses, at intervals of fifteen minutes; the bottle being well shaken each time.

Oil of Pumpkin Seed. At the suggestion of the late Dr. H. S. Patterson, of Philadelphia, the expressed oil of the seeds was used in a case of tapeworm by Mr. John C. Lyons, and with success. After fasting for 24 hours, the patient took, in the morning, f℥ss of the oil, which was followed in two hours by f℥ss more, and in two hours after the second dose by f℥i of castor oil, which brought away the worm. The oil may be obtained also by the agency of a menstruum. It is probable that, obtained by the action of ether, it would be even more effective than the expressed. A portion of it was extracted from the crushed seeds by means of bisulphide of carbon. The product was 33¼ per cent. of a thick red oil, with little smell, but of a somewhat rank taste. Its sp. gr. at 60° F. was 0·928. (G. A. Gross, *Am. Journ. of Pharm.*, July, 1865, p. 253.)—*Notes to the twelfth and thirteenth editions.*

erect, branching stem, about two feet in height. The radical leaves are compound, pinnated in ternaries, with the leaflets smooth, divided into three lobes, and notched at the margin. In the cauline leaves, the segments of the leaflets are linear and entire. The flowers are small, pale-yellow, and disposed in terminal compound umbels, with a one or two-leaved general involucre, and partial ones composed of six or eight leaflets. The petals are five, roundish, and inflexed at their apex. The seeds (half-fruits) are small, ovate, flat on one side, convex on the other, dark-green, and marked with five longitudinal ridges. They have a strong, terebinthinate odour, and a warm aromatic taste.

The plant is a native of Sardinia, and other parts of Southern Europe, and is cultivated everywhere in gardens. All parts of it contain a volatile oil, to which it owes its odour and mainly its taste, as well as its use in seasoning. M. H. Braconnot obtained from the herb a peculiar gelatinous substance, resembling pectic acid in appearance, which he named *apiin*. It differs from pectin in being more soluble in alcohol than cold water, in not being precipitated by alcohol from its watery solution, and in being separated by acids from its alkaline solutions unaltered, whereas pectin is under these circumstances converted into pectic acid. (*Journ. de Pharm.*, 3e sér., xix. 448.) It is procured by boiling the herb in water, straining the liquor, and allowing it to cool. The apiin then forms a gelatinous mass, which requires only to be washed with cold water. (*Philos. Mag.*, xxiv. 155.) Though the root is the part directed by the Pharmacopœia, the fruit is at least equally efficient. Examined by MM. Joret and Homolle, the seeds were found to contain a volatile oil, a crystallizable fatty matter, pectin which they believe to be the apiin of Braconnot, chlorophyll, tannin, a colouring matter, extractive, lignin, various salts, and, in addition to these, a peculiar substance to which they gave the name of *apiol*. This is a yellowish oily liquid, not volatile, heavier than water, of a peculiar and tenacious odour distinct from that of the plant, and an acrid pungent taste. It is inflammable, in soluble in water hot or cold, very soluble in alcohol, and dissolved in all proportions by ether and chloroform. It is analogous to the fixed oils, but is not chemically modified by the alkalies. It contains no nitrogen. To obtain it MM. Joret and Homolle exhausted the seeds with alcohol, treated the tincture with purified animal charcoal, distilled off three-fourths of the alcohol, treated the residue with ether or chloroform, evaporated the solution thus formed, mixed the residuary liquid with an eighth of its weight of litharge, allowed the mixture to rest twenty-four hours, and then filtered through a light layer of charcoal. Apiol is supposed by its discoverers to be the antiperiodic principle of parsley.

The root is spindle-shaped, about as thick as the finger, externally white, and marked with close annular wrinkles, internally fleshy and white, with a yellowish central portion. It has a pleasant smell, and a sweetish, slightly aromatic taste; but loses these properties by long boiling, and by time. It should be employed in the recent state.

Medical Properties and Uses. Parsley *root* is said to be aperient and diuretic, and is occasionally used in nephritic and dropsical affections, in connection with more active medicines. It was highly recommended by Professor Chapman. The usual form of administration is that of strong infusion. A decoction of the leaves, applied warm to the eye by means of a compress, has been employed with benefit by Dr. Neucourt in recent ophthalmia. (*Am. Journ. of Med. Sci.*, July, 1865, p. 257.) The *juice* of the fresh herb has been employed as a substitute for quinia in intermittents; and the *seeds*, as well as their supposed active principle, have been given with great asserted success in the same complaint. According to MM. Joret and Homolle, *apiol* acts on the system very much like quinia, producing, in the dose of about 15 grains, a slight cerebral excitation without unpleasant effects of any kind, and, in double or quadruple the quantity, giving rise to a species of intoxication, with giddiness, morbid sights and sounds, frontal headache, and all the characteristic effects of a large dose of sulphate of quinia. They found it to cure intermittents, in temperate latitudes, in the proportion of 86 per cent. of the cases; and, though

it proved less effectual in tropical regions, they seem to have shown that, in the absence of Peruvian bark or its preparations, it might be usefully resorted to as a substitute.* W.

PHOSPHORUS. *U. S., Br.*

Phosphorus.

Phosphore, *Fr.;* Phosphor, *Germ.;* Fosforo, *Ital., Span.*

This non-metallic element was discovered in 1669 by Brandt, an alchemist of Hamburg, who obtained it from putrid urine by a process which remained a secret until 1737. As thus procured it was exceedingly scarce and costly. In 1769, the Swedish chemist Gahn discovered it in bones, and shortly afterwards published a process by which it might be extracted from them.

Preparation. Powdered calcined bones (bone-phosphate of lime) are digested for twenty-four hours with two-thirds of their weight of sulphuric acid previously diluted with twelve times its weight of water. The sulphuric acid separates the greater part of the lime from the phosphoric acid, and precipitates as sulphate of lime; while a superphosphate of lime remains in solution. The liquid is then strained through a linen cloth to separate the sulphate of lime, and afterwards submitted to evaporation, which causes a fresh precipitation of sulphate, to be separated by a new straining. The strained solution is evaporated to a syrupy consistence, and then thoroughly mixed with half its weight of powdered charcoal, so as to form a mass, which is dried by being heated to dull redness. The mass when cool is quickly transferred to a coated earthenware retort, furnished with an adapter of copper, bent downwards at right angles, so as to enter a bottle with a large neck containing water, which should rise about two lines above the orifice of the adapter. The bottle is closed round the adapter with a cork, which is traversed by a small glass tube, to give exit to the gaseous products. The retort is heated in a furnace, furnished with a dome, in the most gradual manner, so as to occupy about four hours in bringing it to a red heat. Afterwards the heat is pushed vigorously, so long as any phosphorus drops into the water; and this takes place generally for from twenty-four to thirty hours. During this part of the process, the excess of acid in the superphosphate is decomposed; its oxygen combining with the charcoal, and the liberated phosphorus distilling over. The calcined bones of the sheep are preferred; as they contain the largest proportion of phosphate of lime, and are most readily acted on by the acid.

M. Cari-Montrand proposes to obtain phosphorus by passing dry muriatic acid gas over a mixture of equal parts of bone-phosphate of lime and finely powdered charcoal, contained in a porcelain tube, to which a glass tube is attached, dipping under water. Phosphorus and water distil over, carbonic oxide is evolved, and chloride of calcium is left. The following equation explains the reaction: $3CaO,PO_5$ and 5C and 3HCl = P and 3HO and 5CO and 3CaCl.

The following improved process for obtaining phosphorus on a large scale is given by Hugo Fleck, of Germany. Clean, broken bones, deprived of fat, are digested in dilute muriatic acid, which gives rise to the formation of chloride of calcium, and acid phosphate of lime ($CaO,2HO+PO_5$). The bone cartilage, remaining undissolved by the acid, is used for preparing gelatin. The solution is evaporated in pans until its sp. gr. is about 1·4, and then run off to cool, when the acid phosphate crystallizes. This salt, having been separated from the mother-liquor by being pressed between cloths and dried, appears as a white gritty powder with a pearly lustre. The dry salt, warmed, and mixed with a fourth of its weight of charcoal, is distilled from clay cylinders, like gas re-

* Since the announcement of the antiperiodic properties of apiol, it has been found to possess other virtues also. By MM. Joret and Baillot and other practitioners it has been employed, with much success, as an emmenagogue in amenorrhœa and dysmenorrhœa, in the dose of about four grains morning and evening; being taken in the former affection in anticipation of the menstrual period, in the latter during its continuance. It is said also to have proved useful in the night-sweats of phthisis. From its unpleasant taste, it is most conveniently exhibited in capsules of gelatin. (*Journ. de Pharm.*, Juin, 1861, p. 456.)

torts. Every five cylinders open into one receiver, shaped like a muffle, and contained in a channel through which water flows. The residual bone-phosphate of lime, in the cylinders, is incinerated upon iron plates to burn away the charcoal, and is thus saved to prepare fresh acid phosphate. By this process 100 lbs. of fresh bones yield from 6 to 7 lbs. of phosphorus, and from 10 to 20 of gelatin; while the process usually pursued gives only 4 or 5 lbs. of phosphorus. (*Pharm. Journ.*, Sept. 1856, p. 175.)

Properties. Phosphorus is a semitransparent solid, without taste, but possessing an alliaceous smell. When perfectly pure it is colourless; but as usually prepared it is yellowish or reddish-yellow. It is flexible, and when cut exhibits a waxy lustre. It is said by M. Bœttger to be easily pulverizable by agitation with a solution of urea. (*Journ. de Pharm.*, Juin, 1863, p. 488.) It is insoluble in water, but dissolves sparingly in ether, anhydrous alcohol, and the oils, and abundantly in bisulphide of carbon and chloroform. Its sp. gr. is 1·84, and its equivalent number 32 (31·02 Schroetter). Its pulverization may be readily effected by melting it in hot water, and agitating until it is thoroughly cooled; and the powder is obtained finer in saline solutions than in pure water. (Blondlot, *Journ. de Pharm. et de Chim.*, 4e sér., i. 72, A. D. 1865.) It takes fire at 100°, melts at 108°, and boils at 550°, air being excluded. During its combustion it combines with the oxygen of the air, and forms dry phosphoric acid. On account of its great inflammability, it must be kept under water. When exposed to the air it undergoes a slow combustion, emitting white vapours, which are luminous in the dark. It sometimes contains arsenic, and, therefore, when used in forming medicinal preparations, should be tested for that metal. It also occasionally contains antimony and sulphur. The latter impurity renders it brittle.

When phosphorus is kept in ordinary water it becomes covered with a whitish layer, of the nature of which there are different opinions, being considered by some a hydrate of phosphorus, by others as an allotropic condition of that element, and by others again as partially crystallized; but all these opinions have been disproved by M. Ernest Baudrimont, who seems to have demonstrated that *white phosphorus* is entirely identical with that principle in its ordinary state, and results from a kind of erosion of the surface, owing to partial oxidation by the free oxygen held in solution by the water. The change never takes place in water entirely deprived of air; and the water when it has taken place holds phosphorous acid in solution. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 17, A. D. 1866.)

Prof. Schroetter, of Vienna, discovered an allotropic form of phosphorus, which he called *red* or *amorphous phosphorus*. It is formed when ordinary phosphorus is kept long at a temperature between 419° and 482° F., in atmospheres which have no action on it, or in closed glass tubes. Red phosphorus is much more indifferent than the ordinary substance, and is denser, its sp. gr. being 2·11. It is much less easily acted on by the air than ordinary phosphorus, and is insoluble in bisulphide of carbon, alcohol, and ether, in which ordinary phosphorus is soluble. Solidified from the fused state, it is brittle, and breaks with a conchoidal fracture. Its hardness is considerable. Obtained by distillation in a non-acting gas, it is mixed with ordinary phosphorus, from which it may be freed by bisulphide of carbon, which dissolves the ordinary variety, and leaves the allotropic as a deep-red amorphous powder. It may also be purified by shaking it with a solution of chloride of calcium, of a density intermediate between that of red and ordinary phosphorus, and with a little bisulphide of carbon. The red variety will sink to the bottom, and the ordinary float on top of the solution, dissolved in the bisulphide (*E. Nicklès.*) Red phosphorus is not poisonous. This has been proved beyond a doubt by the experiments of MM. Reynal and Lassaigne, and of MM. L. Orfila and Rigaut. It is applicable to the manufacture of lucifer matches, and forms a much safer material than ordinary phosphorus. It does not take fire by friction at common temperatures, and, therefore, may be transported with the greatest safety. It has been said to be unchangeable in the air; but this is not exactly true, as

proved by an observation of Mr. T. B. Groves, who, having set aside some red phosphorus in a bottle that was not air-tight, observed for a year or more no visible change, but found at length that it had become decidedly altered, and ascertained that oxidation had taken place, with the result of forming a large quantity of phosphoric and phosphorous acids, in the proportion of 5 eqs. of the former to 2 of the latter. (*Pharm. J. and Trans.*, June, 1865, p. 621.)

Besides the white and red forms of phosphorus, there is another, called the *black*, first noticed by Thenard, and recently investigated by M. Blondlot, who finds that it is pure phosphorus, and its production owing to some modification in the mode of cooling, when it has been in the liquid state. (*Journ. de Pharm. et de Chim.*, 4e sér., i. 407, A. D. 1865.)

Still another modification of phosphorus has recently been made known by M. Hittorf, who obtained it by heating red phosphorus and lead together in a close vessel. The lead on melting dissolved the phosphorus, and on cooling deposited it in the state of crystals, resembling the crystals of arsenic. In this form, phosphorus is a conductor of electricity; and its sp. gr. at 62° F. is 2·34. M. Hittorf distinguishes it by the name of *metallic phosphorus*, and ranks it in the same category with red phosphorus, the latter differing simply in being amorphous. (*Chem. News*, March 23, 1866, p. 133.) M. Blondlot has succeeded in crystallizing common phosphorus by means of sublimation, operating in an atmosphere of nitrogen. (*Journ. de Pharm. et de Chim.*, 4e sér., iv. 321.)

Phosphorus forms with oxygen hypophosphorous, phosphorous, and phosphoric acids. Of the last-mentioned acid there are three varieties, distinguished by containing, severally, one, two, or three eqs. of water. The only officinal compounds containing phosphorus are glacial and diluted phosphoric acids, phosphate and pyrophosphate of iron, and the phosphates of ammonia, lime, and soda.

Medical Properties. Phosphorus, exhibited in small doses, acts as a powerful general stimulant; in large doses, as a violent irritant poison. There is little if any doubt that, when not oxidized in the stomach, it is absorbed into the system, probably dissolved in oleaginous matter, and operates through the blood. Its action is directed particularly to the kidneys and genital organs, producing diuresis, and excitation of the venereal appetite. From its peculiar physiological action, it is considered applicable to diseases attended with prostration of the vital powers. It has been recommended in impotency, typhoid and typhus fevers, dropsy, phthisis, marasmus, chlorosis, paralysis, locomotor ataxia, amaurosis, mania, facial neuralgia, &c. In certain obstinate cutaneous diseases, particularly eczema and psoriasis, it has been used with advantage. (*Med. Times and Gaz.*, Jan. 1868, p. 619.) Those who work in phosphorus, as the manufacturers of lucifer matches, are liable to necrosis of the jaw-bones, the consequence of periostitis. The affection is probably produced by the inhalation of air contaminated with phosphorus vapour, which has a local action on the teeth, gums, and jaws, and a general deteriorating effect on the blood. Dr. James R. Wood has recorded, in the *N. Y. Journ. of Med.* for May, 1856, an interesting case of a girl of sixteen, in which the entire lower jaw was removed for necrosis caused by phosphorus.

The usual form for exhibiting phosphorus is in oily solution. The *Oleum Phosphoratum* of the Prussian Pharmacopœia is made as follows. Take of phosphorus *twelve grains;* almond oil, recently prepared, *an ounce.* Melt the phosphorus in the oil by the heat of warm water, and agitate until it appears to be dissolved. The ounce of oil takes up about four grains of phosphorus; and the dose of the solution is from five to ten drops, mixed with some mucilaginous liquid. An aromatic flavour may be given by the addition of a few drops of oil of bergamot. In an article in the *Archives Générales* (Mai, 1868, p. 609) it is maintained that the purest almond oil of the shops always contains water and organic matters dissolved or suspended, which react on the phosphorus, and so far modify its condition as to render the dose uncertain. To obviate this inconvenience, it is recommended to heat the oil, in the open air, for half an hour, at a temperature of about 300° F. at first, gradually increased to 350°.

The water and organic impurities are thus driven off; and the oil, having been filtered, and allowed to cool, is introduced into bottles with ground glass stoppers, and kept for use. Dr. R. M. Glover has proposed to give phosphorus, dissolved in chloroform or cod-liver oil. He makes the chloroform solution, which is non-inflammable, by dissolving one part of phosphorus in four of chloroform. Of this solution he gives four or five minims, twice a day, with a drachm of ether, in a wineglassful of port wine, in typhoid fever. The solution in cod-liver oil is effected by adding the phosphorus, in chips, to the oil contained in a bottle, in the proportion of half a grain to the ounce The bottle is then immersed in hot water, and the solution effected by shaking. This mode of giving phosphorus was used by Dr. Glover in strumous cases. (See *Braithwaite's Retrospect*, Am. ed., xxvii. 246.) Phosphorus has been given with success in intermittents, dissolved in oil of turpentine. (*Trans. of the Med. Soc. of Pennsylvania*, iv. 119.) M. Tavignot gives pills made from an oleaginous solution of phosphorus. One and a half grains are dissolved, by means of a water-bath, in two drachms of almond oil; the solution is made into a pill mass by mixing it with two drachms of almond oil soap and a sufficient quantity of an inert powder; and the mass is divided into 100 pills. From two to four of the pills may be taken daily. (*Journ. de Pharm.*, Août, 1863, p. 137.) Dr. Crawcour shakes phosphorus cut fine in a bottle with boiling absolute alcohol until cold. The alcohol dissolves about two grains to the fluidounce, and from 30 to 60 drops of the solution may be given with a wineglassful or two of water. (*Med. Times and Gaz.*, Feb. 1859, p. 222.) Great caution is necessary in the exhibition of phosphorus, and its effects should be closely watched. It ought never to be given in substance.

Phosphuret of zinc has been suggested as a substitute for phosphorus itself, having similar effects on the system, and being much more convenient of administration. It may be prepared by bringing the vapour of phosphorus into contact with zinc heated to ebullition, in a current of dry hydrogen. It is of a gray colour, a crystalline texture, and metallic lustre, unchangeable in the air, and easily affected by acids, which attack it in the stomach, evolving phosphuretted hydrogen, through which it operates. It may be given in pills made with liquorice powder and syrup of gum arabic, in the dose of about one-thirtieth of a grain. (*Journ. de Pharm. et de Chim.*, Mai, 1868, p. 371.)

Toxical Properties and Tests. Phosphorus, taken in a poisonous dose, produces violent inflammation of the stomach and bowels, with intense pain, obstinate vomitings, tremblings, and, finally, convulsions on the approach of death. If swallowed in sticks on a full stomach, the poisonous symptoms are some hours in manifesting themselves. When taken in substance, two or three grains of tartar emetic should be given to dislodge it. If swallowed in the state of solution, copious draughts of cold water, containing magnesia in suspension, should be administered, in order to prevent the combustion of the phosphorus, and to neutralize any acid which may have been formed. A case is related by Dr. Landerer, in which a child who had swallowed nearly a teaspoonful of phosphorus paste,* prepared for killing rats, was saved by the free administration of magnesia, rubbed up with sugared water. Cases of supposed poisoning by phosphorus matches have been recorded. Messrs. Antonielli and Borsarelli have shown, by numerous experiments on animals, that fatty matter increases the poisonous activity of phosphorus, and that the best antidote is calcined magnesia given largely with water. (*Lancet*, Feb. 5, 1859, p. 136.) Duflos has proposed, as an antidote, a mixture of one part of magnesia and eight of chlorine water. From experiments on rabbits, A. Bechert inferred that this mixture would prove useful; but similar experiments, made by Schrader, L. Hofmann, and Schuchardt, were without effect. It is said that the vapour from oil of tur-

* This paste is made as follows. Triturate six parts of phosphorus and one part of sulphur with six parts of water, until they liquefy. Then mix in two parts of flour of mustard, eight parts of sugar, and twelve parts of rye flour, with the aid of ten additional parts of water, and stir the whole so as to form a soft paste, which must be kept in pots closely stopped. (See *Am. Journ. of Pharm.*, Sept. 1855, p. 473.)

pentine acts as an antidote to that of phosphorus, when the two are inhaled together. (*Arch. Gén.*, Juillet, 1868, p. 103.) From experiments on dogs poisoned by phosphorus, MM. L. Orfila and Rigaut have shown that putrefaction is remarkably retarded. In a case of chronic poisoning from the copious inhalation of phosphorus vapour, the principal results were a gradual decay of the sexual function and paralysis, terminating in death at the end of three years. Partial or general paralysis is a not uncommon result. (*Lancet*, July 7, 1866, p. 23.) One of the most remarkable post-mortem appearances in cases of phosphorus poisoning, is fatty degeneration of the liver; and the same pathological condition has been found in the heart. (*Guy's Hosp. Reports*, xiii. 242, A.D. 1868.)

E. Mitscherlich gives the following as a delicate test of phosphorus. The suspected substance is distilled with sulphuric acid and water from a flask, by means of a tube bent twice at right angles, into a vertical cooling tube, passing through the bottom of a wide glass cylinder filled with water, which is constantly kept cold by passing cold water in at the bottom, while the warm water escapes at the top. Under the cooling tube is placed a vessel to receive the distillate. If phosphorus is present, its vapour, mixed with steam, distils over, and gives rise to a distinct luminous appearance, visible in the dark, at the point where it enters the cold part of the cooling tube. The presence of alcohol and ether prevents the occurrence of the luminous appearance until they have distilled over. Oil of turpentine has the same effect permanently, but is not likely to be present in medico-legal cases. (*Am. Journ. of Med. Sci.*, July, 1856, p. 280; from the *Lancet*.) This test acts equally well in the presence of fatty matters, as has been shown by M. Vrij. L. Hofmann gives the following method of detecting phosphorus in the viscera in cases of poisoning. The viscera, mixed with water and a little sulphuric acid, are distilled until two drachms of liquid are obtained; to which a few drops of sulphide of ammonium (hydrosulphate of ammonia) are to be added, and the liquid is to be evaporated to dryness in a porcelain dish. If phosphorus be present, in the minutest quantity, a drop of solution of perchloride of iron will produce a deep violet and brownish, though evanescent colour, through its reaction. (*Chem. News*, Feb. 3, 1865, p. 53.)

The use of phosphorus as a disinfectant has been suggested by its extraordinary power of ozonizing the oxygen of the air, whereby noxious effluvia may be destroyed. A stick of it should be placed in an infected apartment, and so arranged that one half shall be immersed in water, the other half projecting.

PHYSOSTIGMATIS FABA. *Br.*

Calabar Bean.

The seed of Physostigma venenosum (*Balfour*). *Br.*

Physostigma. *Nat. Ord.* Leguminosæ. *Sub. Ord.* Papilionaceæ. *Tribe* Euphasiolæ.

Gen. Ch. Inflorescence axillary; on pendulous multifloral racemes; rachis of each raceme zigzag. *Calyx* campanulate, four-cleft at apex, the upper division notched, its segments ciliated. *Corolla* papilionaceous, curved in a crescentic manner. *Stamens* 10, diadelphous. *Pistil* more than one. *Stigma* blunt, covered by a ventricular hood, extending along the upper part of the convexity of the style. *Legume* dark-brown and straight, elliptico-oblong, with an apicular curved point, and outer and inner integuments easily separable. *Seeds* two or three, separated by a woolly substance. *Balfour.*

Physostigma venenosum. Balfour, *Transactions of the Royal Society of Edinburgh*, xxii. 305; *Ed. Med. Journ.*, July, 1863, p. 34. This is a climbing plant, with a ligneous stem, mounting on trees and shrubs, and frequenting especially the banks of streams, into which it often drops its fruit when ripe; and it is said that the people of Calabar derive their supply principally from the borders of the streams down which the fruits are carried. The root is spreading, with numerous fibrils, often having attached to them small succulent tubers.

The flowers are in axillary, multiflorous, pendulous racemes. The corolla is papilionaceous, of a pale pink colour, with a purplish tinge. The legume when ripe is about seven inches long, and contains two or three seeds. It ripens at all seasons, but is most abundant during the rainy season from June to September. The seeds are the part used. The plant is the only known species.

It has been long known that certain poisonous substances were used as an ordeal, to determine the guilt or innocence of accused individuals, among the Negroes of Western Africa. One of these, called the ordeal bean of Calabar, from the region where it is used, was brought to the notice of the scientific public by Dr. Daniell, in a paper read before the Ethnological Society of Edinburgh in 1846. Considerable attention was attracted to the subject; and specimens of the bean were obtained by Dr. Christison from the Gold Coast. These were planted in the Botanical Garden at Edinburgh, and produced a plant, which proved to be a perennial creeper, belonging to the natural family *Leguminosæ;* but at the date of the publication of the 11th edition of this work, early in 1858, the precise botanical position of the plant had not been determined. In the year 1859, specimens of the plant were sent from Calabar, which came under the observation of Dr. Balfour, of Edinburgh, who was thus enabled to ascertain its botanical character. He communicated the results of his examination to the Royal Society of Edinburgh; and his paper is published, with a particular description of the plant, in its *Transactions* (vol. xxii. p. 305). Having found that the plant belonged to a yet undescribed genus, he established a new one with the title of *Physostigma*, suggested by a peculiar inflation of the stigma; and designated the species as *venenosum*, from the notorious qualities of the fruit. In the *Edinburgh Medical Journal* (July, 1863, p. 36) is an essay by Dr. Thos. R. Fraser, containing a summary of what was known on the subject of the bean up to that date, with a particular description of the bean, and an account of experiments made with it on animals.

Properties. The seed is about the size of a large horse-bean, being somewhat more than an inch in length by three-fourths of an inch in breadth, with a very firm, hard, brittle, shining integument of a brownish-red, pale-chocolate, or ash-gray colour. The shape is irregularly kidney-form, with a longer convex and a shorter concave edge, two flat sides, and a furrow running longitudinally along its convex margin, and ending in an aperture near one of the extremities of the seed. Within the shell is a kernel consisting of two cotyledons, weighing on an average about 46 grains, hard, white, and pulverizable, of a taste like that of the ordinary edible leguminous seeds, without bitterness, acrimony, or aromatic flavour. The bean yields its virtues to alcohol, and imperfectly to water. The shell constitutes, according to Dr. Edwards, 30 per cent., the kernel 70 per cent. of the bean. Jobst and Hesse were thought to have succeeded in isolating the active principle, which they found exclusively in the cotyledons. They obtained it by exhausting an alcoholic extract of the seeds with water, adding magnesia to neutralization, which is indicated by the liquid becoming brown, then concentrating, and treating with ether. The ethereal solution was shaken with a little weak sulphuric acid. The liquid separated into two layers; the upper, ethereal, containing no alkaloid, and the lower, a solution of the sulphate in water. The latter was separated, treated with magnesia, and afterwards with ether, which yielded the alkaloid on evaporation. The substance thus obtained they proposed to name *physostigmin.* It was brown, amorphous, soluble in ammonia, soda, ether, benzole, and alcohol, and less so in cold water Its watery solution had an alkaline reaction, and formed salts with the acids. Iodide of potassium precipitated it of a dark-brown colour. Melted with potassa it yielded alkaline vapours. (*Journ. de Pharm.*, Mars, 1864, p. 277.)

But the physostigmin thus obtained proved to be a complex body, containing the active principle associated with other substances. The pure alkaloid has been subsequently isolated by MM. Amédée Vée and Manuel Leven. They procured it by adding to a carefully prepared extract, made by exhausting the powdered seeds with cold alcohol of 95 per cent. a strong solution of

tartaric acid, diluting the mixture with water, filtering, adding powdered bicarbonate of potassa in excess, again filtering, and shaking with ether, which yields the alkaloid impure on evaporation. To purify it, the residue was deprived of moisture by putting it under a bell-glass over strong sulphuric acid, was then treated with ether, and the ethereal solution allowed to evaporate spontaneously. Repeated solution in ether and crystallization were still necessary to free it from a red colouring matter, which adhered to it very tenaciously. The pure alkaloid is colourless, crystallizable in thin rhomboidal plates, slightly bitter, soluble in ether, alcohol, and chloroform, and but slightly so in water, to which, however, it gives a decided alkaline reaction. It is readily dissolved by the acids, and is precipitated by the substances which generally precipitate the alkaloids. It is fusible, and at a high heat gives out white vapours, and burns without residue. Its salts are generally soluble. Its solution acts quickly on the pupil, and a drop of a solution containing only 1 part in 1000, placed within the eyelids, causes great and lasting contraction. The discoverers of this principle named it eserin (*eserina*); but we prefer the first name of physostigmin (*physostigmia*). Of this alkaloid 1·5 milligrammes (·023 gr.), injected under the skin of a guinea-pig, produced palsy of the hind legs in five minutes, and death in half an hour, with dilatation of the pupil at the time of death. It is said to be capable of destroying life by absorption from the conjunctiva. A peculiarity of the alkaloid is that an aqueous solution of it or one of its salts, exposed to the air in the presence of potassa, soda, or lime, becomes red, owing to the absorption of oxygen. The colouring matter is taken up by chloroform. The colour is not permanent, but gradually changes to yellow, green, or blue. This test will detect less than the 100-thousandth part of the alkaloid. The same property is possessed by the alcoholic extract of the bean.

Effects on the System. The bean is the only part known to possess medicinal properties. The shell is not without influence on the animal system, as shown by experiments upon rabbits made by Dr. Fraser, who found it to purge, increase the flow of urine, and produce temporary paralysis of the extremities, but without loss of consciousness; and, though a quantity of extract equivalent to a drachm of the shell was given, it did not cause death. The kernel, however, is by far the most active part, as a rabbit was killed by five and a half grains of it. The most prominent effects of this part of the bean were obviously on the spinal marrow, and, as believed by Dr. Fraser, of a depressing character. They were paralysis, loss of reflex action, contraction of the pupil, occasionally evacuation of the bowels, with retention of consciousness until all power of expression ceased. Immediately after death the pupils dilated. No changes of structure were discoverable which could explain the phenomena. The brain and spinal marrow were apparently normal, and the heart full of blood. Similar effects were produced by topical application. The function of the part was suspended. The cardiac action and the vermicular movements of the bowels ceased by contact with the poison; and a little of it applied to the eye, produced contraction of the pupil of that eye, but not of both. The general conclusions of Dr. Fraser were, that the kernel has a depressing action on the spinal cord, causing death by paralysis, in some instances of the respiratory muscles, in others of the heart. One of the most interesting results of his experiments appears to be, that the integument of the seed, though possessing in a slight degree the powers of the kernel over the nervous system, differs from it in being actively cathartic.

In reference to the effects of the medicine upon the human system, much yet remains to be learned. It was known that the beans used by the natives as an ordeal, when given in a certain quantity, generally proved fatal, and the individual only escaped when they provoked vomiting, which was rare. A draught containing 19 seeds pounded and infused in water killed a man in an hour. It would be a subject of interesting inquiry, whether the integuments might not, in certain quantities, act energetically as an emetic as well as cathartic; and whether the escape of the accused person, in some instances, might not be owing to the accidental or contrived exhibition of a larger than ordinary proportion

of this part of the seeds. Dr. Christison took about 12 grains of the kernel, which in 15 minutes produced giddiness and a feeling of torpidity, followed by great weakness and faintness, paleness of the surface, extreme weakness and irregularity of the pulse, and indisposition or inability to make voluntary muscular effort. There was no pain or other uneasiness, except the feeling of prostration and some nausea, and the intellect was normal. In two hours after the poison was swallowed, drowsiness occurred, but no stupor. Dr. Fraser experienced from smaller doses effects of a similar character, with temporary dimness of vision. The heart appears to be somewhat variously affected, sometimes acting irregularly or tumultuously, and sometimes less frequently. A peculiar epigastric sensation is generally experienced as the first symptom, about five minutes after the taking of the medicine, gradually increasing, and becoming at length almost painful. This continues at intervals for a considerable time, is after a little while attended with some dyspnœa; and then dizziness and feebleness of the extremities are experienced.

On the whole, it would appear that the calabar bean is a direct sedative to the spinal marrow, thus producing muscular debility or relaxation, and when largely given, causing even palsy; and in poisonous doses acting by paralyzing the heart and respiratory muscles. It produces no loss of consciousness or stupor, and thus differs from the cerebral sedative. Besides its action as a spinal sedative, it is more or less irritant to the alimentary canal, often vomiting or purging, and thereby saving life when taken in poisonous quantities. Seventy cases of children are related, who ate more or less of some beans on their arrival from Africa at the wharves of Liverpool, in all of whom vomiting was brought on either by the poison itself, or by emetics administered, except in a single case; and that case was the only one that proved fatal. The nausea and vomiting came on in about 30 minutes; the nervous symptoms, as trembling, dizziness, and loss of muscular power, in less than an hour. In the fatal case four kernels had been eaten. Ordinarily in cases of death from calabar bean there are no positive post-mortem phenomena; the brain and spinal marrow being free from congestion. The remedies in cases of poisoning are emetics, as sulphate of zinc and ipecacuanha; and stimulants to support the vital actions.

The most interesting effect of the calabar bean, so far as its practical application is concerned, is that of contracting the pupil; an effect resulting either from its internal or local use. It is most conveniently obtained by introducing a drop of watery solution of the alcoholic extract into the eye. Only the eye operated on is in this case affected. It is highly probable that the effect is produced by a debilitating or paralyzing influence on the spinal centres, whereby the action of the expanding fibres is suspended, and the contractile influence from the cerebral centres is left unimpeded. Another effect on the eye, more recently noticed, is the contraction of the ciliary muscle, which regulates the accommodating power of the organ. Credit is especially due to Dr. T. A. Robertson, of Edinburgh, for calling attention to this influence of the calabar bean. (*Ed. Med. Journ.*, March, 1863, p. 815.) By this influence on the accommodation of the eye, distant objects become indistinct, are apparently magnified, and seem nearer; and Dr. Robertson noticed that this effect was produced sooner and ceased sooner than that upon the pupil. The eye in its normal state thus becomes near-sighted under the influence of the bean. In both these respects there is a strong contrast between the actions of the calabar bean and belladonna; one being exactly antagonistic of the other; as belladonna produces dilatation of the pupil, probably by relaxing the contractile power from the cerebral centres, and at the same time relaxes the ciliary muscles. It does not follow that the operation of the bean is positively stimulant any more upon the ciliary muscles than upon the contractile muscles of the iris. It may in both cases be considered as diminishing or paralyzing a power which in the normal state balances the stimulant influence of the brain. The practical application of these properties of the calabar bean is obvious; and it is now considerably used whenever the indication is presented either for producing contraction of the pupil, or increasing the power of accommodation of the eye to distances.

Therapeutic Use. In regard to the general therapeutic application of the calabar bean little has been decidedly determined. From its extraordinary sedative influence on the spine it would seem to be indicated in all cases of abnormal excitement or irritation of the spinal marrow, especially in tetanus and the poisonous effects of strychnia. Even in the earlier stages of paralysis induced by active congestion or irritation of the spinal marrow, its depressing influence on the cord is obviously called for. Facts have not yet been sufficiently accumulated to justify a positive statement as to its therapeutic virtues. Yet reports are favourable as to its powers in tetanus. Dr. Fraser reports eleven cases in which the calabar bean was used; and of these only two ended fatally. (*Am. Journ. of Med. Sci.*, Oct. 1868, p. 563.)

The bean may be used in the form of tincture or alcoholic extract. The dose of the kernel would be two or three grains, to begin with, and increased if necessary. But it is seldom used in this way. A strong tincture may be made by percolation with alcohol, of which five minims shall represent three grains of the bean, and a tincture of this strength is recommended by Dr. Fraser. The same writer obtained about 4 per cent. of extract by exhausting the kernel with alcohol. The dose, therefore, of alcoholic extract should not exceed one-twenty fourth of that of the kernel, or one-eighth of a grain. In tetanus, Dr. Fraser recommends the alcoholic extract, either in pill or dissolved in diluted alcohol, in the proportion of 32 grains to the fluidounce. He advises that the treatment should be commenced by subcutaneous injection with one-third of a grain, repeated every two hours, until the system is decidedly affected, and then to administer the remedy in three times the dose by the mouth. (*Am. Journ. of Med. Sci.*, Oct. 1868, p. 563.) The Br. Pharmacopœia directs an alcoholic extract, of which the dose is from one-sixteenth to one-fourth of a grain.

For application to the eye Dr. Robertson employed an alcoholic extract mixed with water so as to make liquid preparations of different strengths, one minim representing half a grain, two grains, or four grains. He found these to begin to affect the power of accommodation in 10 minutes, and to produce the full effect in 20 or 30 minutes. They were also wholly unirritating to the eye. They did not, however, keep well, and he afterwards abandoned them for preparations made by suspending the extract in simple syrup. But it would seem best to keep the extract perfectly dry, and mix it with a little water when wanted. This extract dissolves freely in glycerin; and a solution of two and a half grains in 100 minims of that liquid perfectly pure has been found to answer in practice. (*Pharm. Journ.*, July, 1863, p. 26.) Another method of application is to impregnate paper by immersing it three or four times in a concentrated tincture of the bean, allowing it to dry after each immersion, and placing within the lower lid a piece of the paper thus prepared, about one-eighth of an inch square.

PHYTOLACCÆ RADIX. *U. S. Secondary.*

Poke Root.

The root of Phytolacca decandra. *U. S.*

PHYTOLACCA. *Sex. Syst.* Decandria Decagynia.—*Nat. Ord.* Phytolaccaceæ. *Gen. Ch. Calyx* none. *Petals* five, calycine. *Berry* superior, ten-celled, ten-seeded. *Willd.*

Phytolacca decandra. Willd. *Sp. Plant.* ii. 822; Bigelow, *Am. Med. Bot.* i. 39; Barton, *Med. Bot.* ii. 213. This is an indigenous plant, with a large perennial root, often five or six inches in diameter, divided into two or three prin-

cipal branches, soft, fleshy, fibrous, whitish within, and covered with a brownish cuticle. The stems, which are annual, frequently grow to the height of six or eight feet, and divide into numerous spreading branches. They are round, very smooth, green when young, but purple after the berries have ripened. The leaves are scattered, ovate-oblong, entire, pointed, smooth, ribbed beneath, and on short footstalks. The flowers are numerous, small, and in long racemes, which are sometimes erect, sometimes drooping. The corolla consists of five ovate, concave, whitish petals, folding inwards. The germ is green. There are ten stamens, and the same number of pistils. The raceme of flowers becomes a cluster of dark purple, almost black, shining berries, flattened above and below, and divided into ten cells, each containing one seed.

The poke is abundant in all parts of the United States, flourishing along fences, by the borders of woods, and especially in newly cleared and uncultivated fields. It also grows spontaneously in the north of Africa and the south of Europe, where, however, it is supposed to have been introduced from America Its flowers begin to appear in July, and the fruit ripens in autumn. The magnitude of the poke-weed, its large rich leaves, and its beautiful clusters of purple berries, often mingled upon the same branch with the green unripe fruit, and the flowers still in bloom, render it one of the most striking of our native plants. The young shoots are much used as food early in the spring, boiled in the manner of spinage. The ashes of the stems and leaves contain a very large proportion of potassa, yielding, according to Braconnot, not less than 42 per cent. of the pure caustic alkali. In the plant the potassa is neutralized by an acid closely resembling the malic, though differing from it in some respects. The leaves, berries, and root are used, but the two latter only are mentioned in the Pharmacopœia. The root is most active. It should be dug up late in November, cut into thin transverse slices, and dried with a moderate heat. As its virtues are diminished by keeping, a new supply should be procured every year. The berries should be collected when perfectly ripe, and the leaves about the middle of summer, when the footstalks begin to redden.

The *berries* contain a succulent pulp, and yield upon pressure a large quantity of fine purplish-red juice. They have a sweetish, nauseous, slightly acrid taste, with little odour. The colouring principle is evanescent, and cannot be applied to useful purposes in dyeing, from the difficulty of fixing it. Alkalies render it yellow; but the original colour is restored by acids. The juice contains saccharine matter, and, after fermenting, yields alcohol by distillation.

The *dried root* is of a light yellowish-brown colour externally, very much wrinkled, and, when in transverse slices, exhibits on the cut surface numerous concentric rings, formed by the projecting ends of fibres, between which the intervening matter has shrunk in drying. The structure internally in the older roots is firm and almost ligneous; the colour yellowish-white, alternating with darker circular layers. There is no smell. The taste is slightly sweetish, and at first mild, but followed by a sense of acrimony. The active matter is imparted to boiling water and alcohol. From the analysis of Mr. Edward Donnelly, the root appears to contain tannic acid, starch, gum, sugar, resin, fixed oil, and lignin, besides various inorganic substances. (*Am. Journ. of Pharm.*, xv. 169.)

Medical Properties and Uses. Poke is emetic, purgative, and somewhat narcotic. As an emetic it is very slow in its operation, frequently not beginning to vomit in less than one or two hours after it has been taken, and then continuing to act for a long time upon both the stomach and bowels. The vomiting produced by it is said not to be attended with much pain or spasm; but narcotic effects have been observed by some physicians, such as drowsiness, vertigo, and dimness of vision. In overdoses it produces excessive vomiting and purging, attended with great prostration of strength, and sometimes with convulsions. A case is recorded in the *Stethoscope* for March, 1852 (ii. 134), by Dr. Geo. F. Terrill, of Hanover Co., Va., in which death was produced in a woman by eating a double handful of the berries. Free purgation followed upon the first day, after which coma set in, with great prostration, though death did not occur until

after the sixth day. Dr. A. W. Griggs, of West Point, Georgia, has reported the case of a child, six years old, who, after having swallowed two or three fluidrachms of a tincture of the root, was seized in less than an hour with tonic spasm of the muscles; the extremities being stiff, the hands clenched, the feet extended and toes flexed, and the trunk in a condition of opisthotonos. Under the application of cups to the head and spine, cold to the scalp, and a sinapism over the spine, the spasms were relieved, and recovery took place. (*N. Orleans Med. and Surg. Journ.*, A. D. 1866, xix. 255; from *Atlanta Med. and Surg. Journ.*, July, 1866.) If there was no other cause to which these symptoms could be ascribed, poke root must be considered as having before unsuspected powers; for, though considered narcotic, we have seen no proof from any other source that it is a spinal irritant. Poke root has been proposed as a substitute for ipecacuanha; but the slowness and long continuance of its action, and its tendency to purge, wholly unfit it for the purpose. In small doses it acts as an alterative, and has been highly recommended in the treatment of chronic rheumatism. Dr. C. S. Fenner, of Memphis, Tennessee, has found it highly useful, as an internal remedy, in granular conjunctivitis, especially in preventing the relapses to which the affection is so liable. The dose of the powdered root, as an emetic, is from ten to thirty grains; as an alterative, from one to five grains. A saturated tincture of the berries may be given in rheumatic cases, in the dose of a fluidrachm, three times a day. Dr. Fenner uses a saturated decoction, of which he gives a wineglassful every two or three hours. A strong infusion of the leaves or root has been recommended in piles. An ointment, prepared by mixing a drachm of the powdered root or leaves with an ounce of lard, has been used with advantage in psora, tinea capitis, and some other forms of cutaneous disease. Dr. H. G. Carey, of Dayton, Ohio, has cured three cases of sycosis, and one of favus, by the local use of a decoction of the root. (*Va. Med. Journ.*, Aug. 1856, p. 144.) It occasions at first a sense of heat and smarting in the part to which it is applied. An extract made by evaporating the expressed juice of the recent leaves has been used for the same purposes, and acquired at one time considerable repute as a remedy in cancer W.

Myrtus Pimenta. Willd. *Sp. Plant.* ii. 973; Woodv. *Med. Bot.* p. 541, t. 194. — *Eugenia Pimenta.* De Cand. *Prodrom.* iii. 285; Lindley, *Flor. Med.* p. 76. This is a beautiful tree, about thirty feet high, with a straight trunk, much branched above, and covered with a very smooth gray bark. Its dense and ever-verdant foliage gives it at all times a refreshing appearance. The leaves, which are petiolate, vary in shape and size; but are usually about four inches long, elliptical, entire, blunt or obtusely pointed, veined, and of a deep shining green colour. The flowers are small, without show, and disposed in panicles upon trichotomous stalks, which usually terminate the branches. The fruit is a spherical berry, crowned with the persistent calyx, and when ripe is smooth, shining, and of a black or dark-purple colour. The tree exhales an aromatic fragrance, especially during the summer months, when in flower.

It is a native of the West Indies, Mexico, and South America, and is abundant in Jamaica, whence its fruit received the name of *Jamaica pepper*. The berries are the officinal part. They are gathered after having attained their full size, but while yet green, and are carefully dried in the sun. When sufficiently dry, they are put into bags and casks for exportation.

Properties. The berries, as they reach us, are of different sizes, usually about as large as a small pea, round, wrinkled, umbilicate at the summit, of a brownish colour, and when broken present two cells, each containing a black hemispherical seed. They have a fragrant odour, thought to resemble that of a mixture of cinnamon, cloves, and nutmeg. Hence the name of *allspice*, by which they are best known in this country. Their taste is warm, aromatic, pungent, and slightly astringent. They impart their flavour to water, and all their virtues to alcohol. The infusion is of a brown colour, and reddens litmus paper. They yield a volatile oil by distillation. (See *Oleum Pimentæ.*) Bonastre obtained from them a volatile oil, a green fixed oil, a fatty substance in yellowish flakes, tannin, gum, resin, uncrystallizable sugar, colouring matter, malic and gallic acids, saline matters, moisture, and lignin. The green oil has the burning aromatic taste of pimento, and is supposed to be the acrid principle. Upon this, therefore, together with the volatile oil, the medical properties of the berries depend; and, as these two principles exist most largely in the shell or cortical portion, this part is most efficient. According to Bonastre, the shell contains 10 per cent. of the volatile, and 8 of the fixed oil, the seeds only 5 per cent. of the former, and 2·5 of the latter. Berzelius considers the green fixed oil of Bonastre as a mixture of volatile oil, resin, fixed oil, and perhaps a little chlorophyll.

Medical Properties and Uses. Pimento is a warm, aromatic stimulant, used in medicine chiefly as an adjuvant to tonics and purgatives, the taste of which it serves to cover; while it increases their warmth, and renders them more acceptable to the stomach. It is particularly useful in cases attended with much flatulence. It is, however, much more largely employed as a condiment than as a medicine. The dose is from ten to forty grains. A tincture of pimento has been recommended as a local application in chilblains.

Piper nigrum. Willd *Sp. Plant.* i. 159; Woodv. *Med. Bot.* p. 721, t. 246; Carson, *Illust of Med. Bot.* ii. 38, pl. 83. The pepper vine is a perennial plant, with a round, smooth, woody, articulated stem, swelling near the joints, branched, and from eight to twelve feet or more in length. The leaves are entire, broad-ovate, acuminate, seven-nerved, coriaceous, very smooth, of a dark-green colour, and attached by strong sheath-like footstalks to the joints of the branches. The flowers are small, whitish, sessile, covering thickly a cylindrical spadix, and succeeded by globular berries, which are red when ripe.

The plant grows wild in Cochin-China and various parts of India. It is cultivated on the coast of Malabar, in the peninsula of Malacca, in Siam, Sumatra, Java, Borneo, the Philippines, and many other places in the East. The best pepper is said to be produced in Malabar; but Europe and America derive their chief supplies from Sumatra and Java. It appears to have been introduced into the West Indies; as a specimen of black pepper was seen by the author, at the International Exhibition in London, in 1862, among the products of Trinidad. The plant is propagated by cuttings, and is supported by props, or trees planted for the purpose, upon which it is trained. In three or four years from the period of planting, it begins to bear fruit. The berries are gathered before they are all perfectly ripe, and, upon being dried, become black and wrinkled.

White pepper is the ripe berry, deprived of its skin by maceration in water and subsequent friction, and afterwards dried in the sun. It has less of the peculiar virtues of the spice than the black pepper, and is seldom employed.

Properties. The dried berries are about as large as a small pea, externally blackish and wrinkled, internally whitish, of an aromatic smell, and a hot, pungent, almost fiery taste. They yield their virtues partially to water, entirely to alcohol and ether. Pelletier found them to contain a peculiar crystalline matter called piperin, an acrid concrete oil or soft resin of a green colour, a balsamic volatile oil, a coloured gummy substance, an extractive matter like that found in leguminous plants capable of being precipitated by infusion of galls, starch, a portion of bassorin, tartaric and malic acids, lignin, and various salts. *Piperin* was discovered by Professor Œrsted, of Copenhagen, who considered it an organic alkali, and the active principle of pepper. Pelletier, however, utterly denied its alkaline nature and medical activity, and ascribed all the effects, supposed to have been obtained from it, to a portion of the acrid concrete oil with which it is mixed when not very carefully prepared. When perfectly pure, piperin is in colourless transparent crystals, according to Pelletier without taste, fusible at 212°, capable of being sublimed under favourable circumstances in perfect crystals (Waddington, *Pharm. J. and Trans.*, March, 1868, p. 415), insoluble in cold water, slightly soluble in boiling water which deposits it upon cooling, soluble in alcohol, ether, and acetic acid, decomposed by the concentrated mineral acids, with the sulphuric becoming of a blood-red colour, with the nitric, first of a greenish-yellow, then orange, and ultimately red. Christison, however, states in his Dispensatory, that the whitest crystals he had been able to obtain were still acrid, and emitted an irritating vapour when thrown on heated iron. As ordinarily procured the crystals are yellow. Piperin consists of carbon, hydrogen, nitrogen, and oxygen; and its formula, according to Wertheim, is $C_{70}H_{37}N_2O_{10}$.* It is obtained by treating pepper with alcohol, evaporating the tincture to the consistence of an extract, submitting the extract to the action of an alkaline solution by which the oleaginous matter is converted into soap, washing the undissolved portion with cold water, separating the liquid by filtration, treating the matter left on the filter with alcohol, and allowing the solution thus obtained to evaporate spontaneously, or by a gentle heat. Crystals of piperin are deposited, and may be purified by alternate solution in alcohol or ether, and crystallization The taste and medicinal activity of pepper probably depend mainly on the concrete oil or resin, and on the volatile oil. The concrete oil is of a deep-green colour, very acrid, and soluble in alcohol and ether. The volatile oil is limpid, colourless, becoming yellow by age, of a strong odour, and of a taste less acrid than that of pepper itself. It consists of ten eqs. of carbon and eight of hydrogen, and forms a liquid, but not a concrete compound with muriatic acid.

Medical Properties and Uses. Black pepper is a warm carminative stimulant, capable of producing general arterial excitement, but acting with greater proportional energy on the part to which it is applied. From the time of Hippocrates it has been employed as a condiment and medicine. Its chief medicinal

* An interesting chemical investigation into the nature of piperin has been made by Wertheim, the result of which is that it probably consists of a volatile alkaline principle ($C_{12}H_7N$), combined with an electro-negative compound ($C_{58}H_{30}NO_{10}$), which, however, is thus far hypothetical. The former is obtained by distilling piperin mixed with soda and hydrate of lime, at a temperature between 300° and 320°. It is considered by Wertheim as identical with *picolin*, previously obtained by Dr. Anderson from the reaction of nitric acid on piperin, and described by him in a paper presented at the meeting of the British Association, at Edinburgh, in 1850. (*Chem. Gaz.*, Aug. 1849, p. 309; from *Liebig's Annalen.*) M. Cahours has since repeated the experiments of Wertheim, and obtained the same alkaline principle, which he names *piperidin*, and of which he gives the formula $C_{10}H_{11}N$, since changed by Wertheim to $C_{12}H_{13}N$. According to M. Cahours, it is a colourless liquid, having a mixed odour of ammonia and pepper, a very caustic taste, and a strong alkaline action. It is soluble in water in all proportions, and forms crystallizable salts with several acids. (*Ibid.*, May 1, 1852, p. 167.) When piperin is heated with potassa, it yields, among other products, a peculiar acid, which has received the name of *piperic acid.* (*Chem. Gaz.*, Jan. 1, 1858, p. 7.)

In the *Pharmaceutical Journal* (June, 1860, p. 605) is a description by Mr. Evans of the microscopic structure of pepper, to which it may possibly be desirable to recur in instances of supposed adulteration.

application is to excite the languid stomach and correct flatulence. It was long since occasionally administered for the cure of intermittents; but its employment for this purpose had passed from the profession to the vulgar, till a few years since revived by an Italian physician, to be again consigned to forgetfulness. Piperin has also been employed in the same complaint, and has even been thought superior to sulphate of quinia; but experience has not confirmed this favourable opinion. That, in its impure state, when mixed with a portion of the acrid principle, it will occasionally cure intermittents, there can be no doubt; but it is not comparable to the preparations of bark, and is probably less active than the alcoholic extract of pepper. In intermittent fever, when the stomach is not duly susceptible to the action of quinia, as sometimes in drunkards, pepper may be found a useful adjuvant to the more powerful febrifuge. The dose of pepper is from five to twenty grains. It may be given whole or in powder; but is more energetic in the latter state. Piperin has been given in doses varying from one to six or eight grains.

Piper longum, though no longer officinal, deserves a brief notice here, if for nothing else, on account of its former position in medicine. This species of Piper differs from its congeners in having its lower leaves cordate, petiolate, seven-nerved, its upper oblong-cordate, sessile, and five-nerved; its flowers in dense, short, terminal, and nearly cylindrical spikes; and its fruit, consisting of very small one-seeded berries or grains, embedded in a pulpy matter. It is a native of Southeastern Asia, and is produced abundantly in Bengal and other parts of Hindostan. The fruit is green when immature, and becomes red as it ripens. It is gathered in the former state, as it is then hotter than when perfectly ripe. The whole spike is taken from the plant, and dried in the sun. *Long pepper*, as the fruit is called, is cylindrical, an inch or more in length, indented on its surface, of a dark-gray colour, a weak aromatic odour, and a pungent fiery taste. M. Dulong found its chemical composition to be closely analogous to that of black pepper. Like that it contains *piperin*, a concrete oil or soft resin upon which its burning acrimony depends, and a volatile oil to which it probably owes its odour. Its medical virtues are essentially the same as those of black pepper; but it is considered inferior to that spice, and is seldom used.

The prepared concrete juice of Abies excelsa. *U. S.* A resinous exudation from the stem of the Spruce Fir, Abies excelsa. *Br.*

Poix de Bourgogne, Poix jaune, Poix blanche, *Fr.;* Burgundisches Pech, *Germ.*

The genus Pinus of Linnæus has been divided into three genera, viz., *Pinus*, *Abies*, and *Larix:* the first including the pines, the second the firs and spruces, and the third the larches; and the division is recognised in this work.

Abies. *Sex. Syst.* Monœcia Monadelphia. — *Nat. Ord.* Pinaceæ or Coniferæ.

Gen. Ch. Male flowers. *Catkins* solitary, not racemose; *Scales* staminiferous at the apex. *Stamens* two, with one-celled anthers. Females. *Catkins* simple. *Ovaries* two. *Stigmas* glandular. *Cone* with imbricated scales, which are thin at the apex, and rounded. *Cotyledons* digitate-partite. *Leaves* solitary in each sheath. *De Cand.*

Abies excelsa. De Candolle. — *A. communis.* Loudon's *Encyc. of Plants.* — *Pinus Abies.* Willd. *Sp. Plant.* iv. 506; Woodv. *Med. Bot.* p. 4, t. 2. The *Norway spruce* is a very lofty tree, rising sometimes one hundred and fifty feet in height, with a trunk from three to five feet in diameter. The leaves, which stand thickly upon the branches, are short, obscurely four-cornered, often curved, of a dusky-green colour, and shining on the upper surface. The male aments are purple and axillary, the female of the same colour, but usually terminal. The fruit is in pendent, purple, nearly cylindrical strobiles, the scales of which are oval, pointed, and ragged at the edges.

This tree is a native of Europe and Northern Asia. Though designated as the source of Burgundy pitch, it furnishes but a part of the substance sold under that name by the druggists. Tingley asserts that the real Burgundy pitch is obtained from the *Abies picea*, or European silver fir tree. According to Geiger, who is probably correct, it is procured from both species. To obtain the *pitch*, portions of the bark are removed so as to lay bare the wood, and the flakes of concrete resinous matter which form upon the surface of the wound, having been detached by iron instruments, are melted with water in large boilers, and then strained through coarse cloths. It is called Burgundy pitch from the province of that name in the east of France. We are told that the greater portion is collected in the neighbourhood of Neufchâtel. According to Mr. Daniel Hanbury, however, it is no longer brought from Switzerland, being supplied to commerce partly from Baden and Austria in Germany, and partly from Finland, where it is largely produced. (*Chem. News*, Oct. 4, 1867, p. 181.)

From various species of pine, in different parts of Europe, a similar product is obtained and sold by the same name. It is prepared by removing the juice which concretes upon the bark of the tree, or upon the surface of incisions, called *galipot* by the French, and purifying it by melting, and straining either through cloth or a layer of straw. A *factitious Burgundy pitch* is made by melting together common pitch, rosin, and turpentine, and agitating the mixture with water, which gives it the requisite yellowish colour. Its odour is different from that of the genuine. Mr. Hanbury gives as a test of true Burgundy pitch that it is almost entirely soluble in twice its weight of glacial acetic acid, while the factitious similarly treated forms a turbid mixture, which quickly separates into a thick oily liquid above, and a bright solution below. (*Ibid., loc. citat.*)

As brought to this country, Burgundy pitch is generally mixed with impurities, which require that it should be melted and strained before being used. In its pure state it is hard, brittle, quite opaque, of a yellowish or brownish-yellow colour, and a weak terebinthinate taste and odour. It is very fusible, and at the heat of the body softens and becomes adhesive. It differs from turpentine in containing a smaller proportion of volatile oil.

Medical Properties and Uses. Applied to the skin in the shape of a plaster, Burgundy pitch acts as a gentle rubefacient, producing a slight inflammation and serous effusion without separating the cuticle. Sometimes it excites a papillary or vesicular eruption; and we have known it to act upon the surface as a violent poison, giving rise to severe pain, swelling, and redness, followed by vesication and even ulceration. It is used chiefly in chronic rheumatic pains, and in chronic affections of the chest or abdomen, which call for a gentle but long-continued revulsion to the skin. A plaster of Burgundy pitch has been found very useful in malignant pustules (*Ann. de Thérap.*, A. D. 1860, p. 103.)

PIX CANADENSIS. *U. S.*

Canada Pitch.

The prepared concrete juice of Abies Canadensis. *U. S.*

ABIES. See PIX BURGUNDICA.

Abies Canadensis. Michaux, *N. Am. Sylv.* iii. 185. — *Pinus Canadensis.* Willd. *Sp. Plant.* iv. 505. This is the *hemlock spruce* of the United States and Canada. When of full growth it is often seventy or eighty feet high, with a trunk two or three feet in diameter, and of nearly uniform dimensions for two-thirds of its length. The branches are slender, and dependent at their extremities. The leaves are very numerous, six or eight lines long, flat, denticulate, and irregularly arranged in two rows. The strobiles are ovate, little longer than the leaves, terminal, and pendulous.

The tree is abundant in Canada, Nova Scotia, and the more northern parts

of New England; and is found in the elevated and mountainous regions of the Middle States. Its bark abounds in the astringent principle, and is much used for tanning in the northern parts of the United States. An extract is made from the bark for tanning, which is prepared by evaporation in vacuo, and is said by Mr. N. Spence Thomas, who prepares it, to have a close resemblance to extract of rhatany, and is proposed by him as a medicine applicable to similar purposes. It no doubt contains tannic acid largely. (*Am. Journ. of Pharm.*, May, 1866, p. 214.) The tree contains much less juice than some other of the Pinaceæ; and very little flows from incisions made into its trunk. But in the trees which have attained their full growth, and are about or have begun to decay, the juice exudes spontaneously, and hardens upon the bark, in consequence of the partial evaporation or oxidation of its volatile oil. The bark thus encrusted is stripped from the tree, broken into pieces and boiled in water. The pitch melts, rises to the surface, is skimmed off, and is still further purified by a second boiling in water. It is brought to Philadelphia from the north of Pennsylvania, in dark-coloured brittle masses, which, on being broken, exhibit numerous minute fragments of bark interspersed through their substance. From these it is purified in the shops, by melting and straining through linen or canvas. (Ellis, *Journ. of Phil. Col. of Pharm.*, ii. 18.) Another mode of collecting it is to make incisions into the body of the tree, and to remove the juice as it exudes. (Stearns, *Am. Journ. of Pharm.*, Jan. 1860, p. 29.)

Thus prepared it is hard, brittle, quite opaque, of a dark yellowish-brown colour, becoming still darker by exposure to the air, of a weak peculiar odour, and scarcely any taste. It softens and becomes adhesive with a moderate heat, and melts at 198° F. Its constituents are resin and a minute proportion of volatile oil. It is commonly known by the incorrect name of *hemlock gum*.

Medical Properties and Uses. Canada pitch is a gentle rubefacient, closely analogous to Burgundy pitch in its properties, and employed for precisely the same purposes. It is, however, more readily softened by heat, and is sometimes almost too soft for convenient application at the temperature of the body. A volatile oil obtained from Abies Canadensis, and called *oil of spruce*, or *oil of hemlock*, has been employed to produce abortion, with the effect of endangering the life of the female. (J. S. Paige, *N. Y. Journ. of Med.*, viii. 184.)

PIX LIQUIDA. *U. S., Br.*

Tar.

The impure turpentine procured by burning from the wood of Pinus palustris and of other species of Pinus. *U. S.* A bituminous liquid, obtained from the wood of Pinus sylvestris and other Pines, by destructive distillation. *Br.*

Goudron, *Fr.;* Theer, *Germ.;* Pece liquida, *Ital.;* Alquitran, *Span.*

The tar used in this country is prepared from the wood of various species of pine, particularly *Pinus palustris* of the Southern States. (See *Terebinthina.*) The dead wood is usually selected, because, when vegetation ceases, the resinous matter becomes concentrated in the interior layers. The wood is cut into billets of a convenient size, which are placed together so as to form a large stack or pile, and then covered with earth as in the process for making charcoal. The stack is built upon a small circular mound of earth previously prepared, the summit of which gradually declines from the circumference to the centre, where a cavity is formed, communicating by a conduit with a shallow ditch surrounding the mound. Fire is applied through an opening in the top of the pile, and a slow combustion is maintained, so that the resinous matter may be melted by the heat. This runs into the cavity in the centre of the mound, and passes thence by the conduit into the ditch, whence it is transferred into barrels. Immense quantities of tar are thus prepared in North Carolina and the south-eastern parts of Virginia, sufficient, after supplying our own consumption, to afford a large surplus for exportation. Considerable quantities of tar have been

prepared also in the lower parts of New Jersey, in some portions of New England, and in Pennsylvania west of the Alleghany mountains, from the *Pinus rigida*, or pitch pine, and perhaps from some other species.

Properties. Tar has a peculiar empyreumatic odour, a bitterish, resinous, somewhat acrid taste, a colour almost black, and a tenacious consistence intermediate between that of a liquid and solid. It consists of resinous matter, united with acetic acid, oil of turpentine, and various volatile empyreumatic products, and coloured with charcoal. By distillation it yields an acid liquor called *pyroligneous acid* (see *Acidum Aceticum*), and an empyreumatic oil called *oil of tar;* and what is left behind is *pitch.* The empyreumatic oil has been ascertained by Dr. Reichenbach, of Moravia, to contain, besides oil of turpentine, six distinct principles, which he has named *paraffin*, *eupion*, *creasote*, *picamar*, *capnomor*, and *pittacal.* Of these, only picamar and creasote merit particular attention; the former as the principle to which tar owes its bitterness, the latter as the one upon which it probably depends chiefly for its medical virtues (See *Creasotum.*) Tar yields a small proportion of its constituents to water, which is thus rendered medicinal, and is employed under the name of *tar water.* It is dissolved by alcohol, ether, and the volatile and fixed oils.

The pitch, left after the evaporation of tar, was formerly officinal, with the British Colleges, under the names of *Pix nigra*, *Pix arida*, or simply *Pix*, but has been omitted in the present British Pharmacopœia. It has a shining fracture, softens and becomes adhesive with a moderate heat, melts in boiling water, and consists of the resin of the pine unaltered, and of various empyreumatic resinous products which have received the name of *pyretin.* (Berzelius, *Trait. de Chim.*, vi. 641 and 680.) It appears to be very gently stimulant or tonic, and has been used internally in ichthyosis and other cutaneous diseases, and recently with great advantage in piles. The dose is from ten grains to a drachm given in pills. Pitch is also used externally in the form of ointment.

Medical Properties and Uses. The medical properties of tar are similar to those of the turpentines. It is occasionally used with advantage in chronic catarrhal affections, and complaints of the urinary passages. Little benefit can be expected from it in genuine phthisis, in the treatment of which it was formerly recommended. Dr. Bateman employed it advantageously as an internal remedy in ichthyosis. It has also been used advantageously, in the same way, in the form of tar-water for the cure and prevention of furuncles. Its vapour, inhaled into the lungs, has been found serviceable in numerous cases of bronchial disease. Its effects in this way are most conveniently obtained by placing a cup containing tar or oil of tar in a small water-bath, over a common nurse-lamp, and thus impregnating the air of the chamber. Externally applied, in the state of ointment, tar is a very efficient remedy in tinea capitis or scaldhead, and in some cases of psoriasis; and has been used with advantage in foul or indolent ulcers, and some other affections of the skin. Some prefer for the same purpose a mixture of glycerin and tar.*

It may be used in the form of tar-water (see *Infusum Picis Liquidæ*), or in substance made into pills with wheat flour, or mixed with sugar in the form of an electuary. The dose is from half a drachm to a drachm, and may be repeated so as to amount to three or four drachms daily.†

Off. Prep. Infusum Picis Liquidæ, *U. S.;* Unguentum Picis Liquidæ. W.

* *Glycerated Tar.* The following formula has been recommended. Take of *tar* and *glycerin*, each, six troyounces, and of *starch*, in powder, two drachms. Mix the starch thoroughly with the glycerin previously warmed, then add the tar, and heat quickly to 212°. Strain if necessary, and stir the mixture while cooling. (*Pharm. Journ.*, Sept. 1862.)

† *Tar Beer or Wine of Tar.* A preparation under this name has been used to some extent in Philadelphia in pulmonary affections. The following is the formula recommended by Prof. Procter. Take of *ground malt*, *honey*, and *tar*, each, a pound; *yeast* half a pint. Mix the malt and honey with six pints of water in an earthen vessel; keep the mixture for three hours, with occasional stirring, at the temperature of 150° F., then allow it to cool to 80°, and add the yeast. Sustain the fermentation for 36 hours by a heat between 70° and 80°, then decant the supernatant liquid, add the tar gradually to the dregs, stir-

PLUMBUM.

Lead.

Plomb, *Fr.;* Blei, *Germ.;* Lood, *Dutch;* Piombo, *Ital.;* Plomo, *Span.;* Chumbo, *Port.*

Lead is not officinal in its metallic state, but enters into a number of important medicinal preparations. It occurs in nature as an oxide, as a sulphuret called *galena*, and in saline combination, forming the native sulphate, phosphate, carbonate, chromate, molybdate, tungstate, and arseniate of lead. The oxide is rare, but galena is exceedingly abundant, and is the ore from which nearly all the lead of commerce is extracted. The process of extraction consists in melting the ore in contact with charcoal. The richest and most extensive mines of galena are found in this country. The lead region of the United States extends in length from the Wisconsin in the north to the Red River of Arkansas in the south, and in breadth about one hundred and fifty miles.

Properties. Lead is a soft, bluish-gray, and very malleable metal, presenting a bright surface when newly melted or cut. It has a perceptible taste, and a peculiar smell when rubbed. It undergoes but little change in the air, but is acted on by the combined influence of air and rain-water, which give rise to a hydrated protoxide, which is afterwards changed, in part, into carbonate, by absorbing carbonic acid from the atmosphere; and if in water, the carbonate is imparted to it in the state of bicarbonate, which renders the liquid poisonous. This chemical effect on the metal is greater in proportion as the water is purer. (See *page* 137.) Aqueous vapour passed through leaden pipes has a similar corroding effect, which is greater as the lead is purer. (*Am. Journ. of Pharm.*, Nov. 1863, p. 507.) Spring and river water act on lead differently; the lead becoming slowly oxidized, and covering itself with a black coating of suboxide, which adheres strongly to the metal, and thus in some measure protects the water. (Langlois, *Journ. de Pharm. et de Chim.*, 4e sér., ii. 29.) M. Stalmann has satisfied himself by experiment, that an extremely minute quantity of ammonia or of nitric acid will very much promote the action of water upon lead; a millionth of ammonia being sufficient for the purpose. (*Ibid.*, iv. 467.) Metallic lead seems to be liable to the attacks of certain insects, which bore into and sometimes through it, not using it as food, but apparently in search of secure places of retreat for future development. A knowledge of this fact may sometimes be important. (*Am. Journ. of Pharm.*, Jan. 1865, p. 72.) Its sp. gr. is 11·4, melting point about 612°, and eq. 103·5. Exposed to a stream of oxygen on ignited charcoal, it burns with a blue flame, throwing off dense yellow fumes. The best solvent of lead is nitric acid; but the presence of sulphuric acid destroys, and that of muriatic acid lessens its solvent power, on account of the insolubility of the sulphate and chloride of lead. Lead forms five oxides, a dioxide, protoxide, sesquioxide, deutoxide, and red oxide. The *dioxide* consists of two equivalents of lead and one of oxygen. The *protoxide*, called in commerce *massicot*, may be obtained by calcining, in a platinum crucible, the subnitrate of lead, formed by precipitating a solution of the nitrate by ammonia. On a large scale it is manufactured by exposing melted lead to the action of the air. Its surface becomes encrusted with a gray pellicle, which, being scraped off, is quickly succeeded by another; and the whole of the metal, being

ring constantly, so as to make a uniform mixture, and return the decanted fluid to the vessel. Stir the whole occasionally for a week, adding water to preserve the measure; then strain with strong expression, allow the expressed liquor to stand until it becomes nearly clear by subsidence, and finally filter through paper. (*Am. Journ. of Pharm.*, xxii. 111.)

A Syrup of Tar is prepared by Mr. Thos. A. Lancaster in the following manner. Take of *tincture of tar* (made in the proportion of two troyounces of tar to a pint of alcohol) f℥ij, *carbonate of magnesia* ℥j or q. s., *white sugar* lbj avoird. Rub the tincture thoroughly with the carbonate; add half a pint of water gradually; then filter, and, when the liquid ceases to pass, pour water into the filter till the product measures half a pint; lastly, add the sugar and dissolve it by means of a gentle heat. The syrup may be given in the dose of half an ounce or an ounce. (*Ibid.*, Nov. 1859, p. 555.)—*Note to the twelfth edition.*

in this way successively presented to the air, becomes converted into a greenish-gray powder, consisting of protoxide and metallic lead. This, by exposure to a moderate heat, absorbs more oxygen, and is converted wholly into protoxide. This oxide has a yellow colour, and is the only oxide of lead capable of forming salts with the acids. It consists of one eq. of lead 103·5, and one of oxygen 8 = 111·5. A variety of the protoxide, called *litharge*, is very much used in pharmacy, and is officinal in all the Pharmacopœias. (See *Plumbi Oxidum.*) The *sesquioxide*, discovered by Winckelblech, is unimportant. The *deutoxide*, called also *puce* oxide from its *flea*-brown colour, may be obtained by treating red lead with nitric acid. The acid takes up the protoxide and leaves the deutoxide, which may be purified by washing with boiling water A more productive process is to precipitate four parts of acetate of lead by three of carbonate of soda, and then to pass into the thin pasty mass of carbonate of lead a stream of chlorine, which converts the protoxide of the carbonate into the brown deutoxide. (*F. Wöhler.*) Solution of chlorinated soda may be conveniently employed to furnish the necessary chlorine. (F. F. Mayer, *Am. Journ. of Pharm.*, Sept. 1856, 410.) Deutoxide of lead is a tasteless powder, of a dark-brown colour. When heated to redness it loses half its oxygen and becomes protoxide. It consists of one eq. of lead 103·5, and two of oxygen 16 = 119·5. The *red oxide*, called in commerce *minium* or *red lead*, is described under another head. (See *Plumbi Oxidum Rubrum.*) Lead combines with iodine, forming the officinal iodide of lead. The acetate, carbonate, and nitrate are also officinal.

The best tests of lead are sulphuretted hydrogen, and a solution of iodide of potassium. The former produces a black precipitate of sulphuret of lead, the latter, a yellow one of iodide of lead.

Medical Properties and Uses. The effects of lead in its various combinations are those of a sedative and astringent. It is used internally for reducing the action of the heart and arteries, and for restraining inordinate discharges; and externally as an abater of inflammation. When introduced into the system in a gradual manner with the food or drinks, or by working in the metal, or when taken in small and frequently repeated doses, it acts injuriously on the nervous system, producing a peculiar colic, called *lead colic*, sometimes apoplectic symptoms, and occasionally palsy, which is almost always partial, and affects for the most part the upper extremities. Amaurosis has sometimes been traced to the poisonous action of lead. In some instances salivation occurs; and, according to Dr. Henry Burton, the constitutional effects of the metal are indicated by a narrow lead-blue line at the edge of the gum, round two or more of the teeth, as a constant and early sign. According to Mialhe, lead gains access to the circulation by means of the chlorides of the alkalifiable metals in the alimentary canal, which form with the lead a soluble double chloride of lead and potassium, or of lead and sodium. The treatment necessary in lead colic is given under *Carbonate of Lead.* Lead palsy is usually attended with dyspepsia, constipation, tendency to colic, lassitude, and gloominess of mind, and is best treated, after the elimination of the lead, by tonics, aperients, exercise, and avoidance of the cause of the disease. The acute poisonous effects of the lead preparations are to be combated by emetics if free vomiting has not previously occurred, by purges of sulphate of magnesia or sulphate of soda, and by opium. These sulphates are supposed to act as antidotes by forming sulphate of lead. It is probable that they lessen the poisonous effects of the soluble salts of lead; but the sulphate, though insoluble in water, may be to some extent soluble in the gastric juice; and, as to its external use in the form of ointment, it has been found by Flandin to prove poisonous to the inferior animals.

For the purpose of eliminating lead from the system, warm sulphuretted baths are useful, formed by dissolving four ounces of sulphuret of potassium in thirty gallons of water, in a wooden tub. These baths cause discoloration of the skin, from the formation of sulphuret of lead, and should be repeated every few days, until this effect ceases to be produced. During each bath, the patient should be

well washed with soap and water with the aid of a flesh-brush, in order to remove the discoloration. By proceeding in this way, the lead on the skin, or in its pores, is rendered insoluble and inert, and at the same time removed. Dr. Melsens praises iodide of potassium as a means of separating lead from the tissues, acting by rendering the metal soluble, and separating it principally by the urine. (See *Potassii Iodidum.*)

Orfila has determined, by experiments on dogs, the appearance exhibited by the mucous membrane of the stomach, after the use of small doses of the salts of lead. After the action of such doses for two hours, dull white points are visible on the membrane, sometimes in rows and sometimes disseminated, and evidently consisting of the metal, united with the organic tissue. If the animal be allowed to live for four days, the same spots may be seen with the magnifier; and if sulphuretted hydrogen be applied to the surface, they are instantly blackened. (*Archives Gén.*, 3e sér., iv. 244.)

According to M. Gendrin, sulphuric acid, prepared like lemonade, and used both internally and externally, is a prophylactic against the poisonous effects of lead, especially the lead colic. It may be supposed to act by forming the comparatively inert sulphate of lead with the poison. Mr. Benson, a manager of white lead works at Birmingham, has tried this acid, and finds it a preventive of lead colic in his establishment, where it was exceedingly prevalent before its employment. He uses it as an addition to ginger beer, to which bicarbonate of soda is also added to render it brisk, but not in sufficient quantity to neutralize the whole of the acid. On the other hand, the powers of sulphuric acid in preventing the poisonous effects of lead are positively denied by Dr. A. Grisolle, Dr. Melsens, and other authorities. Dr. Grisolle recommends that workmen employed in lead manufactories should use frequent baths, avoid intemperance, and always eat before they enter upon their work in the morning. He supposes that, in a great majority of cases, the metal is introduced into the system through the stomach by means of the saliva or food.

According to MM. Sandras and Bouchardat, the hydrated sesquisulphuret of iron acts as an antidote to the salts of lead; and its efficacy has been confirmed by its effects in a case reported by M. Lepage. (*Ann. de Thérap.*, 1857, p. 224.) After acute poisoning by lead, the metal has been found in the liver and brain. Indeed, it may be detected in most of the organs, a long time after the ingestion of the poison.

The following table embraces all the officinal preparations of lead.

Plumbi Oxidum; Lithargyrum, *Br.* 1864. *Oxide of Lead. Litharge.*

Emplastrum Plumbi; Emplastrum Lithargyri, *Br.* 1864. *Lead plaster. Litharge plaster.* This plaster is used as the basis of several other plasters, and enters, through the *soap plaster*, into the *soap cerate* of the U. S. Pharm.

Acetate of Lead. Sugar of Lead.

Saccharum Saturni, Cerussa acetata, *Lat.;* Acétate de plomb, Sucre de plomb, Sel de Saturne, *Fr.;* Essigsaures Bleioxyd, Bleizucker, *Germ.;* Zucchero di Saturno, *Ital.;* Azucar de plomo, *Span.*

In the British Pharmacopœia the following formula is given for preparing this salt. "Take of Oxide of Lead, in fine powder, *twenty-four ounces* [avoirdupois]; Acetic Acid *two pints* [Imperial measure], or *a sufficiency;* Distilled Water *one pint* [Imp. meas.]. Mix the Acetic Acid and the Water, add the Oxide of Lead, and dissolve with the aid of a gentle heat. Filter, evaporate till a pellicle forms, and set aside to crystallize, first adding a little Acetic Acid should the fluid not have a distinctly acid reaction. Drain and dry the crystals on filtering paper, without heat." *Br.* In the U. S. Pharmacopœia the salt is properly placed in the catalogue of the Materia Medica.

Preparation. Acetate of lead is obtained by two methods. By one method, thin plates of lead are placed in shallow vessels filled with distilled vinegar, in such a manner as to have a part of each plate rising above the vinegar; and these are turned from time to time, so as to bring different portions of the metallic surface in contact with the air. The metal, after having become protoxidized, dissolves in the vinegar to saturation, and the solution is evaporated to the point of crystallization. This process is a slow one, but furnishes a salt which is perfectly neutral. The other method consists in dissolving by the assistance of heat, litharge, or the protoxide of lead obtained by calcination, in an excess of distilled vinegar or of purified pyroligneous acid, contained in leaden boilers. The oxide is quickly dissolved, and, when the acid has become saturated, the solution is transferred to other vessels to cool and crystallize. The crystals having formed, the mother-waters are decanted, and, by evaporation, made to yield a new crop. These are generally yellow, but may be rendered white by repeated solutions and crystallizations.

Acetate of lead is extensively manufactured in Germany, Holland, France, and England, as well as in the United States. It is principally consumed in the arts of dyeing and calico-printing, in which it is employed to form with alum the acetate of alumina, to act as a mordant.

Properties. Acetate of lead is a white salt, crystallized in brilliant needles, which have the shape of prisms, terminated by dihedral summits. Its taste is at first sweet and afterwards astringent. Exposed to the air it effloresces slowly. It dissolves in four times its weight of cold, and in a much smaller quantity of boiling water. It is soluble also in alcohol. Its solution in common water is turbid, in consequence of the formation of carbonate of lead with the carbonic acid which such water always contains. This turbidness may be removed by the addition of a small proportion of vinegar, or of dilute acetic acid. In pure distilled water, free from carbonic acid, it ought to dissolve entirely, and form a clear solution. The commercial acetate is sometimes impure from the presence of sulphate and carbonate of lead. In purchasing it the apothecary should select large crystalline masses. Mr. John Mackay analyzed a specimen of this salt, derived from the London market, which contained nearly 30 per cent. of sulphate of lead. (*Pharm. Journ.*, Jan. 1856, p. 316.) Sulphuric acid, when added to a solution of acetate of lead, produces instantly a precipitate of sulphate of lead; and the disengaged acetic acid gives rise to vapours having the smell of vinegar. The salt, when heated, first fuses and parts with its water of crystallization, and afterwards is decomposed, yielding acetic acid and pyroacetic spirit (acetone), and leaving a residue of charcoal and reduced lead. An important property of sugar of lead is its power of dissolving a large quantity of protoxide of lead. (See *Liquor Plumbi Subacetatis.*) It consists of one eq. of acetic acid 51, one of protoxide of lead 111·5, and three of water 27 = 189·5; and its formula is $PbO,C_4H_3O_3+3HO$.

Incompatibles and Tests. Acetate of lead is decomposed by all acids, and by those soluble salts, the acids of which produce with protoxide of lead insoluble or sparingly soluble compounds. Acids of this character are the sulphuric, muriatic, citric, and tartaric. It is also decomposed by lime-water, and by ammonia, potassa, and soda; the last two, if added in excess, dissolving the precipitate at first formed. It is decomposed by hard water, in consequence of the sulphate of lime and common salt which such water usually contains. With sulphuretted hydrogen it gives a black precipitate of sulphuret of lead; with iodide of potassium, a yellow one of iodide of lead; and with a carbonated alkali, a white one of carbonate of lead. "Thirty-eight grains dissolved in water require for complete precipitation 200 grain-measures of the *volumetric solution of oxalic acid.*" *Br.*

Medical Properties and Uses. Acetate of lead, in medicinal doses, is a powerful astringent and sedative; in overdoses, an irritant poison. It has sometimes been given in pretty large doses in regular practice without bad effects; and cases are on record where a quarter of an ounce has been swallowed without proving fatal. On the other hand, it sometimes produces colica pictonum, even when given in medicinal doses. It is proper to remark, however, that the immediate effects of an overdose are often escaped by prompt and spontaneous vomiting; and that the remote constitutional effects are not apt to occur so long as the evacuations from the bowels are not materially diminished. The class of diseases in which acetate of lead has been most frequently used are hemorrhages, particularly from the lungs, stomach, intestines, and uterus. Its effect in restraining the discharge of blood is admitted to be very powerful. It has been employed by Dr. Burkart with supposed benefit in pneumonia, especially in cases occurring in the aged, in which bleeding or antimony cannot be borne. It has also been used with advantage in certain forms of dysentery and diarrhœa, and has been recommended in particular stages of cholera infantum. Combined with opium, it is well suited to the treatment of the diarrhœa occurring in phthisis. It sometimes proves a valuable remedy in checking vomiting. Dr. Irvine, of Charleston, recommended it to compose the irritability of the stomach in yellow fever. Dr. Wood has employed it in several cases of yellow fever, at the beginning of the second stage, with apparently good effect. The dose recommended is two grains every two hours, given steadily until thirty-six grains have been taken. Dr. Wood conceives that the remedy is well suited to obviate the peculiar inflammation of the gastric mucous membrane, and to prevent hemorrhage, either of pure blood, or of altered blood in the form of black vomit. (*Trans. of the College of Phys. of Philad.*, ii. 449.) Dr. Davis, of Columbia, S. C., has used acetate of lead with benefit in the irritable stomach attendant on bilious fever. It has been much extolled by the German practitioners, in the class of fevers attended with ulcerations of the intestines. In some of these cases it was advantageously combined with carbonate of ammonia. The same practitioners have strongly recommended it in aneurism of the aorta, and Dupuytren, on their report of its efficacy, tried it in several cases, and with marked effect in diminishing the size of the aneurismal tumour. Dr. Wood has imitated the practice in aneurism of the aorta, and employed it in several cases of enlarged heart, with encouraging results. In the treatment of the latter disease, the testimony of M. Brachet, of Lyons, is strongly in favour of the remedy. Acetate of lead has been employed by Drs. Neuhold and Hasserbronc, with remarkable success, in strangulated hernia, used in enemata, containing ten grains of the salt dissolved in six fluidounces of tepid water, and repeated every two hours. In mercurial salivation, M. Brachet found it very efficacious, administered in grain pills, night and morning. The solution is frequently used as a collyrium; and, applied by means of cloths, or mixed with crumb of bread, it forms a good application to superficial inflammation. It is sometimes advantageous to associate opium with the solution, in which case the meconate of morphia of the opium is decomposed, with the result of forming acetate of morphia in solution, and meconate of lead which precipitates. A convenient lotion, containing an

excess of acetate of lead, may be formed by adding four grains of the acetate and four of opium to a fluidounce of water.

The practitioner should bear in mind that, when long continued in small doses, this medicine is apt to produce dangerous constitutional effects. These are chiefly of two kinds; 1. an affection of the alimentary canal, attended with severe pain and obstinate constipation, called *colica pictonum*, or *lead colic;* 2. a chronic affection of the muscles, especially of the extensors of the upper extremities, characterized by an excessive wasting of these organs, and denominated *lead palsy*. Both these affections are apt to be produced in those artisans who work in lead. The approach of these dangerous constitutional symptoms is indicated by a narrow lead-blue line at the edge of the gums.

The dose of acetate of lead is from one to three grains, in the form of pill, repeated every two or three hours. It is generally given combined with opium. The solution for external use may be made by dissolving from two to three drachms in a pint of water; and, if it be wanted clear, a fluidrachm of vinegar or of dilute acetic acid may be added, which immediately dissolves the carbonate of lead, to which its turbidness is owing. When the skin is denuded of the cuticle, the solution should be weaker. The usual strength of the solution as a collyrium is from one to two grains to the fluidounce of *distilled* water.

PLUMBI CARBONAS. *U. S., Br.*

Carbonate of Lead. White Lead.

Ceruse; Céruse, Carbonate de plomb, Blanc de plomb, Blanc de céruse, *Fr.;* Bleiweiss, *Germ.;* Cerussa, *Lat., Ital.;* Albayalde, *Span.*

Preparation. Carbonate of lead is prepared by two principal methods. By one method it is obtained by passing a stream of carbonic acid through a solution of subacetate (trisacetate) of lead. The acid combines with the excess of protoxide, and precipitates as carbonate of lead, while a neutral acetate remains in solution. This, by being boiled with a fresh portion of protoxide, is again brought to the state of subacetate, when it is treated with carbonic acid as before. In this way the same portion of acetate repeatedly serves the purpose of being converted into subacetate, and of being decomposed by carbonic acid. The carbonate obtained is washed, dried with a gentle heat, and thrown into commerce. This process, which produces white lead of the first quality, was invented by Thenard, about the year 1802, and is that which is usually pursued in France and Sweden.

A modification of the process of Thenard is now pursued by some manufacturers in England. It consists in mixing litharge with a hundredth part of acetate of lead, and subjecting the mixture, previously moistened with very little water, to a stream of carbonic acid. (*Pelouze.*)

The other method, which consists in exposing lead to the vapours of vinegar, originated in Holland, and is usually pursued in England and the United States; but in England, with some modifications which are not well known. We shall describe this process as pursued by our own manufacturers. The lead is cast into thin sheets, made by pouring the melted lead over an oblong sheet-iron shovel, with a flat bottom, and raised edges on its sides, which is held in a slanting direction over the melting-pot. As many of these sheets are then loosely rolled up as may be sufficient to form a cylinder five or six inches in diameter, and seven or eight high, which is placed in an earthen pot containing about half a pint of vinegar, and having within, a few inches from the bottom, three equidistant projecting portions in the earthenware, on which the cylinder of lead is supported, in order to keep it from contact with the vinegar. The pots thus prepared are placed side by side, in horizontal layers, in a building roughly constructed of boards, with interstices between them. The first layer is covered with boards, on which a stratum of tan or of refuse straw from the stables is

strewed; and fresh layers of pots, boards, and tan or straw are successively placed until the building is filled. The sides are also enclosed with straw. The layers of pots contained in one building, called a stack, are allowed to remain undisturbed for about six weeks, at the end of which time they are unpacked, and the cylinder of sheet-lead in each pot, though still retaining its shape, is found almost entirely converted into a flaky, white, friable substance, which is the white lead. This is separated from the lead yet remaining in the metallic state, ground in water, whereby it is washed and reduced to fine powder, and finally dried in long shallow reservoirs, heated by steam.

Pelouze has succeeded in explaining all these processes on the same general principles. In Thenard's process, it is admitted that the same portion of acetate of lead repeatedly unites with protoxide, and gives it up again to carbonic acid to form the carbonate. In the modified English process, referred to above, he supposes that the one per cent. of acetate of lead combines with sufficient litharge to convert it into subacetate, which immediately returns to the state of neutral acetate, by yielding up its excess of base to form the carbonate with the carbonic acid. The acetate is now ready to combine with a fresh portion of litharge, to be transferred to the carbonic acid as before; and thus this small proportion of acetate, by combining with successive portions of the litharge, finally causes the whole of the latter to unite with the carbonic acid. In the Dutch process, Pelouze has rendered it almost certain, that none of the oxygen or carbonic acid of the carbonate is derived from the vinegar. In this process he supposes that the heat, generated by the fermentation of the tan or straw, volatilizes the vinegar, the acetic acid of which, with the assistance of the oxygen of the air, forms with the lead a small portion of subacetate. This, by reacting with the carbonic acid, resulting from the decomposition of the tan or straw, or derived from the atmosphere, forms carbonate of lead, and is brought to the state of neutral acetate. The neutral acetate returns again to the state of subacetate, and, by alternately combining with and yielding up the protoxide, causes the whole of the lead to be finally converted into carbonate.

The temperature of the stacks of pots in the Dutch process is about 113°. If it falls below 95°, a part of the lead escapes corrosion, and if it rises above 122°, the product is yellow. The formof acetic acid usually employed in this process is vinegar; but the variable nature of that liquid as to strength and purity is an objection to its use; and, accordingly, other forms of the acid have been substituted with advantage; as, for example, the purified acetic acid from wood in a diluted state. For further information in relation to the processes proposed or pursued for making white lead, the reader is referred to a paper by Prof. J. C. Booth, in the *Journal of the Franklin Institute* for Jan. 1842.

Still another method of manufacturing white lead has been proposed by Mr. Peter Spence, having been brought by him before the Nottingham meeting of the British Association. It has the recommendations of great simplicity, and of being applicable to ores or other mixtures of lead otherwise useless. It is based on the fact that oxide and carbonate of lead, unlike any other metallic oxide and carbonate, are dissolved by aqueous solution of caustic potassa or soda, but not of the carbonate of these alkalies; and all that is to be done is to macerate or boil in a caustic solution any impure oxide or carbonate of lead, or any mineral that can by calcination be converted into one of these compounds, after such conversion, and then to precipitate the carbonate of lead by passing carbonic acid through the solution. The white lead thus produced has been tried, and found to have all the qualities of the best article to be had in the market. (*Chem. News*, Sept. 28, 1866, p. 148.)

Properties. Carbonate of lead is a heavy, opaque substance, in powder or friable lumps, insoluble in water, of a fine white colour, inodorous, and nearly insipid. Its beauty as a pigment depends in a great measure on the purity of the lead from which it is manufactured. Sulphuretted hydrogen blackens it. It is wholly soluble, with effervescence, in dilute nitric acid; and the solution is precipitated white by sulphuric acid, and yellow by iodide of potassium. Ex-

posed to heat it becomes yellow, and with charcoal is reduced to the metallic state. It is sometimes adulterated with the sulphates of baryta, lime, and lead, particularly the first. M. Louyet has examined samples of French white lead, containing considerably more than half their weight of sulphate of baryta. These sulphates, if present, are left undissolved by nitric acid. Chalk or whiting is another adulteration. This may be detected by adding to the nitric solution of the white lead an excess of potassa, which will redissolve the protoxide of lead first thrown down, but leave a white powder of lime. Neutral carbonate of lead consists of one eq. of carbonic acid 22, and one of protoxide of lead 111·5 = 133·5. Commercial white lead is a compound of the carbonate and hydrate of lead. Mulder and Hochstetter make its formula to be $2(PbO,CO_2)+PbO,HO$. According to Stein, white lead, when submitted to simple calcination, loses 14·5 per cent of its weight; and a mode of determining its purity is thus afforded. (*Journ. de Pharm.*, Janv. 1859, p. 78.) But the fact seems to be, from the observations of Mr. Wm. Baker, that commercial white lead contains variable proportions of the hydrated oxide, from a mere trace to the amount of 1 eq. to 3 eqs. of the neutral carbonate. (*Chem. News*, Aug. 10, 1861, p. 74.)

Medical Properties and Uses. White lead is ranked in the Materia Medica as an astringent and sedative. It is employed externally only, being used, in the form of ointment, as an application to ulcers, and to inflamed and excoriated surfaces. It is recommended in scalds and burns by Prof. Gross; and Mr. Alfred Freer has found it very useful in erysipelas, eczema, carbuncle, &c. (*Pharm. Journ.*, Aug. 1859, p. 138.) The white lead is first brought to the consistence of cream by linseed oil, as in making common white paint, and then brushed over the inflamed surface. Its external use, however, is viewed by many practitioners as dangerous, on account of the risk of absorption; but the occurrence of bad effects is rare. A case, however, of colica pictonum from the white lead treatment of a severe scald is reported by Dr. G. A. Kunkler, of Madison, Ia. (See *N. A. Medico-chir. Rev.*, July, 1857, p. 605.)

Of the different preparations of lead, the carbonate is considered to be the most poisonous. Being extensively manufactured for the purposes of the arts, it is that preparation which, by slow absorption, most frequently produces the peculiar spasmodic colic, called *colica pictonum*. This disease is characterized by pain about the region of the navel, and by obstinate constipation attended with a frequent desire to evacuate the bowels, and is supposed to depend upon a spasmodic constriction of the intestinal tube, particularly of the colon. The principal indications in the treatment are, first to relax the spasm, and then to evacuate the bowels by the gentlest means. Opium and mild aperients, used alternately, are, accordingly, the best remedies, and among the latter castor oil and sulphate of magnesia are to be preferred. Indeed, the latter appears peculiarly adapted to the case; for, while it acts as an aperient, it operates to some extent as a counterpoison, by forming sulphate of lead with any soluble compound of the metal which it may meet with in the bowels. Calomel is often useful; and, if it happens to induce ptyalism, the complaint immediately yields. By some practitioners alum is deemed almost a specific in colica pictonum.

Pharm. Uses. In preparing Liquor Gutta-perchæ, *U. S.*

Off. Prep. Unguentum Plumbi Carbonatis. B.

PLUMBI NITRAS. *U.S.*

Nitrate of Lead.

Plumbum nitricum, *Lat.;* Nitrate de plomb, *Fr.;* Salpetersaures Bleioxyd, *Germ.;* Nitrato di piombo, *Ital.;* Nitrato de plomo, *Span.*

This salt was introduced into the Materia Medica of the U. S. Pharmacopœia, chiefly as one of the substances employed in the preparation of iodide of lead. Though formerly directed by the Edinburgh and Dublin Colleges, it was not retained in the first edition of the British Pharmacopœia. It holds a place, however, in the present, which gives the formula PbO,NO_5. The

following is the process given in the late Dublin Pharmacopœia for its preparation.

"Take of Litharge, in fine powder, *five ounces* [avoirdupois]; Pure Nitric Acid *two fluidounces;* Distilled Water *three pints* [Imp. meas.]; Dilute Nitric Acid *a sufficient quantity.* To the litharge, placed in a porcelain dish, add the acid with a pint and a half of the water, and, applying a sand heat, and occasionally stirring the mixture, evaporate the whole to dryness. Upon the residue boil the remainder of the water, clear the solution by filtration, and, having acidulated it by the addition of a few drops of the dilute nitric acid, evaporate until a pellicle begins to form. The heat being now withdrawn, crystals will form on the cooling of the solution, which should be dried on blotting-paper in a warm atmosphere, and preserved in a close bottle."

In this process the nitric acid unites directly with the protoxide of lead to form the nitrate. This is in beautiful, white, nearly opaque, tetrahedral or octohedral crystals, which are permanent in the air, of a sweet astringent taste, soluble in seven and a half parts of water, and in alcohol, and composed of one eq. of acid 54, and one of protoxide 111·5 = 165·5, without water of crystallization. "Its solution is precipitated black by hydrosulphate of ammonia, white by ferrocyanide of potassium, and yellow by iodide of potassium. When triturated with sulphuric acid, it forms a mixture, which colours morphia red, and, on being heated, evolves nitrous fumes." (*U. S.*)

Medical Properties, &c. The effects of this salt upon the system are the same as those of the other soluble salts of lead; but, though formerly employed, it is now quite out of use as an internal remedy. Externally it is occasionally applied to excoriated surfaces; and a solution made in the proportion of ten grains to an ounce of water, and coloured probably with alkanet, has been used on the continent of Europe, as a secret remedy, in sore nipples, chapped hands, cracked lips, &c. It has recently been found useful in the correction of fetid odours dependent on the presence of sulphuretted hydrogen or hydrosulphate of ammonia, which it decomposes. It is employed for this purpose in solution, which may be sprinkled in apartments, or applied to putrescent ulcers, or mixed with offensive discharges, the odour of which it is desirable to correct. It will not prevent the putrefaction of animal substances; and there is no reason to suppose that it is capable of rendering contagious or marsh miasms innoxious. *Ledoyen's disinfecting fluid* is a solution of nitrate of lead in the proportion of a drachm to an ounce. Should the salt be used internally, the dose would be from the fourth to the half of a grain.

Dr. Ogier Ward has found a solution extremely useful as an injection and lotion in cases of fetid discharges from the uterus and vagina, in gleety discharges from the urethra, in sloughing and indolent ulcers, and in chronic impetiginous affections of the skin. He prepares the solution extemporaneously by dissolving a scruple of carbonate of lead in sufficient diluted nitric acid for solution, and adding a pint of distilled water. The application is to be made twice or three times daily. (*Prov. Med. and Surg. Journ.*, Oct. 15, 1851.)

Off. Prep. Plumbi Iodidum. W.

PLUMBI OXIDUM. *U. S., Br.*

Oxide of Lead. Litharge.

Off. Syn. LITHARGYRUM. PbO. *Br.* 1864.

Plumbi Oxidum Semivitreum, *Lat.;* Semivitrified Oxide of lead; Oxide de plomb fondu Litharge, *Fr.;* Bleiglatte, *Germ.;* Litargirio, *Ital.;* Almartaga, *Span.*

When protoxide of lead is rendered semi-crystalline by incomplete fusion, it becomes the semivitrified oxide, or litharge. Almost all the litharge of commerce is obtained, as a secondary product, in the process for extracting silver from argentiferous galenas. After extracting the argentiferous lead from the ore, the alloy is calcined in the open air; whereby the lead becomes oxidized, and by fusion passes into the state of litharge, while the silver remains unchanged.

The following is an outline of the process. The lead containing the silver is placed upon an oval slightly excavated dish, about three feet long and twenty inches wide, called a *test*, made by beating pulverized bone-ash, formed into a paste with water, into a mould, the sides of which consist of an elliptical band of iron, and the bottom of strips of sheet-iron, placed at short distances apart. The test is of such a size as exactly to fit an opening in the floor of a reverberatory furnace, where it is placed and adjusted to the level of the floor. On one side of the test the fireplace is situated, and exactly opposite, the chimney; while at one extremity of it the pipe of a strong bellows is placed, and at the other a vertical hole is made, communicating with a gutter leading from the test. The furnace is now lighted, and shortly afterwards the bellows are put in motion. The lead fuses and combines with oxygen, and the resulting oxide, melting also, forms a stratum which swims on the surface, and which is driven, by the blast of the bellows, along the gutter and through the vertical hole into a recipient below, where, upon solidifying, it crystallizes in small scales, which form the litharge. In proportion as the lead is oxidized and blown off the test, fresh portions are added, so as to keep it always sufficiently full. The process is continued for eight or ten days, after which no more lead is added. The operation is now confined to the metal remaining on the test; and, the oxidation proceeding, a period at last arrives when the whole of the lead has run off as litharge, and the silver, known to be pure by its brilliant appearance in the fused state, alone remains. This is then removed, and the process repeated on a fresh portion of argentiferous lead.

Properties. Litharge is in the form of small, brilliant, vitrified scales, some presenting a red, and others a yellow colour. In mass it has a foliaceous structure. It is devoid of taste or smell. It slowly attracts carbonic acid from the air, and contains more of this acid the longer it has been exposed. It is on this account that it commonly effervesces slightly with the dilute acids. It has the property of decolorizing wines, when agitated with them. When heated with the fats and oils, in connection with water, it saponifies them. (See *Emplastrum Plumbi.*) Heated with charcoal it is reduced to the metallic state. In dilute nitric acid it should be almost entirely soluble; and the solution is affected in the same manner as that of the carbonate. (See *page* 688.) As it occurs in commerce, it usually contains iron, copper, and a little silver and silica. It may be purified from iron and copper by digestion in dilute sulphuric acid. The English litharge is most esteemed; that from Germany being generally contaminated with iron and copper. In choosing litharge, samples should be selected which are free from copper, and from fragments of vegetable matter. Copper is detected, if, upon adding ferrocyanide of potassium to a nitric solution of the litharge, a brown instead of a white precipitate is produced. Two varieties of litharge are distinguished in commerce, named from their colour, and dependent on differences in the process employed. Sometimes it has a pale-yellow colour and silvery appearance, and is then denominated *silver litharge* or *yellow litharge;* at other times it is of a red colour, and is known under the name of *gold litharge* or *red litharge.* The latter has been said to owe its colour to the presence of a portion of red lead; but M. Leblanc has shown that the two varieties of litharge differ in colour, structure, and density only, and not in chemical composition. In this respect litharge is essentially identical with the protoxide of lead. (See *Plumbum.*) The carbonic acid which it contains is variable; but its average amount is about 4 per cent. Peroxide of lead or red lead in litharge may be detected by heating it in a test tube with chloride of sodium and bisulphate of potassa, and introducing a slip of paper coloured blue by indigo. If either of these oxides be present, the paper will be bleached by the chlorine evolved. (*Journ. de Pharm.*, Mars, 1860, p. 237.)

Litharge is never used internally, but is employed in several pharmaceutical operations, and forms an ingredient in various external applications, used for abating inflammation, and for other purposes. By reaction with olive oil it forms the *Emplastrum Plumbi*, which is the basis of many of the *Plasters.* (See *Em-*

plastra.) In the arts it is employed in the glazing of pottery, in painting to render oils drying, and as an ingredient in flint glass.

PLUMBI OXIDUM RUBRUM.

Red Oxide of Lead.

Red lead, Minium; Deutoxide de plomb, Oxide rouge de plomb, Minium, *Fr.;* Mennig, *Germ.;* Minio, *Ital., Span.*

Preparation Red lead is prepared on the large scale in a furnace, with the floor slightly concave and the roof arched, presenting a general resemblance to a baker's oven. The lead is placed on the floor, and gradually raised to a red heat, whereby it melts and becomes covered with a pellicle of protoxide, which is removed by means of a long iron scraper; and the pellicles, as they successively form, are scraped off until the whole of the metal has been converted into them. The product is subjected to further calcination, with occasional stirring, for some time, in order to oxidize any particles of metallic lead. It is thus rendered yellow, and constitutes the *protoxide of lead*, or *massicot.* This is taken out of the furnace, thrown upon a level pavement, and cooled by being sprinkled with water. It is next reduced to fine powder by trituration and levigation, and dried; and in this state is introduced into large, shallow, square tin boxes, which are placed in another furnace, closed from the air, and heated nearly to redness; the heat being allowed gradually to fall during a period of from twenty-four to thirty hours. At the end of that time the protoxide of lead will have combined with an additional quantity of oxygen, and become the red oxide. This is taken out, and, having been passed through a fine wire sieve, is packed in barrels for the purposes of commerce.

The above is an outline of the French process for making red lead. In England and the United States, the calcination of the protoxide is not performed in tin boxes, but by returning it to the furnace in which it was first calcined. To save the first calcination, litharge is generally used for making the red lead of commerce, which consequently is liable to contain the impurities of that substance, consisting of iron, copper, and a little silver and silica. Copper is hurtful in red lead when used for making glass, to which it communicates colour. In order to have red lead of good quality, it should be made in large quantities at a time. It is also important that it be slowly cooled; for, as the absorption of oxygen by which it is formed takes place during a particular interval of temperature only, it is necessary that the heat, within that interval, should be maintained sufficiently long to allow all the protoxide to absorb its appropriate dose of oxygen. Red lead is also prepared by exposing litharge to a high temperature with nitrate or carbonate of potassa or soda.

Properties, &c. Red lead is in the form of a heavy, scaly powder, of a bright-red colour, with a slight shade of orange. Its sp. gr. is about 9. When exposed to heat it gives off oxygen, and is reduced to the state of protoxide. It is sometimes adulterated with red oxide of iron and red bole, substances which may be detected by treating the red lead with nitric acid, and testing the nitric solution with tincture of galls. This reagent will produce a black precipitate, in consequence of the iron being dissolved by the nitric acid If brick-dust be present, it will be left undissolved upon boiling the suspected specimen in water, with sugar and a small quantity of nitric acid. When free from impurities it is wholly reduced on charcoal by means of the blowpipe, giving a globule of metallic lead. It is completely soluble in highly fuming nitrous acid. (*Ed. Pharm.*) When treated with nitric acid it is resolved into protoxide which dissolves, and deutoxide which remains in the form of a dark-brown powder.

The red lead of commerce may be considered as a mixture of what may be called the true red oxide, and variable proportions of protoxide. That this is

its nature is rendered probable by the action of cold dilute acetic acid, not used in excess, which takes up a variable quantity of protoxide, leaving a portion unchanged in colour, which may be deemed the pure red oxide. This latter, when analyzed by nitric acid, has been proved, by the coincident results of Dalton, Dumas, and Phillips, to consist of three eqs. of lead, and four of oxygen, equal to $2PbO,PbO_2$ (Dumas), or PbO,Pb_2O_3 (Winckelblech). Mulder gives $Pb_4O_5 = 3PbO,PbO_2$, or $2PbO,Pb_2O_3$, as the usual composition of red lead.

Red lead enters into no officinal preparation. In the arts it is used chiefly as a paint, and in the manufacture of flint glass. B.

PODOPHYLLUM. *U. S.*

May apple. Podophyllum.

The rhizoma of Podophyllum peltatum. *U. S.*

Off. Syn. PODOPHYLLI RADIX. *Podophyllum Root.* The dried rhizome of Podophyllum peltatum. *Br.*

PODOPHYLLUM. *Sex. Syst.* Polyandria Monogynia. — *Nat. Ord.* Ranunculi, *Juss.;* Podophylleæ, *Lindley.*

Gen. Ch. Calyx three-leaved. *Corolla* nine-petaled. *Berry* one-celled, crowned with the stigma. *Willd.*

Podophyllum peltatum. Willd. *Sp. Plant.* ii. 1141; Barton, *Med. Bot.* ii. 9; Carson, *Illust. of Med. Bot.* i. 18, pl. 11. The may-apple, sometimes also called *mandrake*, is an indigenous herbaceous plant, and the only species of the genus. The root (rhizoma) is perennial, creeping, usually several feet in length, about one-quarter of an inch thick, brown externally, smooth, jointed, and furnished with radicles at the joints. The stem is about a foot high, erect, round, smooth, divided at top into two petioles, and supporting at the fork a solitary one-flowered peduncle. Each petiole bears a large, peltate, palmate leaf, with six or seven wedge-shaped lobes, irregularly incised at the extremity, yellowish-green on their upper surface, paler and slightly pubescent beneath. The flower is nodding. The calyx is composed of three oval, obtuse, concave, deciduous leaves. The corolla has from six to nine white, fragrant petals, which are obovate, obtuse, concave, with delicate transparent veins. The stamens are from thirteen to twenty, shorter than the petals, with oblong, yellow anthers, of twice the length of the filaments. The stigma is sessile, and rendered irregular on its surface by numerous folds or convolutions. The fruit is a large oval berry, crowned with the persistent stigma, and containing a sweetish fleshy pulp, in which about twelve ovate seeds are embedded. It is, when ripe, of a lemon-yellow colour, diversified by round brownish spots.

The plant is extensively diffused through the United States, growing luxuriantly in moist shady woods, and in low marshy grounds. It is propagated by its creeping root, and is often found in large patches. The flowers appear about the end of May and beginning of June; and the fruit ripens in the latter part of September. The leaves are said to be poisonous. The fruit has a subacid, sweetish, peculiar taste, agreeable to some palates, and may be eaten freely with impunity. From its colour and shape, it is sometimes called *wild lemon.* The root is the officinal portion, and is said to be most efficient when collected after the falling of the leaves. It shrinks considerably in drying.

Properties. The dried root is in pieces about two lines in thickness, with swelling, broad, flattened joints at short intervals. It is much wrinkled lengthwise, is yellowish or reddish-brown externally, and furnished with fibres of a similar, but somewhat paler colour. It was determined, by an experiment of Mr. Wm. Saunders, that these fibres contain as much active matter as the rhizoma itself. The fracture is short and irregular, and the internal colour whitish. The powder is light yellowish-gray, resembling that of jalap. The root in its aggregate state is nearly inodorous; but in powder has a sweetish not unpleasant smell. The taste is at first sweetish, afterwards bitter, nauseous, and

slightly acrid. Both the decoction and tincture are bitter; but alcohol is said to be the best solvent of the active matter. A bitter substance was extracted from the root by William Hodgson, jun., of Philadelphia, by boiling it with quicklime in water, straining the decoction, precipitating the lime with sulphate of zinc, evaporating the clear solution to the consistence of an extract, treating this with cold alcohol of 0·817, filtering and evaporating the alcoholic solution, and treating the residue with boiling distilled water, which deposited the substance referred to on cooling. (*Journ. of the Phil. Col. of Pharm.*, iii. 273.) Though the alcoholic solution of this substance is very bitter, it has upon trial been found not to be the purgative principle of the root. There can be little doubt, as suggested by Prof. F. F. Mayer, of New York, that the principle discovered by Mr. Hodgson is the alkaloid *berberina*. Indeed, the fact has been demonstrated by Mr. John M. Maisch, who separated this alkaloid from the mother-liquor remaining after the precipitation of the tincture by water. (*Am. Journ of Pharm.*, July, 1863, p. 303.) Prof. Mayer states, moreover, that the root contains, besides berberina, a colourless alkaloid. (*Ibid.*, March, 1863, p. 98.) Analyzed by Mr. John R. Lewis, podophyllum yielded albumen, gum, starch, extractive, lignin, gallic acid, fixed oil, traces of volatile oil, salts of potassa and lime, and two resinous principles, one soluble in alcohol and ether, and the other soluble in alcohol only. Both resins were found to possess the active properties of the root. Six grains operated as a drastic cathartic, with some emetic effect. (*Am. Journ. of Pharm.*, xix. 165.) To these ingredients saponin is to be added, on the authority of Prof. Mayer. (*Ibid.*, March, 1863, p. 98.) Dr. Manlius Smith recommends that the resin should be prepared by forming an alcoholic tincture of the root, evaporating the tincture till most of the alcohol is driven off, and throwing the residue into water, by which the resin is precipitated. The concentration should not be carried too far; as otherwise the resin separates in clots, which cannot be easily washed. According to Dr. Smith, the resin, when pure, is white, and purges actively in the dose of two or three grains. It is called *podophyllin*. (*Ibid.*, xxiv. 306.) For a more complete account of what is known of the resins of podophyllum, the reader is referred to the article on *Resina Podophylli* in *Part* II.

Medical Properties and Uses. Podophyllum is an active and certain cathartic, producing copious liquid discharges without much griping, or other unpleasant effect. In some cases it has given rise to nausea and even vomiting, but the same result is occasionally experienced from every active cathartic. Its operation resembles that of jalap; but is rather slower, and is thought by some to be more drastic. It is applicable to most inflammatory affections which require brisk purging; and is much employed in various parts of the country, especially combined with calomel, in bilious fevers and hepatic congestions. It is also frequently used, in connection with bitartrate of potassa, in dropsical, rheumatic, and scrofulous complaints. There do not appear to be sufficient grounds for ascribing to it special cholagogue powers. In minute doses, frequently repeated, podophyllum has been thought to diminish the frequency of the pulse, and to relieve cough; and for these effects has been given in hæmoptysis, catarrh, and other pulmonary affections.

The dose of the powdered root, as a purgative, is about twenty grains. An extract is prepared from it possessing all its virtues in a smaller bulk. (See *Extractum Podophylli*.) Podophyllin, or resin of podophyllum, which has become officinal, is considerably used. In its purest state, the dose as a laxative is from $\frac{1}{8}$ to $\frac{1}{4}$ of a grain; as a purgative, from $\frac{1}{4}$ of a grain to a grain.

POLYGALA RUBELLA. *U.S. Secondary.*

Bitter Polygala.

The root and herb of Polygala rubella. *U.S.*

POLYGALA. See SENEGA.

Polygala rubella. Willd. *Sp. Plant.* iii. 875; Bigelow, *Am. Med. Bot.* iii. 129. —*P. polygama.* Walter, *Flor. Car.* 179; Pursh, *Flor. Am. Sept.* 465. This species of Polygala is an indigenous, perennial plant, with a branching, somewhat fusiform root, which sends up annually numerous simple, smooth, and angular stems, from four to eight inches in height. The leaves are scattered, sessile, obovate or linear lanceolate, attenuated towards the base, obtuse, and mucronate. The flowers are purple, and in elongated terminal racemes. From the base of the stem proceed other racemes, which lie upon the ground, or are partially buried under it, and bear incomplete but fertile flowers, the calyx of which is without wings.

This plant is found in many parts of the United States, preferring a dry sandy or gravelly soil, and flowering in June and July. The whole plant is officinal. It has a strong and permanent bitter taste, which it yields to water and alcohol.

Medical Properties and Uses. In small doses bitter polygala is tonic, in larger, laxative and diaphoretic. The infusion of the dried plant has been usually employed to impart tone to the digestive organs. (*Bigelow.*) It appears to be closely analogous in medical virtues to *Polygala amara* of Europe, which is used for a similar purpose. W.

POTASSIUM.

Potassium.

Potassium, *Fr.;* Kalium, Kalimetall, *Germ.;* Potassio, *Ital.;* Potasio, *Span.*

Potassium is a peculiar metal, forming the radical of potassa, and of a number of other medicinal preparations. It was discovered in 1807 by Sir H. Davy, who obtained it by decomposing hydrate of potassa by galvanic electricity. It was afterwards procured in larger quantity by Gay-Lussac and Thenard, by bringing the fused alkali in contact with white-hot iron, which attracted the oxygen and set free the metal. The best process is that of Brunner, as modified by Wöhler, which consists in decomposing potassa in the state of carbonate, mixed with charcoal. The mixture of carbonate and charcoal is obtained by heating cream of tartar to redness in a covered crucible. For an account of some improvements in Brunner's process by MM. Mareska and Donny, see *Am. Journ. of Pharm.* (xxv. 70).

Potassium is solid, softer and more ductile than wax, easily cut with a knife, and of a silver-white colour. A newly cut surface is brilliant; but the metal quickly tarnishes by combining with the oxygen of the air, and assumes the appearance of lead. It possesses a remarkably strong affinity for oxygen, and is capable of taking that element from every other substance. On account of this property it must be kept in liquids, such as naphtha, which are devoid of oxygen. On the same account, when exposed with a fresh-cut surface to the air it becomes luminous through a slow combustion, like phosphorus in the dark. (*Chem. News*, Feb. 28, 1868, p. 108.) Its sp. gr. is 0·865, melting point 136°, equivalent number 39·2, and symbol K. When thrown upon water it swims, takes fire, and burns with a rose-coloured flame, combining with oxygen, and generating potassa which dissolves in the water. It forms numerous combinations, uniting with most of the non-metallic elements, and with several of the metals. It combines in two proportions with oxygen, forming a protoxide (*dry potassa*) of a gray, and a *teroxide* of a yellowish-brown colour It also unites with chlorine, and forms officinal compounds with iodine, bromine, sulphur, cyanogen, and ferrocyanogen, under the names of iodide, bromide, sul-

phuret, cyanide, and ferrocyanide of potassium. Its protoxide (dry potassa) is a strong salifiable base, existing in nature always in combination, and forming with acids a numerous and important class of salts. Of these, the acetate, bichromate, carbonate, bicarbonate, chlorate, citrate, hydrate (caustic potassa), nitrate, permanganate, sulphate, tartrate, and bitartrate are officinal, and will be described under their respective titles. B.

POTASSÆ BICHROMAS. *U. S., Br.*

Bichromate of Potassa.

BICHROMATE OF POTASH. $KO,2CrO_3$. *Br.*

Red chromate of potassa; Kali chromicum rubrum, *Lat.;* Bichrômate de potasse, *Fr.;* Zweifach Chromsaures Kali, *Germ.*

This salt is most conveniently prepared from the neutral or yellow *chromate of potassa*, by acidulating its solution with sulphuric acid, and setting it aside for a day or two. The acid withdraws one eq. of potassa from two of the neutral chromate, thus generating one eq. of the bichromate, which separates in orange-red crystals. The yellow chromate is obtained by igniting four parts of powdered chrome-iron ore (FeO,Cr_2O_3) with one part of nitre, and lixiviating the resulting mass with water. The solution, by evaporation, yields the yellow salt in crystals. In this process, the nitric acid of the nitre furnishes oxygen to convert the sesquioxide of chromium into chromic acid, which then unites with the potassa of the same salt. The iron, in the mean time, is sesquioxidized and rendered insoluble. Sometimes impure carbonate of potassa (pearlash) is substituted for part of the nitre in the calcination. Omitting the nitre entirely, Stromeyer, of Norway, in performing the ignition, has used lime along with the pearlash, with economical results. When lime is employed, chromate of lime is formed, which is extracted by lixiviation, and decomposed by a soluble salt of potassa. When desired, the bichromate may be obtained directly from the solution of chromate of potassa, derived from the treatment of the ore, by acidulating it with sulphuric acid, without first crystallizing it. For an account of the patent process of Prof. J. C. Booth, of this city, for obtaining bichromate of potassa, see *Pharm. Journ.* (xv. 34).

Bichromate of potassa is in the form of orange-red, anhydrous, prismatic crystals, soluble in ten parts of cold and much less boiling water, but insoluble in alcohol. Its solution has an acid reaction. Its taste is cooling and bitter. Exposed to a heat somewhat under redness, it fuses, without decomposition, into a red liquid, which congeals on cooling into a crystalline mass, and then falls into powder. At a red heat, it evolves oxygen, the neutral chromate and sesquioxide of chromium being left, of which the former body is dissolved, when the mixture is acted on by water. (*U. S.*) It consists of two eqs. of chromic acid and one of potassa. When one eq. of this salt is heated with four of sulphuric acid, *chromium-alum* is formed and oxygen evolved ($KO,2CrO_3$ and $4SO_3 = Cr_2O_3$, $3SO_3 + KO,SO_3$ and 3O).

Medical Properties, &c. Bichromate of potassa, in small doses, is alterative, in larger, emetic. Externally it acts as an irritant and caustic. It was first used internally, in 1850, by M. Robin, who gave it in secondary syphilis; and Prof. Heyfelder, of Erlangen, and M. Vicente afterwards employed it in the same disease with encouraging results. It acts like the mercurials on the syphilitic poison, and occasionally produces salivation. It was recommended, in 1827, by Dr. Cumin, in saturated solution, as a caustic application to tubercular elevations, excrescences, and warts, and in 1850 by M. Puche in syphilitic vegetations. It causes the morbid parts to shrivel and fall off. Dissolved in water, in the proportion of five grains gradually increased to a drachm to the fluidounce, it has been found useful in affections of the mucous membranes requiring astringents; and a solution has also been used with advantage for correcting the fetor of sloughing wounds. The dose as an alterative is one-fifth of a grain daily, in the form of pill made with extract of gentian, to be increased gradually to five

or six pills a day. As an emetic the dose is three-quarters of a grain. It may be used as a caustic in the form of powder. A solution of it has been used, as a local application, in various diseases of the skin "with complete success." (*Chem. News*, Jan. 20, 1865, p. 35.)

In overdoses it operates as a violent irritative and corrosive poison, producing severe vomiting, frequent dark hemorrhagic dejections, violent abdominal pains, &c. More than one fatal case is on record. When the stomach does not relieve itself by vomiting, magnesia, bicarbonate of soda, or a solution of soap should be immediately given as an antidote.

Bichromate of potassa is manufactured largely for the use of calico-printers. The workmen engaged in making it are liable to painful ulcerations of the hands; and, in consequence of the acrid vapours evolved, violent irritation of the nostrils is apt to be experienced, with severe pricking sensations and excessive sneezing, followed in time by destruction of the mucous membrane and even the septum itself. It is asserted that this result may be avoided by breathing through the mouth exclusively; the profuse secretion of saliva produced carrying off the poisonous particles. (*B. and F. Med.-chir. Rev.*, Oct. 1863, p. 533.) It was introduced into the Dublin Pharmacopœia of 1850, not as a therapeutic agent, but to be used in forming artificial valerianic acid by reacting with fusel oil (*Alcohol Amylicum*), as a step in the process for preparing valerianate of soda. (See *Sodæ Valerianas.*) For a full account of the manufacture of the chromium salts, used as dyes and pigments, see the *Pharmaceutical Journal* (xv. 32).

Pharm. Uses. In the preparation of Sodæ Valerianas, *U. S.* A solution of this salt, under the title of *volumetric solution of bichromate of potash*, has been introduced as a test into the British Pharmacopœia. B.

POTASSÆ BITARTRAS. *U. S.*

Bitartrate of Potassa.

Off. Syn. POTASSÆ TARTRAS ACIDA. *Acid Tartrate of Potash.* $KO,HO,C_8H_4O_{10}$. *Br.*

Supertartrate of potassa, Crystals of tartar, Cream of tartar; Cremor tartari, *Lat.;* Tartrate acide de potasse, Crême de tartre, *Fr.;* Doppelt weinsaures Kali, Weinsteinrahm, *Germ.;* Cremore di tartaro, *Ital.;* Cremor de tartaro, *Span.*

During the fermentation of wines, especially those that are tart, a peculiar matter is deposited in the casks, forming a crystalline crust, called *crude tartar* or *argol*. That deposited from red wines is of a reddish colour, and called *red tartar;* while that derived from white wines is of a dirty-white colour, and denominated *white tartar*. Both kinds consist of potassa, united with an excess of tartaric acid, forming bitartrate of potassa, rendered impure by tartrate of lime, more or less colouring matter, and other matters which are deposited during the clarification of the wine. The deposition of the tartar is thus explained. The bitartrate exists naturally in the juice of the grape, held in solution by saccharine matter. When the juice is submitted to fermentation in the process for converting it into wine, the sugar disappears, and is replaced by alcohol, which, not being competent to dissolve the salt, allows it to precipitate as a crystalline crust. It is from this substance that bitartrate of potassa is obtained by a process of purification.

The wines made in the United States of course deposit tartar; but as yet the product has not been collected for the purposes of commerce. According to Mr. E. S. Wayne, of Cincinnati, the American catawba wine deposits about three pounds of crude tartar from a hundred gallons. We are informed by him that American tartar contains at least 15 per cent. of tartrate of lime.

The process for purifying crude tartar is founded upon the greater solubility of bitartrate of potassa in hot than in cold water. The tartar, previously pulverized, is boiled with water in copper boilers. The solution, when saturated, is transferred to earthen pans, where it deposits on cooling a crystalline layer, nearly free from colour. This is redissolved in boiling water; and the solu-

tion, having been mixed with 4 or 5 per cent. of pipe-clay, is evaporated to a pellicle. The clay precipitates with the colouring matter; and the clear solution, as it cools, deposits white crystals in crusts, which, upon being exposed to the air on linen for several days, acquire an increased degree of whiteness. These constitute the *crystals of tartar* of pharmacy. The salt, however, as met with in the shops, is generally, for greater convenience, in the form of powder, to which the name *cream of tartar* properly belongs.

Wittstein proposes to free cream of tartar from lime by dilute muriatic acid, which dissolves the lime preferably, and, if not used in excess, will take up very little of the potassa salt. For remarks on this subject by Tenner, of Berne, see the *Am. Journ. of Pharm.* (Jan. 1862, p. 39).

Properties. Bitartrate of potassa occurs in commerce in white crystalline crusts, or masses of aggregated crystals, and is received in that state from France by our wholesale druggists, who procure its pulverization for the use of the apothecaries. In crystals it is hard and gritty between the teeth, and dissolves slowly in the mouth; in powder it has a white colour. It is a permanent salt, having a sour not ungrateful taste and acid reaction, soluble in 184 parts of cold, and 18 of boiling water, but insoluble in alcohol. When exposed to heat it is decomposed, exhales a peculiar odour, gives rise to several pyrogenous acids, and the usual products of the destructive distillation of vegetable matter; carbonate of potassa, mixed with charcoal, being left. Its solution is precipitated by solutions of baryta, strontia, and lime, which form insoluble tartrates, and by acetate of lead, forming tartrate of lead. With salifiable bases which form soluble tartrates, it gives rise to double salts, consisting of neutral tartrate of potassa, and the tartrate of the base added. Several of them are important medicines, and will be described under their respective titles. Cream of tartar, though sparingly soluble in water, becomes abundantly so by the addition of borax or boracic acid. (See *Sodæ Boras.*)

The cream of tartar of commerce is not pure bitartrate of potassa. It usually contains from 2 to 5 per cent. of tartrate of lime, an amount admissible in samples for medicinal use. But it sometimes contains from 6 to 13 per cent. of tartrate of lime, according to the analyses of Mr. J. M. Maisch. It is said to be purposely mixed with various substances, such as sand, clay, gypsum, flour, chalk, alum, and sulphate of potassa. Sand, clay, and gypsum may be detected by their insolubility in a hot solution of potassa; flour, by striking a blue colour with iodine; chalk, by its effervescing with dilute acids; alum, an unlikely sophistication, by its astringent taste; and any soluble sulphate, by causing a precipitate with chloride of barium, not entirely soluble in nitric acid. The action of the last-mentioned test is explained by the fact, that the tartrate of baryta is soluble in nitric acid, but not the sulphate. Another sophistication of cream of tartar is said to be with sugar of milk. The best security against fraud is to purchase the crystals, which are not so liable to adulteration as the powder. The U. S. Pharmacopœia gives the following test. The salt is dissolved freely by a hot solution of potassa, from which it is again deposited by the addition of an acid; and whatever remains undissolved is impurity. According to the Br. Pharmacopœia, 188 grains ignited till gas ceases to be evolved, leave an alkaline residue (carbonate of potassa) which requires for exact neutralization 1000 grain-measures of the *volumetric solution of oxalic acid.* This Pharmacopœia admits a slight impurity of lime, probably in the form of tartrate.

Composition. Cream of tartar consists of two eqs. of tartaric acid 132, one of potassa 47·2, and one of water 9 = 188·2. The water cannot be expelled without decomposing the salt, and is supposed to act the part of a base.

Medical Properties and Uses. Bitartrate of potassa is cathartic, diuretic, and refrigerant. In small doses it acts as a cooling aperient, in large ones as a hydragogue cathartic, producing copious watery stools; and, from this latter property, as well as its tendency to excite the action of the kidneys, it is much used in dropsical affections. It is frequently prescribed in combination with senna, sulphur, or jalap. (See *Confectio Sulphuris* and *Pulvis Jalapæ Com-*

positus.) Its solution in boiling water, sweetened with sugar and allowed to cool, forms an acid, not unpleasant, refrigerant drink, advantageously used in some febrile affections, and frequently employed as a domestic remedy. The beverage called *imperial* (*potus imperialis*) is a drink of this kind, made by dissolving half an ounce of the salt in three pints of boiling water, and adding to the solution four ounces of white sugar, and half an ounce of fresh lemon peel. *Cream of tartar whey* is prepared by adding about two drachms of the bitartrate to a pint of milk. It may be given, diluted with water, in dropsical complaints. The dose of cream of tartar is a drachm or two as an aperient; and from half an ounce to an ounce as a hydragogue cathartic, mixed with molasses, or suspended in water. As a diuretic in dropsical cases, it may be given in the dose of a drachm and a half or two drachms, several times a day.

In pharmacy, cream of tartar is employed to obtain the neutral tartrate of potassa (soluble tartar), tartrate of potassa and soda (Rochelle salt), tartrate of antimony and potassa (tartar emetic), and tartrate of iron and potassa (tartarized iron). Deflagrated with nitre, or incinerated alone, it is converted into a pure form of carbonate of potassa, called salt of tartar. In the laboratory it is used to procure potassa in a pure state, and for making black and white flux. *Black flux* is prepared by deflagrating cream of tartar with half its weight of nitre; and *white flux*, by deflagrating it with twice its weight of the same salt.

POTASSÆ CARBONAS IMPURA. *U. S.*

Impure Carbonate of Potassa.

The impure carbonate of potassa known in commerce by the name of *pearlash*. *U. S.*

Pearlash, Pearlashes, Impure potassa, Impure subcarbonate of potassa; Potasse du commerce, *Fr.;* Rohe Pottasche, *Germ.;* Potasch, *Dutch;* Potaske, *Dan.;* Potaska, *Swed.;* Potassa del commercio, *Ital.;* Cenizas claveladas, *Span.*

The alkali potassa, in the strict sense of the term, is the protoxide of the metal potassium. (See *Potassium.*) It exists in various states of purity. In its most impure state, it is the common potash of commerce. This, subjected to calcination, is rendered purer, and is then called *pearlash*, the form of the alkali designated by the officinal name at the head of this article.

Natural State and Preparation. Potash and pearlash of commerce are procured from the ashes of wood by lixiviation, and the subsequent evaporation of the solution obtained. The alkali exists in the wood, principally in the state of acetate; and, being of a fixed and incombustible nature, is left behind after the incineration. The wood is burnt on the ground, in a place sheltered from the wind. The ashes consist of a soluble and insoluble portion. The soluble part is made up of carbonate of potassa, together with sulphate, phosphate, and silicate of potassa, and the chlorides of potassium and sodium; the insoluble portion, of carbonate and subphosphate of lime, alumina, silica, oxidized iron and manganese, and a little carbonaceous matter that has escaped combustion. The ashes are lixiviated in barrels with the addition of a portion of lime, and the soluble substances above mentioned are taken up. The lixivium is then evaporated in large iron kettles, which for several days are kept constantly full. The evaporation is continued until the mass has become of a black colour, and of the consistence of brown sugar. It is now subjected to as powerful a heat as can be raised by the best wood fire for a number of hours, by which it is fused. During the fusion, the combustible impurities are for the most part burnt out, and a gaseous matter is emitted, which agitates the more fluid part. When the fusion is complete, the liquid becomes quiescent, and looks like melted iron. It is now transferred, by means of large iron ladles, to iron pots, where it con-

geals in cakes. These are broken up and packed in tight barrels, and constitute the *potash* of commerce. (*Dr. G. A. Rogers*, in *Silliman's Journal.*)

If it is intended to make *pearlash*, the process is varied. In this case the black matter of the consistence of brown sugar, called *black salts* by our manufacturers, instead of being fused, is transferred from the kettles to a large oven-shaped furnace, so constructed that the flame may play over the alkaline mass, which in the mean time is stirred by means of an iron rod. The ignition is in this way continued, until the combustible impurities are burnt out, and the mass, from being black, becomes of a dirty bluish-white colour. (*Rogers.*)

The ashes of plants amount generally to not more than a few parts in the hundred; and of these a portion only consists of potassa. The different parts of the same vegetable, and, for a stronger reason, different plants, furnish variable quantities of ashes. Ligneous plants yield less than herbaceous, the trunk less than the branches, and the branches less than the leaves. The bark yields more ashes than the wood; and the leaves of trees which drop their foliage in winter more than the leaves of evergreens. The following table gives the quantity of potassa contained in the ashes of one thousand parts of the undernamed plants:

Pine	0·45	Wheat straw	4·18	Dry oak leaves	24·0
Poplar	0·75	Flax	5·0	Common nettle	25·0
Birch	1·29	Rush	5·08	Black elder	25·5
Beech	1·45	Common thistle	5·37	Vetch	27·5
Oak	2·03	Vine branches	5·5	Poke	45·6
Oak bark	2·08	Barley straw	5·8	Wheat stalks	47·0
Box	2·26	Beech bark	6·0	Stems of potatoes	55·0
Willow	2·85	Fern	6·2	Wormwood	73.0
Linden	3 27	Indian corn stalks	17·5	Fumitory	79·0
Elm	3·9	Sun-flower stalks	19·4	Angelica	96·2
Maple	3·9				

Commercial History. Potash and pearlash are made in those countries in which forests abound. Accordingly, the alkali is extensively manufactured in Canada and the United States, and constitutes an important export of this country. It is prepared chiefly in the State of New York, which is supposed to furnish three-fourths of our exports of this alkali. It is also produced in considerable quantities in the northern countries of Europe, especially in Russia, and on the shores of the Baltic. It is of different qualities as it occurs in commerce, and is distinguished by the country or place of manufacture, as *American, Russian, Dantzic potash, &c.*

Potash has been extracted from felspar by Prof. Fuchs, by igniting it with lime, which renders the alkali slowly soluble in water. Dr. E. Meyer, of Berlin, has found that the extraction is facilitated by digesting the ignited mass with water under a pressure of seven or eight atmospheres. (*Pharm. Journ. and Trans.*, June, 1857, p. 607.) Other minerals have recently become the sources of potassa salts, especially a deposit of mixed chlorides of potassium and magnesium, overlying a bed of common salt, at Stassfurt, near Magdeburg, in Prussia. They are also extracted by M. Bulard from sea-water. (*Ibid.*, Feb. 1867, p. 451.)

Properties. Potash is in the form of fused masses, of a stony appearance and hardness, and caustic burning taste. Its colour is variegated; but reddish and dark-brown are the predominant hues. When exposed to the air it absorbs moisture and deliquesces; and, if sufficiently long exposed, finally becomes liquid. *Pearlash* is of a white colour, with usually a tinge of blue. As it occurs in commerce, it is in tight casks, containing about three hundred and fifty pounds, in which it forms one entire, hard, concrete mass. In the shops it is found in coarse powder, intermingled with lumps as dug out of the casks, presenting an opaque granular appearance, like table salt or Havana sugar. It is deliquescent, and has a burning alkaline taste. It is soluble in water, with the exception of impurities. The soluble matter in 100 grains of the salt of medium quality will neutralize about 58 grains of officinal sulphuric acid. It differs from potash principally in containing less combustible impurities and in being less caustic and deli-

quescent. The colouring matter of both these forms of alkali is derived from carbonaceous impurities, and small portions of iron and manganese.

Composition. The basis of both pot and pearlash is carbonate of potassa; but this is associated with certain salts, and with insoluble impurities. Several varieties of potash found in commerce were analyzed by Vauquelin, whose principal results are contained in the following table. The quantity examined of each kind was 1152 parts.

Kinds of Potash.	Caustic Hydrate of Potassa.	Sulphate of Potassa.	Chloride of Potassium.	Insoluble Residue.	Carbonic Acid and water.
American potash . .	857	154	20	2	119
Russian potash . . .	772	65	5	56	254
Pearlash	754	80	4	6	308
Dantzic potash . . .	603	152	14	79	304

These results, calculated for 100 parts, show that the American potash contains 74 per cent. of pure hydrated alkali, and the Russian 67 per cent. Pearlash, it is seen, is more rich in carbonic acid than potash; and this result of analysis corresponds with the qualities of the two substances as prepared in the United States; potash being known to be far more caustic than pearlash. Besides the impurities shown by the table, phosphate and silicate of potassa and chloride of sodium are present. According to Mr. Stevenson Macadam, the potashes of commerce contain iodine and a trace of bromine, which shows that the forest trees from which the alkali is obtained must contain a very minute proportion of these non-metallic elements. (*Chem. Gaz.*, Aug. 2, 1852, p. 284.)

As the potash of commerce is valuable in the arts in proportion to the quantity of real alkali which it contains, it is important to possess an easy method of ascertaining its quality in that respect. The process by which this is accomplished is called *alkalimetry*, and the instrument used an *alkalimeter*. The best mode of proceeding, which is applicable to the commercial forms of soda as well as those of potassa, is that proposed by Faraday, and described by Turner as follows. Take a cylindrical tube, sealed at one end, nine and a half inches long, and three-quarters of an inch in diameter, and pour into it one thousand grains of water, marking with a file the point at which the water stands. Divide the space occupied by the water into one hundred equal parts, graduating from above downwards; and, opposite to the numbers 23·44, 48·96, 54·63, and 65, severally, write the words soda, potassa, carbonate of soda, and carbonate of potassa. Then prepare a dilute sulphuric acid having the specific gravity 1·127, which may be formed by adding to the strong acid about four times its volume of distilled water. An acid of this strength, if added to the tube so as to reach to any one of the heights denoted by the above numbers, will be just sufficient to neutralize one hundred grains of the alkali written opposite to it. Suppose, for example, that the dilute acid be added until it stands opposite to the word carbonate of potassa, we shall then have the exact quantity necessary to neutralize one hundred grains of that carbonate; and if we add pure water, until the liquid reaches to 0, or the beginning of the scale, it is evident that the acid has been brought to the bulk of a hundred measures, each of which would be competent to neutralize one grain of the carbonate in question All that is now necessary, in order to ascertain the quality of any commercial sample of this carbonate, is to dissolve one hundred grains of it in warm water, filter the solution to remove insoluble impurities, and add by degrees the dilute acid from the tube until the solution is exactly neutralized, as shown by litmus paper. The number of divisions of acid, expended in attaining this point, may be read off from the tube; and for each division one grain of pure carbonate is indicated.

This method of testing the potash of commerce indicates its alkaline strength, assuming this to be dependent solely on potassa; but soda, a cheaper alkali,

may be present as an adulteration, and its proportion is important to be known. To solve this problem, M. O. Henry proposes that the saturating power of a given weight should be first determined in relation to sulphuric acid, and afterwards the proportion of carbonate of potassa in an equal weight, by first converting it into an acetate, and then precipitating the potassa by hyperchlorate (oxychlorate) of soda, the reacting salts being in alcoholic solution. The precipitated hyperchlorate of potassa indicates the proportion of carbonate of potassa. The amount of the latter determines how much of the sulphuric acid was expended in saturating the potassa; and the soda is indicated by the amount of this alkali equivalent to the remainder of the acid. (*Journ. de Pharm.*, vii. 214.) Another method of detecting soda in the potash of commerce, proposed by Pagenstecher, is to convert the suspected alkali into a sulphate, and to wash the sulphate formed with a saturated solution of sulphate of potassa. If the whole of the saline matter be sulphate of potassa, the washing will cause no loss of weight; but if part of it be sulphate of soda, this will be washed away, on account of its solubility in a saturated solution of sulphate of potassa. (*Ibid.*, Mars, 1848, 239.) Frémy has proposed the metantimoniate of potassa as a test for soda in potash. In applying this test, the potash is converted into a neutral chloride of potassium, and treated with a recent solution of the metantimoniate. If the alkali examined contain 2 or 3 per cent. of soda, a precipitate will be almost instantly formed. If a less proportion of soda be present, time and agitation will be necessary to effect the precipitation. Frémy states that, by this test, he can detect the half of 1 per cent. of soda in commercial potash. (*Philos. Mag.*, Oct. 1848, 325.) Good potash should not contain a proportion of chlorides, indicating more than 2 per cent. of chlorine by the test of nitrate of silver. If a larger proportion is shown, adulteration with common salt may be suspected. A standard solution of the silver salt may be made, a known measure of which shall be just sufficient to precipitate all the chlorine in a given weight of good potash, after having been supersaturated with nitric acid. If a further addition of the test causes a precipitate, the presence of too much chlorine is shown.

Pearlash, from its impurity, is never used as a medicine. Purified to a certain extent, it takes the name of carbonate of potassa.

POTASSÆ CHLORAS. *U. S., Br.*

Chlorate of Potassa.

Hyperoxymuriate of potassa; Chlorate de potasse, *Fr.;* Chlorsaures Kali, *Germ.*

In the U. S. Pharmacopœia, Chlorate of Potassa is placed in the Catalogue of Materia Medica; in the British, it is ranked among the Preparations, with the formula KO,ClO_5.

The salt may be conveniently obtained by the process of Graham, which consists in mixing carbonate of potassa with an equivalent quantity of hydrate of lime, before submitting it to the action of chlorine. The gas is absorbed with avidity, and the mass becomes hot, while water is given off. The lime converts the carbonate into caustic potassa, and the reaction then takes place between six eqs. of potassa and six of chlorine, with the result of forming five eqs of chloride of potassium, and one of chlorate of potassa. ($6KO$ and $6Cl = 5KCl$ and KO,ClO_5.) The products are, therefore, carbonate of lime, chloride of potassium, and chlorate of potassa. The chloride and chlorate are separated from the carbonate by solution in hot water, and the chlorate from the chloride by priority of crystallization. The Br. Pharmacopœia has adopted this process, with the following directions. "Take of Carbonate of Potash *twenty ounces* [avoirdupois]; Slaked Lime *fifty-three ounces* [avoird.]; Distilled Water *a sufficiency;* Black Oxide of Manganese *eighty ounces* [avoird.]; Hydrochloric Acid *twenty-four pints* [Imperial measure]. Mix the Lime with the Carbonate of Potash, and triturate them with a few ounces of the Water so as to make the mixture slightly moist. Place the Oxide of Manganese in a large retort or flask, and, having poured upon it the Hydrochloric Acid, diluted with six pints

[Imp. meas.] of water, apply a gentle sand heat, and conduct the Chlorine as it comes over, first through a bottle containing six [fluid]ounces of Water, and then into a large carboy containing the mixture of Carbonate of Potash and Slaked Lime. When the whole of the chlorine has come over, remove the contents of the carboy, and boil them for twenty minutes with seven pints [Imp. meas.] of the Water; filter and evaporate till a film forms on the surface, and set aside to cool and crystallize. The crystals thus obtained are to be purified by dissolving them in three times their weight of boiling Distilled Water, and again allowing the solution to crystallize."

In the first process, a large proportion of the potassa is lost by being converted into chloride of potassium. Prof. F. C. Calvert, of Manchester, almost entirely avoided this loss by his new process, in which he reacts upon one eq. of caustic potassa, mixed with five and a half eqs. of lime, with a stream of chlorine. The potassa is dissolved in sufficient water to form a solution, containing $10\frac{1}{4}$ per cent. of the alkali (sp. gr. 1·110), and mixed with the lime; and the mixture, after having been gradually heated to 122°, is subjected to a rapid current of chlorine to saturation, the reaction caused by which raises the temperature to about 194°. The product is then evaporated nearly to dryness, the residue dissolved in boiling water, and the solution filtered and set aside to crystallize. The strength of the solution of potassa, together with the increased temperature, determines the combination of part of the chlorine with calcium instead of potassium; and the oxygen from the lime converts the remaining chlorine into chloric acid. A higher or lower density of the potassa solution was found not to give equally favourable results. This process has been tried on a large scale, and is said to have been successful. While the original process gives but 43 parts of chlorate to 100 of anhydrous potassa, this process yields 260 parts. The same result in relation to the loss of potassa was gained in the British process by the use of a larger proportion of slaked lime.

The chlorate of potassa of commerce is prepared by the reaction of solutions of chloride of potassium and hypochlorite of lime, with the assistance of heat. The chlorate of potassa crystallizes during the refrigeration of the liquor, and chloride of calcium remains in solution (KCl and $3(CaO,ClO) = KO,ClO_5$ and $3CaCl$).

Properties. Chlorate of potassa is a white anhydrous salt, of a cooling and slightly acerb taste. It crystallizes in rhomboidal plates of a pearly lustre. It is soluble in 16 parts of water at 60°, and in two and a half parts of boiling water. When thrown on burning coals, it augments their combustion remarkably. This property is due to the presence of oxygen, which may be evolved from the salt, in the proportion of nearly 39 per cent., by heating it a little above its point of fusion. The residue is chloride of potassium.

Chlorate of potassa is characterized also by becoming first yellow, and then red by admixture with a little sulphuric acid, and by the action of that acid evolving chlorous acid gas (quadroxide of chlorine), known by its yellow colour, and explosive property when heated; by its bleaching power when mixed first with muriatic acid and then with water; and by its property of exploding violently when triturated with a small portion of sulphur or phosphorus, or even kermes mineral. Its usual impurity is chloride of potassium, which may be detected by a precipitate of chloride of silver being produced on the addition of nitrate of silver. This test does not precipitate the chlorine of the chloric acid. Chlorate of potassa consists of one eq. of chloric acid 75·5, and one of potassa 47·2 = 122·7.

This salt is an excellent test of manganese existing in organic matter. If a small portion of such matter, containing even a trace of manganese, be thrown on the surface of the *pure* melted salt in a test-glass, after the combustion has ceased, the cooled saline mass will be found to have a rose or pinkish tint, caused by the formation of permanganate of potassa. (*Neues Repert.*, vi. 247.) A similar discoloration of the salt, produced by the use of pure charcoal in the same manner, will evince the presence of manganese in the chlorate as an impurity.

Medical Properties. According to M. Socquet, the physiological action of chlorate of potassa is to depress the circulation, without the least effect on the

digestive organs. From experiments made by Dr. O'Shaughnessy and others, it gives a bright scarlet colour to the venous blood, and passes undecomposed into the urine. The first trials made with it as a medicine were founded upon the supposition that it would prove an oxidizing remedy; and hence it was employed in scurvy, and in syphilis and liver complaints as a substitute for mercury. In scurvy its use has been recently revived. It has also been employed in acute articular rheumatism, pseudomembranous angina and croup, ulcerative and gangrenous stomatitis of infants, and mercurial and maternal stomatitis. In these ulcerous affections there can be no doubt of its great efficacy in very many instances. Dr. Alexander Harkin, of Dublin, recommends it highly in scrofula and consumption. (*Dub. Quart. Journ.*, Nov. 1861.) At an earlier date, it had been tried advantageously in presumed cases of phthisis by Dr. Davenport, of Iowa. (*Am. Med. Monthly*, Sept. 1860.) Dr. Austin Flint, however, as the result of his own observations, denies that it has any specific influence on the disease. (*Am. Journ. of Med. Sci.*, Oct. 1861, p. 321.) It is much employed, and by some practitioners mainly relied on in scarlatina, diphtheria, and fetid breath. It has obtained some reputation also as a resolvent; and Mr. W. Craig, of Ayr, in Scotland, has reported three cases of large ovarian tumours, two of which disappeared, and the third was diminished, under the use of a dessertspoonful, thrice daily, of a saturated aqueous solution of the chlorate. (*Edin. Med. Journ.*, Nov. 1865, p. 427.) It has been thought in some instances to have prevented abortion.

Externally, chlorate of potassa in solution has been used in several diseases. Mr. Moore, of London, has found it very useful as an application to indolent and scrofulous ulcers and phagedæna, to ulcerations of the nose, mouth, and tongue, and for cleansing cancerous sores. It is even asserted to have caused the healing of cancroid ulcers. (*Journ. de Pharm.*, Mars, 1864, p. 269.) M. Ganjot found it successful in a case of severe phagedenic ulcers, which had long resisted other remedies; applying to each ulcer morning and evening by means of a compress a solution containing one part of the salt in 25 parts of water. (*Ann. de Thérap.*, 1866, p. 132.) Dr. S. F. Starley, of Fairfield, Texas, succeeded in curing, in a month, a case of long-standing catarrh of the bladder, by injecting into the bladder, daily at first, and afterwards every two or three days, from four to six ounces of a solution containing a drachm in eight ounces of water. (*Med. and Surg. Reporter*, Aug. 24, 1867, p. 169; from the *South. Journ. of Med. Sci.*) Dr. Bedford Brown, of N. C., has employed it with success, in the form of injection, in gonorrhœa in women, leucorrhœa, and ulceration of the os uteri. (*Am. Journ. of Med. Sci.*, July, 1857, p. 66.) The dose is from fifteen to thirty grains every three or four hours, given in sufficient gum water, sweetened water, or lemonade to dissolve it. When administered as a prophylactic in salivation, a smaller dose will answer. No nicety need be observed in the dose. Taken to the extent of five drachms in twenty-four hours, it was found to produce diuresis, abundant salivation, and a strong saltish taste. When used as a wash or injection, from a drachm to half an ounce of the salt may be dissolved in a pint of water. A solution in glycerin, in the proportion of one part of the salt to ten of the menstruum, has been especially recommended as a dressing for ill-conditioned wounds and ulcers. The remedy has also been applied in the form of very fine powder dusted on the surface.

B.

POTASSÆ NITRAS. *U. S., Br.*

Nitrate of Potassa.

KO,NO_5. Nitrate of potash of commerce, purified, if necessary, by crystallization from solution in distilled water. *Br.*

Nitre, Saltpetre; Nitrate de potasse, Azotate de potasse, Salpêtre, *Fr.*; Salpetersaures Kali, Salpeter, *Germ.*, *Dutch*, *Dan.*, *Swed.*; Nitro, *Ital.*, *Span.*, *Port.*

Nitre or saltpetre is both a natural and artificial product. It occurs in many

countries, existing in the soil on which it forms a saline efflorescence, in the fissures of calcareous rocks, and in caves. It has been found in different parts of Europe, in Egypt, and in Peru; but the country in which it is most abundantly produced is India, whence the principal part is furnished for the demands of commerce. In the United States it is found, for the most part, in caverns situated in limestone rock, called saltpetre caves, where it is associated with nitrate of lime. The earths contained in them are lixiviated, and yield, according to their richness, from one to ten pounds of crude nitre to the bushel. These caves are particularly numerous in Kentucky, and furnished a large proportion of the nitre consumed in the United States during the last war with England. According to Mr. E. S. Wayne, of Cincinnati, nitre earth exists near Nashville, Tenn., which yields 15 per cent. of nitre, and is said to be sufficiently abundant to supply the demand of the United States. In Bradford County, Penn., a solid, uncrystalline deposit of very pure nitre exists in a sandstone rock. (*Prof. W. H. Ellet.*) "A mountain" of the salt is said to have been discovered by Dr. Harrison among the Rocky Mountains, "six miles N. E. of Crystal Peak." (*Am. Journ. of Pharm.*, Jan. 1866, p. 87.) Nitre exists also in the vegetable kingdom, having been found in tobacco, borage, bugloss, parietaria, hemlock, and the sun-flower. The artificial sources of nitre are certain mixtures of animal and vegetable substances with wood-ashes and calcareous matter, called nitre-beds; and certain materials, impregnated with saltpetre, consisting principally of plaster rubbish, derived from the demolition of old buildings. The ashes of tobacco stems, consisting almost exclusively of carbonate of potassa and chloride of potassium in nearly equal parts, have been proposed by M. Commaille as an artificial source of nitre, by adding them to the ordinary nitre-beds. (*Journ. de Pharm.*, Fév. 1856, 106.)

Preparation from its Natural Sources. In India the saline earth, which contains about seven parts of nitre in a thousand, is lixiviated in large mud filters, lined with stiff clay, and furnished with false bottoms of bamboo, covered with grass mats, on which wood-ashes are laid. The filters being then filled with the saline earth, water is added, and the solution filters through the wood-ashes, with the effect of converting the nitrate of lime present, amounting to nearly 1 per cent., into nitrate of potassa. The solution obtained is evaporated in earthen pots, filtered, and set aside to crystallize. The impure nitre thus obtained contains from 45 to 70 per cent. of the pure salt. It is redissolved and crystallized, and thrown into commerce under the name of crude saltpetre.

Besides the nitre obtained in India by the filtration of the soil deposited during the overflow of the Ganges, it appears, from the report of Dr. J. W. Palmer, that much of the crude salt is obtained, in the northwestern Provinces of Hindostan, from the saline incrustations formed in and around the mud walls surrounding the dwellings of the natives. The scrapings from these sources are lixiviated, and the impure solution allowed to evaporate in shallow pans exposed to the sun. The impure nitre extracted from the earthy matters crystallizes out; while common salt, to the extent of from 1 to 9 per cent., remains in the mother-liquor, and is recovered by subsequent evaporation to dryness. (See *Am. Journ. of Pharm.*, Sept. 1868, p. 436.)

Artificial Preparation. The plan of forming saltpetre in artificial nitre-beds is principally practised in Germany; while the method of obtaining it from old plaster rubbish is followed in France. *Artificial nitre-beds* are formed of animal and vegetable remains, together with ashes and calcareous earth, which are mixed up with a portion of loose soil and placed under sheds, to shelter the mixture from the rain; while the sides are left open to permit the free access of air. The mixture is disposed in little ranges or heaps, which are frequently turned over with a spade, and sprinkled with urine, as a substance containing a large quantity of nitrogen. At the end of two or three years the nitrogen is converted into nitric acid, and this, by uniting with the potassa existing in the vegetable remains, forms nitre. When the contents of the bed contain about four ounces of the salt for every cubic foot of the materials, they are deemed fit to be

lixiviated. The lixiviation is performed with boiling water, which is repeatedly thrown upon fresh portions of the mass, until the solution obtained is sufficiently strong. The lixivium is of a brown colour, and contains chiefly the nitrate of potassa, but at the same time more or less of the nitrates of lime and magnesia, and of common salt. The earthy nitrates are then decomposed by a solution of wood-ashes, the potassa of which converts them into nitre, and precipitates the earths. The solution being further evaporated, the common salt rises to the surface as a scum, and is removed. The soluton is then allowed to cool, and the nitrate crystallizes in dirty-white crystals, called crude nitre. Nitrate of lime may be converted into nitre by adding it to a solution of sulphate of potassa. Sulphate of lime is precipitated, and nitrate of potassa remains in solution.

When obtained from old plaster rubbish, the material is reduced to powder and lixiviated, in order to exhaust it of everything soluble. The solution is found to contain the nitrates of potassa and lime, and common salt, and is treated with wood-ashes, which convert the nitrate of lime into nitrate of potassa, with precipitation of the earth as a carbonate. The liquor is separated from the precipitate and concentrated by heat; and the common salt, as it rises to the surface, is skimmed off. When the solution is so strong as to mark 45° of Baumé's areometer, it is allowed to cool and crystallize; and the crystals form the crude nitre of this process. The salt obtained in this way generally contains from 85 to 88 per cent. of pure nitre; the remainder being made up of chloride of sodium, and certain deliquescent salts. The details of this process, as formerly practised in Paris, are given by Thenard.

Theory of Nitrification. It is generally supposed that the continuous formation of nitre in nitre earths, and in artificial nitre-beds, depends upon the oxidation of the nitrogen of ammonia, thus generating nitric acid, the formation of which is facilitated by the presence of alkaline and earthy bases, with which the acid unites. The ammonia is derived, for the most part, from the organic remains in the nitre earths, and from the animal matter which is an essential ingredient in the artificial mixtures. According to Schoenbein, whose statement has been confirmed by Goppelsröder, the formation of the nitric acid is always preceded by that of nitrous acid. (*Journ. de Pharm.*, Avril, 1862, p. 334.)

Purification. Nitrate of potassa, as first obtained, either from natural or artificial sources, is called in commerce crude saltpetre, and requires to be purified before it can be used in medicine, or in most of the arts. The process, which is founded principally on the fact that nitre is more soluble than common salt in hot water, is conducted in the following manner in France. Thirty parts of saltpetre are boiled with six parts of water, and the portion which remains undissolved, or is deposited, consisting of common salt, is carefully removed. As the ebullition proceeds, a little water is added from time to time, to hold the nitre in solution. When common salt ceases to be separated, the solution is clarified with glue, and more water is added, at intervals, until the whole, including that previously added, amounts to ten parts. The clear solution is now transferred to large, shallow copper coolers, where it is agitated with wooden instruments to hasten the cooling, and to cause the nitre to crystallize in small grains. The purification is completed by washing the salt with water, or a saturated solution of nitre, in a kind of wooden hopper, with holes in the bottom stopped with pegs. The liquid employed is allowed to remain in contact with the nitre for several hours, after which it is permitted to drain off by taking out the pegs. The salt is now dried, and takes the name of purified nitre.

In Sweden, the process of purification is conducted in a different manner. The solution of the crude nitre is boiled until a saline crust (common salt) forms on its surface, and until it is so far concentrated that a small portion of it crystallizes upon cooling. The crust being removed, the solution is filtered, and diluted with 1-48th of water, with a view to retain in solution the common salt, which, being somewhat less soluble in cold than in boiling water, would otherwise be in part precipitated on refrigeration. The solution is now allowed to cool, and, at

the moment crystals begin to form, is stirred constantly to cause the salt to crystallize in small grains. The granular salt is then washed after the French method, as above described, dried, and, being fused, is cast in sheet-iron moulds so as to form masses, each weighing from ten to twenty pounds. The preparation of nitre in this manner by fusion is, according to Berzelius, attended with several advantages; such as its occupying less space, its losing nothing by waste in transportation, and its presenting, in this state, an obvious index of its quality. This index is the character of its fracture. When the salt is perfectly pure, the fracture is radiated, the radii being generally large. The presence of 1-80th of common salt renders the radii smaller; and of 1-40th, or a larger quantity, produces a zone in the substance of the mass devoid of the radiated structure, or causes this structure to disappear entirely. On the other hand, the melting of the salt has the disadvantage of converting it in part into nitrite if the heat be too high, and of rendering it difficult to pulverize.

The British Pharmacopœia of 1864 gave a process for purifying commercial nitre; but, as this is done on a large scale by the manufacturers, the process has been very properly omitted in the present edition. It may be seen in the preceding edition of this work.

Commercial History. Nitre is received in this country from Calcutta, packed in grass-cloth bags, containing from one hundred and fifty to one hundred and seventy-five pounds. The greater portion of it arrives at Boston. Its quality varies considerably. That which comes in dirty-yellow crystals is called *crude saltpetre;* while the finer lots, in small, comparatively clear crystals, approaching to white, are called *East India refined.* Very little crude saltpetre is at present obtained from native sources in the United States. The *refined saltpetre* is almost exclusively prepared by our own chemists.

As connected with the subject of saltpetre, it may be proper in this place to notice what is incorrectly called *South American saltpetre,* considerable quantities of which have been received within a few years from Peru and Chili. It is nitrate of soda, and comes in bags containing about 270 pounds of the salt in the crude state. This nitrate is used by our manufacturing chemists, and is better suited than nitre for preparing nitric and sulphuric acids, on account of its greater proportional quantity of acid. It is, however, not applicable to the purpose of making gunpowder, from its tendency to absorb moisture.

Nitrate of soda may be decomposed, so as to yield nitre, by means of *caustic* American potash (red potash of commerce), by Mr. Rotch's patented process. This process gives a nitre equal in purity to the East India refined. For the details, see the *Pharm. Journ. and Trans.* (xi. 36). The same salt will furnish nitre by double decomposition with pearlash. (*Ibid.*, xi. 236.) Mr. Hill decomposes nitrate of soda by means of chloride of potassium, forming, by double decomposition, nitrate of potassa and chloride of sodium. The latter is got rid of, in the usual manner, by evaporating the solution of the mixed salts.

Properties. Nitre is a white salt, possessing a sharp, cooling, and slightly bitterish taste, and generally crystallized in long, striated, semi-transparent, six-sided prisms, with dihedral summits. It dissolves in four or five times its weight of cold, and in about two-fifths of its weight of boiling water. It is sparingly soluble in rectified spirit, but insoluble in absolute alcohol. It undergoes no alteration in the air, unless this is very moist. It yields a yellow precipitate with bichloride of platinum, showing that potassa forms its base. It is devoid of water of crystallization; but is apt to contain a portion of liquid, mechanically lodged within the substance of the crystals. This is particularly the case with the *large* crystals, and, according to Berzelius, is a source of impurity; as the liquid in question is a portion of the mother-water in which they were formed. It is on this account that Berzelius recommends that the solution of the purified salt should be stirred during crystallization, so as to cause it to shoot into *small* crystals. When exposed to heat, nitre fuses without losing weight at about 662°. The fused mass, when cast in moulds, or formed into little circular cakes, constitutes that form of nitre kept in the shops under the name of *crystal min-*

eral or *sal prunelle.** If the heat is increased, the salt is decomposed, evolves pure oxygen, and is reduced to the state of nitrite, which, when rubbed to powder, emits orange-coloured fumes of hyponitric acid, and nitric oxide on the addition of sulphuric acid. Upon a further continuance of the heat, the nitrous acid itself is decomposed, and a large additional quantity of oxygen is evolved, contaminated, however, with more or less nitrogen. On account of the large proportion of oxygen which it contains, nitre increases the combustion of many substances in a remarkable degree. When thrown on burning coals, it deflagrates with bright scintillations. In the reaction of nitre with charcoal, carbonic acid is produced, and never carbonic oxide; and the nitric acid is variously decomposed into nitrous acid, nitric oxide, or nitrogen, according to the proportion of the charcoal and to the heat employed. (*A. Vogel, jun.*) Nitre may be readily recognised by its effect in increasing the combustion of live coals, when thrown upon them; and by evolving white or reddish vapours on the addition of sulphuric acid. Its most usual impurity is common salt, which is seldom entirely absent, and which injures it for the manufacture of gunpowder. The presence of this salt, or of chloride of potassium, will cause a precipitate with nitrate of silver. If a sulphate be present, a precipitate will be formed with chloride of barium. Of the pure salt, 100 grains, treated with 60 grains of sulphuric acid, and ignited until it ceases to lose weight, yield 86 grains of sulphate of potassa. If the residue weighs less, part of it is probably sulphate of soda, and the nitre tested may be assumed to have contained nitrate of soda. The refined or purified saltpetre of commerce is sufficiently pure for medicinal use. Nitrate of potassa is composed of one eq. of nitric acid 54, and one of potassa $47{\cdot}2 = 101{\cdot}2$.†

Medical Properties. Nitre is considered refrigerant, diuretic, and diaphoretic, and is much used in inflammatory diseases. It is known to be a powerful antiseptic. It generally promotes the secretion of urine and sweat, lessens the heat of the body and the frequency of the pulse, and has a tendency to keep the bowels in a soluble condition. When taken in health, in quantities increasing gradually from one to five drachms daily, for the space of from eight to twelve days, it was found by F. Löffler to produce general weakness, lowness of spirits, constant disposition to sleep, and slow and weak pulse. Towards the end of the experiment, the pulse several times fell to twenty beats in the minute. During the use of the medicine, the appetite and digestion continued good, and the bowels were regular; though, occasionally, some pain was experienced in the abdomen, followed by purging. The blood, drawn at the end of the period, resembled cherry juice in colour, exhibited paler blood corpuscles than in health, coagulated very quickly, forming a clot of diminished firmness, was more watery than natural, and contained a smaller proportion of fat. (*Am. Journ. of Med. Sci.*, xviii. 204; from *Schmidt's Jahrb.*)

Nitre is very frequently prescribed with tartar emetic and calomel, forming a combination usually called the *nitrous powder*, which promotes most of the secretions, particularly those of the liver and skin, and which in many cases is advantageously employed in lessening and modifying febrile excitement. The formula usually preferred is eight or ten grains of nitre, the eighth of a grain of tartar emetic, and from the fourth to the half of a grain of calomel, exhibited every two or three hours. Nitre is frequently given in active hemorrhages, particularly hæmoptysis, and is a useful ingredient of gargles in certain stages of inflammatory sorethroat. Dr Frisi, an Italian physician, found it very efficacious, in a case of obstinate spasmodic asthma, in affording speedy relief, and cutting short the attack as often as it was repeated. In the same disease, nitrous fumi-

* *Sal prunelle*, as directed to be made in the French Codex of 1837, is a mixture of nitrate and sulphate of potassa. It is prepared by fusing nitre in a Hessian crucible, adding 1-128th part of sulphur, and pouring out the product on a smooth marble slab, where it is allowed to congeal. The sulphur immediately takes fire, and, by combining with oxygen from a part of the nitric acid of the nitre, becomes sulphuric acid, which then unites with a small portion of potassa, to form sulphate of potassa.

† A method of estimating the nature and amount of the various impurities in commercial saltpetre has been published by M. Persoz, and may be seen in the *Am. Journ. of Pharm.*, Nov. 1861, p. 543.

gation has been found useful, performed by inhaling the fumes from a piece of burning touch-paper about the size of a playing card, prepared by dipping blotting-paper in a saturated solution of nitre, and afterwards drying it. M. Vohl has examined the vapour resulting from the burning of paper thus impregnated, and found it to consist of carbonic acid and oxide, cyanogen, ammonia, nitrogen, aqueous vapour, and carbonate and nitrite of potassa; and ascribes the beneficial results of its inhalation to the ammonia and nitrite of potassa. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 155, A. D. 1866.) In the form of sal prunelle, it has been strongly recommended by M. Debout in polydipsia, given in the dose of a drachm daily. Dr. Henry Tiedemann, of this city, praises nitre as a remedy in dysentery. The usual dose is from ten to fifteen grains, dissolved in water or some mucilaginous liquid, and repeated every two or three hours. If given too freely, or for too long a period, it is apt to excite pain in the stomach. In an overdose (half an ounce to an ounce or more), taken in concentrated solution, it causes heat and pain in the stomach, vomiting and purging of blood, great prostration, convulsions, and sometimes death. On dissection, the stomach and intestines are found inflamed. A fatal case of poisoning by nitre, in which, although three ounces and a half were taken at one dose, no painful symptoms were manifested, is related by Dr. John Snowden, in the *New Jersey Med. Reporter* (viii. 117). The treatment consists in the speedy removal of the poison from the stomach, and in the administration of mucilaginous drinks, laudanum to allay pain and irritation, and cordials to sustain the system. No antidote is known.

Notwithstanding the toxical properties of nitre when taken largely in concentrated solution, it may be given, in divided doses, to the extent of one or two ounces in twenty-four hours, if copiously diluted with water. Administered in this way, the salt acts as a sedative on the circulation, decreasing the force and frequency of the pulse. It is chiefly in *acute* rheumatism that large doses have been employed; and both M. Gendrin and M. Martin-Solon bear testimony to its remarkable efficacy in that disease, when thus given. Dr. Henry Bennett, of London, also speaks highly of its efficacy in the same disease; and his favourable report of it is confirmed by some well-conducted clinical experiments by Dr. R. Rowland, of the same city. The remedy was given by the latter in a quantity never exceeding half an ounce in twenty-four hours, dissolved in a pint of water. Thus administered, it produced no inconvenience. Large doses of this salt have also been employed with success in general dropsy, following remittent fever. It is best given, dissolved in sweetened barley-water, in the proportion of half an ounce to a pint and a half or two pints of the liquid.

Dr. Mangenot recommends, for the removal of cutaneous nævi, the topical use of nitre, applied by friction with the moistened finger, dipped into the powdered salt. (*Half-yearly Abstract*, Jan. to July, 1857, p. 120.)

In pharmacy nitre is employed to form crocus of antimony, to procure nitric acid, and sometimes in the preparation of sweet spirit of nitre. It enters into the composition of moxa. In the laboratory it is used to make black and white flux, and to yield oxygen at a red heat. In the arts it is employed in the production of aqua fortis (common nitric acid), the manufacture of sulphuric acid, and the fabrication of gunpowder. The Br. Pharmacopœia uses it in the purification of bismuth.

POTASSÆ PERMANGANAS. *U. S.*, *Br.*

Permanganate of Potassa. Hypermanganate of Potassa.

PERMANGANATE OF POTASH. KO,Mn_2O_7. *Br.*

This is a new officinal of the U. S. and Br. Pharmacopœias. In the former it is placed in the Materia Medica list, as an article to be procured from the manufacturer. In the latter a process is given for its preparation. The following is the British formula.

"Take of Caustic Potash *five ounces* [avoirdupois]; Black Oxide of Manganese, in fine powder, *four ounces* [avoird.]; Chlorate of Potash *three ounces and a half* [avoird.]; Diluted Sulphuric Acid *a sufficiency;* Distilled Water *two pints and a half* [Imperial measure]. Reduce the Chlorate of Potash to fine powder, and mix it with the Oxide of Manganese; put the mixture into a porcelain basin, and add to it the Caustic Potash, previously dissolved in four [fluid]ounces of the Water. Evaporate to dryness on a sand bath, stirring diligently to prevent spurting. Pulverise the mass, put it into a covered Hessian or Cornish crucible, and expose it to a dull red heat for an hour, or till it has assumed the condition of a semifused mass. Let it cool, pulverise it, and boil with a pint and a half [Imp. meas.] of the Water. Let the insoluble matter subside, decant the fluid, boil again with half a pint [Imp. meas.] of the Water, again decant, neutralise the united liquors accurately with the Diluted Sulphuric Acid, and evaporate till a pellicle forms. Set aside to cool and crystallise. Drain the crystalline mass, boil it in six [fluid]ounces of the Water and strain through a funnel, the throat of which is lightly obstructed by a little asbestos. Let the fluid cool and crystallise, drain the crystals, and dry them by placing them under a bell jar over a vessel containing sulphuric acid." *Br.*

By this process chlorate of potassa yields oxygen to binoxide of manganese, converting it into permanganic acid, which unites with the potassa to form the permanganate, chloride of potassium being formed at the same time; but as the whole of the materials, however accurately the proportions may be calculated, do not react upon each other to the desired result, portions of the binoxide and of the potassa remain. Hence, when exhausted by water, the solution contains with the permanganate and chloride an uncertain proportion of potassa, which requires to be neutralized by sulphuric acid. Unfortunately, it is extremely difficult to get rid of the sulphate of potassa and chloride of potassium, in the crystallization, which, therefore, are apt to contaminate the permanganate. At best the product is small and uncertain in amount; and the process, therefore, which is a modification of Gregory's, is not likely to be generally adopted. Several other processes have been employed, among which a very simple one is that by Græger. This chemist prepared the salt by first obtaining the pure oxide of manganese by calcining the carbonate, then calcining together a mixture of 130 parts of the oxide, 100 parts of chlorate of potassa, and 184 parts of hydrate of potassa, as free from carbonic acid as possible. The carbonate is easily procured, as an incidental product in the preparation of chlorine, by precipitating the muriatic liquor by carbonate of soda. To complete the process, the salt is obtained separate by solution, evaporation, and crystallization. (*Ann. de Thérap.*, 1867, p. 230.) According to Dr. E. R. Squibb, the best of the methods proposed is the following by M. Béchamp, of Montpellier.

Ten parts of binoxide of manganese, in fine powder, are intimately mixed with 12 parts of potassa dissolved in a little water, and the mixture is thoroughly dried. This is introduced into an earthenware retort, furnished with a tube passing through the tubulure nearly to the bottom. The retort is placed in a furnace, and to the beak a bent tube is adapted, the end of which dips into mercury. Heat is then applied, and a current of oxygen, or of atmospheric air freed from carbonic acid, is made to enter into the retort through the tube in the tubulure, as long as absorption continues. The mass is then exhausted with water, and carbonic acid is passed through the solution until it acquires a red or purple colour. After standing so as to allow of the subsidence of the undissolved matter, the liquid is decanted, evaporated without ebullition, and allowed to crystallize. The crystals are purified by a second crystallization. In this process the requisite oxygen for peroxidizing the manganese is supplied from a distinct source, and the disadvantage from the presence of other salts avoided. The action of the carbonic acid is to convert into carbonate the excess of potassa, which, so long as allowed to remain, prevents the conversion into permanganic acid of the manganic acid formed in the earlier stage of the process.

For satisfactory results it is desirable that, while a heat sufficient in degree

and sufficiently prolonged is employed, it should not be so great as to decompose the new acid formed, and that a long continuance of heat in the extraction of the salt from the mass by water, and in the subsequent evaporation of the solutions, should be avoided, as it also favours decomposition. Hence the propriety of using a steam-heat, and of obtaining the salt with as little admixture as possible of other salts, which require repeated solution and evaporation to separate them. The latter is one of the main advantages of Béchamp's process. Dr. Squibb, after much attention to the subject, and many experiments, proposes a method in which these difficulties are avoided, and which has the recommendation of simplicity and economy. We have space only for an outline of his process, and refer for details to his article in the *Am. Journ. of Pharm.* for Sept. 1864.

Fused hydrate of potassa is heated with a little water in a cast-iron vessel, the bottom of which is made nearly red-hot; binoxide of manganese is added, and the mixture stirred till dry. It is then powdered, and subjected repeatedly to the action of water at an elevated temperature, being stirred to dryness after each addition. This operation is repeated four times. After the last addition of water the vessel is removed from the fire, and, time being allowed for subsidence, the clear liquor is decanted. The operation is twice repeated with the residue, after which the undissolved matters are thrown away. The liquors thus obtained are mixed and evaporated, care being taken to avoid too high a heat; and the residue is set aside to crystallize. The crystals are then drained in a funnel, the neck of which is obstructed with pieces of glass; as it is of the utmost importance that the salt shall not come in contact with organic matter. A further product of crystals is obtained by a repetition of the process; the mother-water being used, instead of pure water, for the solution of the potassa. The crystals thus obtained are washed with distilled water, then dissolved in boiling distilled water, and recrystallized. The yield of pure crystals may be from 16 to 25 per cent. of the oxide employed, according to the care used in conducting the process.

Subsequent experience has convinced Dr. Squibb that the recrystallization is unnecessary and wasteful; the product of crystals first obtained being sufficiently pure for all ordinary purposes, and the little free potassa contained therein being useful, if not essential, in preserving the salt from decomposition in solution. (*Am. Journ. of Pharm.*, Jan. 1865, p. 22.)

The rationale of this process, which appears to us to be an excellent one, is probably as follows. When the binoxide of manganese and potassa are heated together, a portion of the binoxide, under the influence of the potassa and heat, gives up to another portion so much oxygen as to convert it into manganic acid (MnO_3), which combines with potassa to form the manganate. But this salt, when dissolved in water, rapidly changes to the permanganate, probably by the surrender of one eq. of oxygen by one eq. of the manganic acid, by which it is converted into deutoxide (MnO_2), to two other eqs. of manganic acid, converting them into one eq. of the permanganic (Mn_2O_7). The manganic acid thus becomes a carrier of oxygen from the deutoxide, and, though a small portion may be formed at once, yet, by its successive formation and decomposition, it at length gives a considerable proportional product.

Properties. Permanganate of potassa (KO,Mn_2O_7) is in the form of slender prismatic crystals, of a dark-purple colour, inodorous, and of a sweetish, astringent taste. It is said to be soluble in 16 parts of water at 60° (*Brande and Taylor*); but, according to M. Reveil, it is dissolved by 5 times its weight at common temperatures. (*Arch. Gén.*, Janv. 1864, p. 24.) Its solution, even with a minute proportion of the salt, has a beautiful lilac colour. If the solution be evaporated to dryness, the salt has the form of an intensely black powder. If suddenly heated, the crystals detonate; evolving oxygen, and leaving a black residue, which yields potassa to water, recognised by its alkaline reaction, and by giving, when acidulated with muriatic acid, a yellow precipitate with bichloride of platinum. (*Br.*) Moderately heated, they are partially volatilized, giving out violet vapours, of a disagreeable metallic odour. (*Am. Journ. of Pharm.*, Sept. 1862, p. 409.) This salt, in consequence of the facility with which it parts with

oxygen, is one of the most powerful oxidizing agents known. It causes the combustion of certain inflammable bodies, imparts oxygen to almost all organic substances, and in chemistry is employed to bring various compounds to a higher degree of oxidation. It has been conjectured that a part of the oxygen contained in it is in the state of ozone, and to this has been ascribed its extraordinary oxidizing power. But the readiness with which it yields oxygen in the nascent state, is sufficient to account for the phenomena. It may be kept indefinitely if pure, and carefully secured from contact with organic substances, or other decomposing agents; but, in fact, in consequence of the almost universal presence of organic matter in the air, it is generally partially decomposed, and, when dissolved, leaves a slight residue of hydrated binoxide of manganese. In reference to the metals, mercury is quickly oxidized at the expense of the salt; a mixture of protoxide of mercury and oxide of manganese being deposited as a brown powder, and caustic potassa remaining in solution. Zinc remains unchanged indefinitely in a solution of the permanganate, silver is little affected, and copper not at all even at 212° F. (Giles, *Journ. de Pharm. et de Chim.*, Mai, 1868, p. 397.)

The U. S. Pharmacopœia gives as a test, that its solution is instantly decolorized by the solution of arsenite of potassa, with the production of a brown precipitate. The British requires that 5 grains, dissolved in water, should be completely decolorized by not less than 44 grains of granulated sulphate of iron, acidulated with two fluidrachms of officinal dilute sulphuric acid.

Medical Properties and Uses. Permanganate of potassa was first brought to the notice of the profession, in 1857, by Mr. Condy as a powerful disinfectant; and, since that time, has been very extensively and satisfactorily employed, so that it now ranks among the most efficient agents, and by some is considered superior to all others. Not only has it an extraordinary power of destroying fetid odours from organic sources; but it is thought even to destroy poisonous emanations, and thus to prove useful in preventing the spread of infectious diseases. It is used also very successfully in the treatment of fetid and gangrenous ulcers, abscesses, and wounds of all kinds, of fetid discharges from the mucous membrane in ozæna, otorrhœa, and leucorrhœa, and of diphtheritic affections; and it has proved serviceable even in cancerous ulcers, as of the face, mouth, and uterus. In this country, it has been employed extensively and with extraordinary success in hospital gangrene. As a local stimulant it has also been used in chronic and indolent ulcers. Dr. T. L. Leavitt, of this city, has employed it with the most satisfactory results in carbuncle. (*Am. Journ. of Med. Sci.*, Jan. 1867, p. 131.) In all these cases, it is applied to the diseased surface in solution of various strengths, according to the effect desired. In concentrated solution, it is capable of acting as a caustic, and therefore requires caution. With the view to its caustic action, it may be sprinkled on the diseased surface by means of a pepper-box, or applied in strong solution. As a disinfectant lotion it may be of various strengths, from one to ten grains to the fluidounce of water. M. Demarquay, who was among the first to employ it, uses for injection in cancer of the womb, and for application to gangrenous and fetid abscesses, a solution varying in strength from 5 to 20 parts of the salt to 100 of water, trying the weaker solution first. (*Ann. de Thérap.*, A. D. 1864, p. 251.) M. O. Reveil recommends as a standard solution 10 parts dissolved in 90 parts of water. This may be used of its full strength in dressing cancerous, phagedenic, and atonic ulcers, and diphtheritic patches at the beginning. In consequence of its action on organic bodies, it should be applied by a pencil of amianthus, or sprinkled over a dressing of the same material upon the surface. For dressing simple wounds, or as an injection in ozæna, leucorrhœa, &c., half a fluidounce may be used to a pint of water; in gangrenous and diphtheritic wounds and scrofulous ulcers, and as a gargle in unhealthy ulcers of the mouth and fauces, a fluidounce to the pint; as a gargle in croup and diphtheritic angina with offensive breath, and as a wash for the hands after post-mortem examinations, two fluidounces to the pint. Of the same normal solution M. Reveil gives

from ten to thirty drops, ternally through the day, equivalent to from one to three grains. (*Arch. Gén.*, Janv. 1864, p. 25.) In preparing any solution of permanganate for use, it is of the utmost importance to avoid all organic matters; even the presence of matters of this kind adhering to the surface of unwashed bottles being often sufficient to render the solution unfit for disinfectant purposes.

Internally the medicine has been recommended in diabetes, by Mr. Sampson, of London; but experience has not confirmed the hopes that were at one time entertained of its efficiency. More recently we have been told that it has been used with supposed benefit, in cases of purulent infection, in the dose of half a grain or a grain repeated several times a day; and it is one of the remedies which is likely to prove useful in diphtheria, scarlatina, and other affections in which it may be presumed that noxious organic matters have entered the circulation. Dr. James F. Duncan has recently used it with encouraging success in acute rheumatism. He gives it in the form of Condy's disinfectant fluid, containing 9·26 grains in a fluidounce, of which he mixes one part with seven of distilled water, and administers half a fluidounce every two hours. (*Braithwaite's Retrosp.*, liv. 206.) Dr. Isaac Kay, of Springfield, Ohio, has found excellent effects from the permanganate in petechial fever, or spinal meningitis, giving a tablespoonful of a solution of one grain in an ounce of water, in other words half a grain of the salt, repeated every hour. (*Boston Med. and Surg. Journ.*, lxx. 373.) In diphtheria the remedy has proved extraordinarily successful, both given internally and applied locally, in the hands of Dr. Louis Mackall, Jr., of Georgetown, D. C. To a child of 11 years he gave a teaspoonful of a solution containing one drachm to a pint and a half of water. The solution for external use contained a drachm in a pint. (*Am. J. of Med. Sci.*, Jan. 1865, p. 87.)

Off. Prep. Liquor Potassæ Permanganatis, *Br.* W.

POTASSÆ SULPHAS. *U. S., Br.*

Sulphate of Potassa.

Sulphate of Potash. KO,SO_3. *Br.*

Vitriolated tartar; Tartarum vitriolatum, Arcanum duplicatum, Sal de duobus, *Lat.;* Sulfate de potasse, Potasse vitriolée, *Fr.;* Schwefelsaures Kali, Vitriolisirtir Weinstein *Germ.;* Solfato di potassa, *Ital.*

Several chemical processes give rise to sulphate of potassa as a secondary product. Thus, it is produced in the distillation of nitric acid from a mixture of nitre and sulphuric acid; in the decomposition of sulphate of magnesia by carbonate of potassa, in one of the processes for preparing carbonate of magnesia; in the manufacture of sulphuric acid; and in the decomposition of tartrate of potassa by sulphate of lime. When nitric acid is obtained by calcining a mixture of nitre and sulphate of iron, the residue consists of sesquioxide of iron and sulphate of potassa, the latter of which, being alone soluble, is separated by means of water, and crystallized from its solution. The impure sulphate of potassa with sulphur, forming the residue of the combustion of sulphur and nitre in making sulphuric acid, is employed in the manufacture of alum.

The U. S. Pharmacopœia places sulphate of potassa in the list of the Materia Medica; the British, among the preparations, obtaining it from the salt which remains after the distillation of nitric acid. This salt is a supersulphate of potassa, and must be so treated as to be brought to the neutral state. In the British process it is brought to that state by saturation, in boiling solution, with slaked lime. The solution is then filtered to separate the sulphate of lime, and carbonate of potassa is added at the boiling temperature to remove lime and sulphate of lime. It is again filtered, then either neutralized or rendered slightly acid with diluted sulphuric acid; and, finally, having been evaporated to a pellicle, is set aside for twenty-four hours to crystallize.

The manufacturer of tartaric acid who avails himself of sulphate of lime to decompose tartrate of potassa, forms sulphate of potassa as a collateral product.

For the manner in which the latter salt may be ... onomically crystallized for use in the arts, see *Am. Journ. of Pharm.* (xxiii. 343).

Properties. Sulphate of potassa is a white, anhydrous salt, in the form of small, aggregated, transparent, very hard crystals, permanent in the air, having the shape usually of short six-sided prisms, terminated by six-sided pyramids, and possessing a nauseous, somewhat bitter taste. Insoluble in alcohol, it is slowly soluble in about nine and a half times its weight of cold, and in less than four times its weight of boiling water. (*Gay-Lussac.*) Its solution is precipitated yellow by bichloride of platinum, and white by chloride of barium. Added to a solution of sulphate of alumina, it generates alum, recognised by the octohedral shape of its crystals. It is decomposed by tartaric acid, which forms bitartrate of potassa, and by the soluble salts of baryta, strontia, lime, silver, and lead, forming insoluble or sparingly soluble sulphates. This salt is not liable to adulteration. It consists of one eq. of sulphuric acid 40, and one of potassa $47{\cdot}2 = 87{\cdot}2$.

The *plate-sulphate of potassa*, so well described by Prof. Penny, of Glasgow, is, when pure, the double sulphate of potassa and soda, having the formula $3(KO,SO_3)+NaO,SO_3$. It is so called from the circumstance of being crystallized in hard thick cakes, or slabs, consisting of successive crops of crystals. It is a technical product from kelp, and may be formed by allowing successive quantities of concentrated kelp-ley to run into coolers, there to crystallize in successive layers; the mother-liquor being drawn off by a siphon, after the deposit of each layer. (*Philos. Mag.*, Dec. 1855.)*

* Potassæ Sulphas cum Sulphure. *Ed. Sulphate of Potassa with Sulphur. Sal Polychrestus Glaseri. Sal Polychrest.* This is an old preparation which was retained in the Edinburgh Pharmacopœia, but was omitted in the British, and consequently in the 12th edition of the present work. Its antiquity, however, if nothing else, entitles it to some notice; and the account given of it by Dr. Bache, in previous editions of the Dispensatory, is introduced here as a note.

It was prepared by mixing thoroughly equal parts of nitrate of potassa and sulphur, then throwing the mixture in small successive portions into a red-hot crucible; and, when the deflagration had ceased, and the salt had cooled, reducing it to powder, and keeping it in well-closed bottles.

When the mixture, indicated in this formula, is thrown into a red-hot crucible, each successive portion melts, and the sulphur floats on the surface of the nitre with the appearance of a brown oil, burns vividly, and gives rise to a copious evolution of sulphurous acid gas. The product of the deflagration is a grayish-white friable mass, intermixed apparently with undecomposed sulphur.

The nature of this preparation has not been well determined. On the supposition that it is the sulphate of potassa, mixed with a portion of sulphur, as the Edinburgh name implies, its formation may be thus explained. By the combined influence of the sulphur and of the heat employed, the nitric acid of the nitre is totally decomposed, and is thus enabled to furnish sufficient oxygen to convert a portion of the sulphur into sulphuric acid, which, as soon as formed, combines with the base of the nitre, to form the sulphate of potassa. This is left mixed with a portion of sulphur which has escaped combustion; but the greater part of the latter undergoes ordinary combustion, and is dissipated as sulphurous acid fumes.

Supposing the saline matter to be a sulphate containing a little free sulphur, this combustible is evidently used in great excess; but whether this excess is necessary to obtain the exact preparation desired by the Edinburgh College, it is not easy to determine. The late Dr. Duncan ascertained that the product amounted only to four-tenths of the materials employed. It is, therefore, smaller than it ought to be, even supposing that the residue consisted of nothing but sulphate of potassa.

Dr. Duncan was of opinion that the preparation under consideration cannot be viewed as a sulphuretted sulphate, and for the following satisfactory reasons. In the first place, it is more soluble in water than sulphate of potassa, and forms a yellowish solution, the water leaving undissolved only a small residue of a black colour, which is not sulphur. In the second place, it exhales during solution a sulphurous smell, and its taste is sulphurous. These facts seem to show that a small portion of sulphite of potassa is present in the preparation, or at least some sulphurous acid in a state of loose combination. It does not yield sulphuretted hydrogen on the addition of an acid, and is not precipitated by the salts of lead. These characters are inconsistent with the opinion of Mr. John Mackay, of Edinburgh, who believes that this preparation contains sulphuret of potassium. (See his remarks on it, in the *Pharm. Journ. and Trans.* for Jan. 1842.)

Properties, &c. This salt has an acid and sulphurous taste, and an acid reaction with

Medical Properties and Uses. Sulphate of potassa is a mild purgative, operating usually without heat, pain, or other symptom of irritation. In small doses of from a scruple to half a drachm, it operates as an aperient, and is useful in removing obstructions; in larger doses, of four or five drachms, it acts slowly as a purge. Combined with rhubarb, in the proportion of about a drachm of the salt to ten grains of the root, Dr. Fordyce recommended it as an excellent alterative cathartic in the visceral obstructions of children, characterized by a tumid abdomen, and defective digestion and nutrition; and we can bear testimony to its efficacy in such cases. The late Dr. A. T. Thomson found it, in combination with rhubarb or aloes, "more useful than any of the other saline purgatives in jaundice and dyspeptic affections." On the continent of Europe it is frequently given as an aperient after delivery, and for the purpose of drying up the milk. It enters into the composition of Dover's powder.

Notwithstanding the general sentiment of practitioners as to the safety of sulphate of potassa as a purgative, several cases are on record of supposed poisoning from its use. A case has been reported (1856), in which death was attributed to this salt, the amount taken having been estimated at an ounce and a half. M. Moritz attributed the poisonous effects of the salt, in a case under his notice, to the presence of a notable quantity of sulphate of zinc; but this explanation cannot be admitted as adequate. In other cases, the salt, though found to be pure, seemed to act as a poison. In these cases its effects may be attributed, sometimes to the largeness of the dose, and perhaps also to the insufficiency of water used to dissolve it; at other times, where the dose used was moderate, to the existence of a predisposition to gastric inflammation. For further information in relation to this subject, the reader is referred to a paper by the late Dr. T. Romeyn Beck, in the *Amer. Journ. of the Med. Sci.* (N. S., vii. 88).

POTASSII FERROCYANIDUM. *U. S.*

Ferrocyanide of Potassium.

Off. Syn. POTASSÆ PRUSSIAS FLAVA. *Yellow Prussiate of Potash.* $K_2FeC_6N_3+3HO$. A salt obtained by fusing animal substances, such as the cuttings of horns, hoofs, and skins, with carbonate of potash in an iron pot, lixiviating the crude product with water, and purifying the salt by crystallization. *Br.*

Ferrocyanuret of potassium, Ferrocyanate of potassa, Ferroprussiate of potassa, Prussiate of potassa; Proto-cyanure jaune de fer et de potassium, *Fr.;* Cyaneisenkalium, *Germ.*

It is the yellow double cyanide of potassium and iron, the salt from which cyanide of potassium is obtained by calcination at a low red heat.

Ferrocyanide of potassium is prepared on the large scale by heating animal matters, such as dried blood, hoofs, chips of horn, woollen rags, old leather, the refuse of tallow-chandlers called *greaves*, and other substances rich in nitrogen, with the pearlash of commerce and scrap iron, in an egg-shaped iron pot called a shell, ladling out the pasty mass called the *melt*, and, after it has cooled sufficiently, dissolving it in water, and evaporating the solution so that crystals may form. The melt, while still hot, contains cyanide of potassium only, the ferrocyanide being produced solely by the action of the water. The best temperature for making the solution is between 158° and 176°; and the conversion of the cyanide into the ferrocyanide is facilitated by the presence of finely divided

test paper. When pulverized, it yields a pale yellowish-white powder. It is soluble in eight times its weight of cold water. It is, however, not a uniform preparation; different specimens, apparently prepared with equal care, exhibiting some points of difference in properties. It was called by the earlier chemists *sal Polychrestus Glaseri*, or *sal Polychrest.* Its other properties coincide generally with those of sulphate of potassa, which may be considered as its basis.

Medical Properties and Uses. The medical effects of this preparation differ but little, if at all, from those of sulphate of potassa. Its action on the system is stated by Dr. Duncan to resemble that of the sulphurous mineral waters which contain a portion of neutral salt. The dose is from half a drachm to a drachm. B.

amorphous sulphuret of iron, and of caustic potassa. (A. Reimann, *Chem. Gaz.*, Jan. 1, 1855.)

Some years ago this salt was manufactured by a process which dispensed with the use of animal matter; the necessary nitrogen being obtained by a current of atmospheric air. Fragments of charcoal, impregnated with 30 per cent. of carbonate of potassa, were heated to white redness in a cylinder, through which a current of air was drawn by a suction pump. This process is understood to have succeeded in a chemical sense, but failed on the score of economy, chiefly from the circumstance that the necessary fire-clay tubes could not be made to resist the combined action of the alkali and heat. The process of Richard Brunnquell consists in passing ammonia through tubes, filled with charcoal and heated to redness, so as to form cyanide of ammonium, and converting this into ferrocyanide of potassium by contact with solution of potash and suitable iron compounds. (*Chem. Gaz.*, Nov. 1, 1856.)

Properties. Ferrocyanide of potassium is in large, beautiful, transparent, permanent, four-sided, tabular crystals, of a lemon-yellow colour, devoid of odour, but possessing a sweetish, yet somewhat bitter, saline taste. It dissolves in between three and four times its weight of cold water, and in about its own weight of boiling water, but is insoluble in alcohol. It acts but slightly, if at all, on turmeric paper. The alkaline reaction, when it exists, is probably owing to the presence of a little free potassa. When heated to 140° it loses its water of crystallization, amounting to 12·6 per cent., and becomes white. When ignited, the insoluble residue amounts to 18·7 per cent. of sesquioxide of iron, resulting from the oxidation of the iron of the salt. It is characterized by striking a deep-blue colour with the salts of sesquioxide of iron, a deep-brown one with the salts of copper, and a white one with those of zinc, the several precipitates formed being ferrocyanides of the respective metals. Heated with eight or ten times its weight of concentrated sulphuric acid, it evolves carbonic oxide. (*Fownes.*) Half an ounce of the salt yields about 250 cubic inches of the gas. (*C. Grimm and G. Ramdohr.*) When boiled with dilute sulphuric acid, it emits the smell of hydrocyanic acid. Ferrocyanide of potassium consists of two eqs. of cyanide of potassium 130·4, one of cyanide of iron 54, and three of water 27 = 211·4 (2KCy,FeCy + 3HO). The water present is just sufficient to convert the iron and potassium into protoxides, and the cyanogen into hydrocyanic acid. Apart from the water, it is generally considered to consist of a compound radical, called *ferrocyanogen*, formed of three eqs of cyanogen and one of iron (tercyanide of iron), united with two eqs. of potassium. Hence its officinal name. The salt is remarkably pure as it occurs in commerce.

Medical Properties, &c. Judging from the experiments of the German physicians, this salt possesses but little activity. Callies, as quoted by Pereira, found the commercial salt slightly poisonous, but the pure salt unproductive of harm in the dose of several ounces. It should be borne in mind that it is the commercial salt which is used medicinally. Westrumb and Hering proved that it passed with rapidity into the blood and urine. The late Dr. Burleigh Smart, of Kennebec, Maine, found it to possess active medical properties. (*Am. Journ. of Med. Sci.*, xv. 362.) Its primary effect was that of a sedative, diminishing the fulness and frequency of the pulse, and allaying pain and irritation. It acted also, under favourable circumstances, as a diaphoretic and astringent; but, as a diaphoretic, only in cases attended with excessive vascular action and increased heat of skin. As an astringent, its power was most conspicuous in the colliquative sweats of chronic bronchitis and phthisis. The same power was evinced in several cases of leucorrhœa. It sometimes produced ptyalism, unattended, however, by swelling of the salivary glands or fetor of the breath. Its properties as an anodyne and sedative rendered it applicable to cases of neuralgic pains and hooping-cough, in which diseases, especially the latter, Dr. Smart found it useful. When given in an overdose, it occasioned vertigo, coldness, and numbness, with a sense of gastric sinking. The form of administration which Dr. Smart preferred was that of solution, in the proportion of two drachms to the fluidounce

of water. Of this the dose for an adult is from 30 to 45 drops, equivalent to from 10 to 15 grains of the salt, repeated every four or six hours.

This salt is manufactured on a large scale, chiefly for the use of dyers and calico-printers. In pharmacy it is employed to prepare diluted hydrocyanic acid, Prussian blue, and the cyanides of potassium and silver.

PRINOS. *U. S. Secondary.*

Black Alder.

The bark of Prinos verticillatus. *U. S.*

PRINOS. *Sex. Syst.* Hexandria Monogynia. — *Nat. Ord.* Aquifoliaceæ.

Gen. Ch. Calyx small, six-cleft. *Corolla* monopetalous, subrotate, six-parted. *Berry* six-seeded; seeds nuciform. *Nuttall.*

Prinos verticillatus. Willd. *Sp. Plant.* ii. 225; Bigelow, *Am. Med. Bot.* iii. 141; Barton, *Med. Bot.* i. 203. The black alder is an indigenous shrub, with a stem six or eight feet high, furnished with alternate, spreading branches, and covered with a bluish-gray bark. The leaves, which stand alternately or irregularly on short petioles, are oval, pointed, tapering at the base, acutely serrate, of a dark green colour, smooth above, but downy on the veins beneath. The flowers are small, white, nearly sessile, and grow three or four together at the axils of the leaves. They are often diœcious. The calyx is persistent; the segments of the corolla obtuse; the stamens usually six, and furnished with oblong anthers; the germ large, green, and roundish, with a short style, terminating in an obtuse stigma. The fruit when ripe consists of glossy, scarlet, roundish berries, about the size of a pea, containing six cells and six seeds. Several of these berries are clustered, so as to form little bunches at irregular intervals on the stem. In the latter part of autumn, after the leaves have fallen, they still remain attached to the stem, and render the shrub a striking object in the midst of the general nakedness of vegetation. Hence the plant is often called *winterberry.*

It grows in all parts of the United States, from Canada to Florida, frequenting low wet places, such as swamps, and the borders of ponds, ditches, and streams. Its flowers appear in June. The berries, which have a bitter, sweetish, somewhat acrid taste, are sometimes used medicinally for the same purposes with the bark, which is the officinal portion.

The dried bark is in slender pieces, more or less rolled, brittle, greenish-white internally, and covered with a smooth epidermis, easily separable, and of a whitish-ash colour, alternating or mingled with brown. It has no smell, but a bitter and slightly astringent taste. Boiling water extracts its virtues.

Medical Properties and Uses. Black alder is usually considered tonic and astringent; and is among the remedies proposed as substitutes for Peruvian bark, with which, however, it has very little analogy. It has been recommended in intermittent fever, diarrhœa, and other diseases connected with debility, especially gangrene and mortification. It is a popular remedy in gangrenous or flabby and ill-conditioned ulcers, and in chronic cutaneous eruptions, in which it is given internally, and applied locally in the form of a wash or poultice. It may be used in substance or decoction. The dose of the powder is from thirty grains to a drachm, to be repeated several times a day. The decoction, which is usually preferred both for internal and external use, may be prepared by boiling two ounces of the bark with three pints of water to a quart, and given in the dose of two or three fluidounces. A saturated tincture, as well of the berries as of the bark, is sometimes employed. W.

PRUNUM. *U. S., Br.*

Prunes.

The dried fruit of Prunus domestica. *U. S.* The dried drupe of the Plum, Prunus domestica. From Southern Europe. *Br.*

Pruneaux, *Fr.;* Pflaumen, *Germ.;* Pruni, *Ital.;* Ciruelas secas, *Span.*

Prunus. *Sex. Syst.* Icosandria Monogynia. — *Nat. Ord.* Amygdaleæ.

Gen. Ch. Calyx inferior, bell-shaped, deciduous, with five obtuse, concave segments. *Petals* five, roundish, concave, spreading, larger than the segments of the calyx, into the rim of which they are inserted. *Filaments* awl-shaped, nearly as long as the corolla, from the rim of the calyx within the petals. *Anthers* short, of two round lobes. *Ovary* superior, roundish. *Style* of the length of the stamens. *Stigma* orbicular, peltate. *Drupe* roundish or elliptical. *Nut* hard, somewhat compressed, of one cell, and two more or less distinct sutures with an intermediate furrow. *Leaves* rolled up when young. (*Lindley.*)

Prunus domestica. Willd. *Sp. Plant.* ii. 995; Woodv. *Med. Bot.* p. 520, t. 187. The cultivated prune or plum tree is so well known as to render a minute description unnecessary. We merely give the specific character. "*Peduncles* subsolitary; *leaves* lanceolate-ovate, convolute; *branches* not spiny." The varieties of the tree produced by cultivation are very numerous. Nearly one hundred are to be found in the British gardens. Though at present growing wild in various parts of Europe, it is thought to have been brought originally from Asia Minor and Syria. It is the dried fruit only that is officinal.

The prunes brought to our market come chiefly from the south of France, the best from Bordeaux. They are derived from the variety of the tree named *Juliana* by Linnæus. The fresh fruit, called *Prune de Saint Julien* by the French, is of an oval shape, nearly an inch in length, and of a deep-violet colour. It is prepared by drying in the sun, after having been exposed to the heat of an oven. The finest prunes, used on the tables in France, are prepared from the larger kinds of plums, such as the *Saint Catharine,* and *Reine-Claude* or *green-gage.* An inferior sort is brought from Germany.

Prunes have a feeble odour, and a sweet mucilaginous taste, which is generally also somewhat acid. They contain uncrystallizable sugar, malic acid, and mucilaginous matter. In Germany a kind of brandy is obtained from them, which in some districts is largely consumed. Bonneberg, a German chemist, has extracted from prunes crystallizable sugar, equal to that of the cane.

Medical Properties and Uses. Prunes are laxative and nutritious, and, stewed with water, form an excellent diet in costiveness, especially during convalescence from febrile and inflammatory diseases. Imparting their laxative property to boiling water, they serve as a pleasant and useful addition to purgative decoctions. Their pulp is used in the preparation of laxative confections. Too largely taken, in a debilitated state of the digestive organs, they are apt to occasion flatulence, and griping pain in the stomach and bowels.

PRUNUS VIRGINIANA. *U. S.*

Wild-cherry Bark.

The bark of Cerasus serotina (*De Cand.*). *U. S.*

Cerasus. See LAURO-CERASUS.

This genus, which is now generally admitted, includes a large number of species formerly embraced in the genus Prunus of Linnæus.

Cerasus serotina. De Candolle, *Prodrom.* ii. 540; Torrey and Gray, *Flora of N. America,* i. 410. — *Cerasus Virginiana.* Michaux, *N. Am. Sylv.* ii. 205. According to Torrey and Gray, the name *Prunus Virginiana,* which has been wrongly applied to this species, was given by Linnæus to the *choke-cherry,* a

small tree or shrub, growing in the Northern States, and bearing a dark-red, globular, astringent fruit, about as large as that of the *wild-cherry*. This is described in the Flora of N. America of these authors, under the name of *Cerasus Virginiana*. The officinal species, or wild-cherry tree, is, according to Michaux, one of the largest productions of the American forest. Individuals were seen by that botanist on the banks of the Ohio, from eighty to one hundred feet high, with trunks from twelve to fifteen feet in circumference, and undivided to the height of twenty-five or thirty feet. But, as usually met with in the Atlantic States, the tree is much smaller. In the open fields it is less elevated than in forests, but sends out more numerous branches, which expand into an elegant oval summit. The trunk is regularly shaped, and covered with a rough, blackish bark, which detaches itself semicircularly in thick narrow plates. The leaves are oval-oblong, or lanceolate-oblong, acuminate, unequally serrate, smooth on both sides, of a beautiful brilliant green, and supported alternately upon petioles, which are furnished with from two to four reddish glands. The flowers are small, white, and collected in long erect or spreading racemes. They appear in May, and are followed by globular drupes, about the size of a pea, and when ripe of a shining blackish-purple colour.

This tree grows throughout the Union, flourishing most in those parts where the soil is fertile and the climate temperate, and abounding in the Middle Atlantic States, and in those which border on the Ohio. In the neighbourhood of Philadelphia, it affects open situations, growing solitarily in the fields and along fences, and seldom aggregated in woods or groves. It is highly valued by the cabinet-makers for its wood, which is compact, fine-grained, susceptible of polish, and of a light-red tint, which deepens with age. The leaves have been found by Prof. Procter to yield volatile oil and hydrocyanic acid on distillation, and in such proportion that a water distilled from them might with propriety be substituted for the cherry-laurel water. (*Proceed. of Am. Pharm. Assoc.*, 1858, p. 325.) The fruit has a sweetish, astringent, bitter taste; and is much used in some parts of the country to impart flavour to spirituous liquors. The inner bark is the part employed in medicine, and is obtained indiscriminately from all parts of the tree, though that of the roots is thought to be most active. Mr. J. S. Perot has ascertained that it is stronger when collected in autumn than in the spring. Thus, from a portion gathered in April he obtained 0·0478 per cent. of hydrocyanic acid, and from another in October 0·1436 per cent., or about three times as much. The parcels tried were taken from the same tree, and the same part of the tree. (*Am. Journ. of Pharm.*, xxiv. 111.) The bark should be preferred recently dried, as it deteriorates by keeping.

Properties. Wild-cherry bark, as kept in the shops, is in pieces of various sizes, more or less curved laterally, usually destitute of epidermis, of a lively reddish-cinnamon colour, brittle, and pulverizable, presenting a reddish-gray fracture, and affording a fawn-coloured powder. In the fresh state, or when treated with water, it emits an odour resembling that of peach leaves. Its taste is agreeably bitter and aromatic, with the peculiar flavour of the bitter almond. It imparts its sensible properties to water, either cold or hot, producing a clear reddish infusion closely resembling Madeira wine in appearance. Its peculiar flavour as well as medical virtues are injured by boiling, in consequence partly of the volatilization of the principles upon which they depend, partly upon a chemical change effected by the heat. From an analysis by Dr. Stephen Procter, it appears to contain starch, resin, tannin, gallic acid, fatty matter, lignin, red colouring matter, salts of lime and potassa, and iron. He obtained also a volatile oil, associated with hydrocyanic acid, by distilling the same portion of water successively from several different portions of the bark. This oil was of a light-straw colour, and very analogous in its properties to the volatile oil of bitter almonds. In the quantity of two drops it proved fatal to a cat in less than five minutes. (*Journ. of the Philad. Col. of Pharm.*, vi. 8.) Prof. William Procter proved that, as in the case of bitter almonds, the volatile oil and hydrocyanic acid do not exist ready formed in the bark, but are the result of the reaction of

water with amygdalin, which he ascertained to be one of its constituents. In order, however, that this change may take place, the agency of another principle, probably analogous to if not identical with *emulsin* or the *synaptase* of Robiquet, is also essential; and, as this principle becomes inoperative at the boiling temperature, we can understand how decoction may interfere with the virtues of the bark. (*Am. Journ. of Pharm.*, x. 197.) The conjecture was advanced, in former editions of this work, that wild-cherry bark might contain also *phloridzin*, a bitter principle proved to exist in the bark of the apple, pear, cherry, and plum trees; but Mr. Perot sought for this principle, without success, in specimens of the bark of different ages, and taken from different parts of the tree; so that the tonic property, which is undoubtedly possessed by the bark, must reside either in the portion of amygdalin which may remain undecomposed, in the pure volatile oil resulting from its reaction with water, or in some yet undiscovered principle. (*Ibid.*, xxiv. 111.) That the last of these inferences is the correct one, would seem to be proved by an experiment by Prof. Procter, who found the bitterness of an extract of the bark to remain after it had been wholly deprived of amygdalin. (See the author's *Treatise on Therapeutics, &c.*, i. 291.) The sedative properties of the bark depend upon the hydrocyanic acid which it yields.

Medical Properties and Uses. This bark is among the most valuable of our indigenous remedies. Uniting with a tonic power the property of calming irritation and diminishing nervous excitability, it is admirably adapted to the treatment of diseases in which debility of the stomach, or of the system, is united with general or local irritation. When largely taken it diminishes the action of the heart, an effect ascribable to the hydrocyanic acid. Dr. Eberle found copious draughts of the cold infusion, taken several times a day, and continued for nearly two weeks, to reduce his pulse from seventy-five to fifty strokes in the minute. The remedy is highly useful, and has been much employed in this country, in the hectic fever of scrofula and consumption. In the general debility which often succeeds inflammatory diseases, it is also advantageous; and it is well adapted to many cases of dyspepsia. It has been given successfully in intermittent fever, but is much inferior to cinchona.

It may be used in the form of powder, infusion, fluid extract, or syrup. The dose of the powder is from thirty grains to a drachm; of the infusion, which is properly directed in the Pharmacopœia to be prepared with cold water, two or three fluidounces; of the fluid extract, a fluidrachm; and of the syrup, half a fluidounce. These preparations are all officinal, and are described in the second part of the work, under their titles respectively.

PYRETHRUM. *U. S. Secondary.*

Pellitory.

The root of Anacyclus Pyrethrum. *U. S.*

Off. Syn. PYRETHRI RADIX. *Pellitory Root.* The root of Anacyclus Pyrethrum. *Br.*

Pyrèthre, *Fr.;* Bertram Wurzel, *Germ.;* Piretro, *Ital.;* Pelitre, *Span.*

ANACYCLUS. Differing from Anthemis by its winged and obcordate *achenia*. *Lindley.* See ANTHEMIS.

Anacyclus Pyrethrum. De Cand. *Prodrom.* vi. 15. — *Anthemis Pyrethrum.* Willd. *Sp. Plant.* iii. 2184; Woodv. *Med. Bot.* p. 50, t. 20. The root of this plant is perennial, and sends up numerous stems, usually trailing at the base, erect in their upper portion, eight or ten inches high, and terminated by one large flower. The leaves are doubly pinnate, with narrow nearly linear segments of a pale-green colour. The florets of the disk are yellow; the rays white on their upper surface, and reddish or purple beneath and at their edges.

The plant is a native of the Levant, Barbary, and the Mediterranean coast

of Europe. The root is the part used under the name of pellitory, or *pellitory of Spain*. According to Hayne, the pellitory of the shops is derived from the *Anacyclus officinarum*, a plant cultivated in Thuringia for medical purposes. This remark, however, can apply only to Germany.

Properties. The dried root of *A. Pyrethrum* is about the size of the little finger, cylindrical, straight or but slightly curved, wrinkled longitudinally, of an ash-brown colour externally, whitish within, hard and brittle, and sometimes furnished with a few radicles. It is destitute of odour, though, when fresh, of a disagreeable smell. Its taste is peculiar, slight at first, but afterwards acidulous, saline, and acrid, attended with a burning and tingling sensation over the whole mouth and throat, which continues for some time, and excites a copious flow of saliva. Its analysis by Koene gives, in 100 parts, 0·59 of a brown, very acrid substance, of a resinous appearance, and insoluble in caustic potassa; 1·06 of a dark-brown, very acrid fixed oil, soluble in potassa; 0·35 of a yellow acrid oil, also soluble in potassa; traces of tannin; 9·40 parts of gum; inulin; 7·60 parts of sulphate and carbonate of potassa, chloride of potassium, phosphate and carbonate of lime, alumina, silica, &c.; and 19·80 of lignin, besides loss. (See *Am. Journ. of Pharm.*, viii. 175.)

Medical Properties and Uses. Pellitory is a powerful irritant, used almost exclusively as a sialagogue in certain forms of headache, rheumatic and neuralgic affections of the face, toothache, &c., or as a local stimulant in palsy of the tongue or throat, and in relaxation of the uvula. For these purposes it may be chewed, or employed as a gargle in decoction or vinous tincture. The dose as a masticatory is from thirty grains to a drachm. An alcoholic extract is sometimes employed by dentists as a local application to carious teeth, with a view to its benumbing effect before plugging.

Off. Prep. Tinctura Pyrethri, *Br.* W.

QUASSIA. *U. S.*

Quassia.

The wood of Simaruba excelsa. *U. S.*

Off. Syn. QUASSIÆ LIGNUM. *Quassia Wood.* The wood of Picræna excelsa. *Br.*

Bois de quassie, *Fr.;* Quassienholz, *Germ.;* Legno della quassia, *Ital.;* Leno de quassia, *Span.*

QUASSIA. *Sex. Syst.* Decandria Monogynia. — *Nat. Ord.* Simarubaceæ.

Gen. Ch. Calyx five-leaved. *Petals* five. *Nectary* five-leaved. *Drupes* five, distant, bivalve, one-seeded, inserted into a fleshy receptacle. *Willd.*

Of the species included by Linnæus in this genus, some, as *Quassia amara*, are hermaphrodite; others, as *Q. excelsa* and *Q. Simaruba*, are monœcious or polygamous. The latter have been associated by De Candolle in a distinct genus, named *Simaruba*, which has been again divided by Lindley into *Simaruba* with monœcious, and *Picræna* with polygamous flowers. To the last-mentioned genus the proper Quassia plant, Q. excelsa of Linnæus, belongs.

The medicine was formerly obtained from *Quassia amara;* but more than twenty years since Lamarck stated that, in consequence of the scarcity of this tree, *Quassia excelsa* had been resorted to as a substitute, and the Pharmacopœias at present agree in acknowledging the latter as the officinal plant. The genuine quassia plant, however, of Surinam is the *Q. amara;* and we shall, therefore, give a brief description of both species.

Quassia excelsa. Willd. *Sp. Plant.* ii. 569. — *Simaruba excelsa.* De Cand. *Prodrom.* i. 733; Hayne, *Darstel. und Beschreib.* &c. ix. 16. — *Picræna excelsa.* Lindley, *Flor. Med.* 208. As its name imports, this is a lofty tree, attaining sometimes not less than one hundred feet in height, with a straight, smooth, tapering trunk, which is often three feet in diameter near its base, and covered with a smooth, gray bark. The leaves are pinnate, with a naked petiole, and oblong pointed leaflets standing upon short footstalks, in opposite pairs, with a

single leaflet at the end. The flowers are small, of a yellowish-green colour, and disposed in panicles. They are polygamous and pentandrous. The fruit is a small black drupe. This species inhabits Jamaica and the Caribbean islands, where it is called *bitter ash*. The wood is the officinal portion.

Quassia amara. Willd. *Sp. Plant.* ii. 567; Woodv. *Med. Bot.* p. 574, t. 204. The bitter quassia is a small branching tree or shrub, with alternate leaves, consisting of two pairs of opposite pinnæ, with an odd one at the end. The leaflets are elliptical, pointed, sessile, smooth, of a deep-green colour on their upper surface, and paler on the under. The common footstalk is articulated, and edged on each side with a leafy membrane. The flowers, which are hermaphrodite and decandrous, are bright red, and terminate the branches in long racemes. The fruit is a two-celled capsule containing globular seeds. Quassia amara is a native of Surinam, and is said also to grow in some of the West India islands. Its root, bark, and wood were formerly officinal. They are excessively bitter, as in fact are all parts of the plant. It is uncertain whether any of the produce of this tree now reaches our markets.

Quassia comes in cylindrical billets of various sizes, from an inch to near a foot in diameter, and several feet in length. These are frequently invested with a light-coloured smoothish bark, brittle, and but slightly adherent, and possessing in at least an equal degree the virtues of the wood. Their shape and structure clearly evince that they are derived from the branches or trunk, and not, as some have supposed, from the root of the tree. In the shops they are usually kept split into small pieces, or rasped.*

Properties. The wood is at first whitish, but becomes yellow by exposure. It is inodorous, and has a purely bitter taste, surpassed by that of few other substances in intensity and permanence. It imparts its active properties, with its bitterness and yellow colour, to water and alcohol. Its virtues depend upon a peculiar bitter crystallizable principle, denominated *quassin*, which was first discovered by Winckler. It may be obtained pure by the following process of Wiggers. A filtered decoction of quassia is evaporated to three-quarters of the weight of the wood employed, slaked lime is added, and the mixture, having been allowed to stand for a day, with occasional agitation, is again filtered. A considerable quantity of pectin, besides other substances, is thus separated. The clear liquor is evaporated nearly to dryness, and the resulting mass exhausted by alcohol of the sp. gr. 0·835, which leaves behind gum, common salt, nitre, &c., in large amount, and dissolves quassin with some common salt and nitre, and a brown organic substance. In order to separate the quassin from these latter principles, which are soluble in water, the solution is evaporated to dryness, the resulting mass is dissolved in the least possible quantity of absolute alcohol, a large proportion of ether is added, and the liquor, previously separated by filtration from the brown mass which the ether has thrown down, is evaporated to dryness; and this process is repeated till the quassin remains behind quite colourless, and affords no evidence of the presence of the above-mentioned salts. Lastly, in order to obtain it in a crystalline form, to which it is not strongly disposed, pour the alcoholic solution mixed with ether upon a little water, and allow it to evaporate spontaneously. *Quassin* is white, opaque, unalterable in the air, inodorous, and of an intense bitterness, which in the solutions of this principle is almost insupportable. The bitterness is pure, and resembles that of the wood. When heated, quassin melts like a resin. It is but slightly soluble in water, 100 parts of which at 54° dissolve only 0·45, and that slowly. By the addition of salts, especially of those with which it is associated

* Mr. Edward Parrish has called attention to a bark, known in the market under the name of *quassia bark*. (*Am. Journ. of Pharm.*, xxix. 104.) A specimen in our possession is in pieces, very broad, slightly curved laterally, thin in proportion to their other dimensions, covered with a thin, greenish-brown, rough epidermis, yellowish-white and striated on their inner surface, of a feeble odour, and a quassia-like bitterness. The inner layers of the proper bark are very fibrous and tough, and, on the broken surface, of a light-yellow colour. It is uncertain whether the bark is from the Quassia excelsa; but there is little doubt that it is either from that or some analogous tree. (*Note to the eleventh edition.*)

in quassia, its solubility is strikingly increased. It is also but slightly soluble in ether, but is very soluble in alcohol, more so in that liquid hot than cold, and the more so the purer it is. Quassin is perfectly neuter, though both alkalies and acids increase its solubility in water. It is precipitated by tannic acid from its aqueous solution, which is not disturbed by iodine, chlorine, corrosive sublimate, the salts of iron, sugar of lead, or even subacetate of lead. Its ultimate constituents are carbon, hydrogen, and oxygen. Among the salts contained in quassia, Mr. Geo. Whipple has detected a considerable proportion of sulphate of soda. (*Pharm. Journ.*, xiii. 643.)

Medical Properties and Uses. Quassia has in the highest degree all the properties of the simple bitters. It is purely tonic, invigorating the digestive organs, with little excitement of the circulation, or increase of animal heat. It has not been very long known as a medicine. About the middle of the last century, a negro of Surinam, named Quassi, acquired considerable reputation in the treatment of the malignant fevers of that country, by a secret remedy, which he was induced to disclose to Mr. Rolander, a Swede, for a valuable consideration. Specimens were taken to Stockholm by this gentleman in the year 1756; and the medicine soon became popular in Europe. The name of the negro has been perpetuated in the generic title of the plant. But the quassia of Surinam is not now in use, having been superseded by the product of Quassia excelsa, from the West Indies. This medicine is useful whenever a simple tonic impression is desirable. It is particularly adapted to dyspepsia, and to that debilitated state of the digestive organs which sometimes succeeds acute disease. It may also be given with advantage in the remission of certain fevers in which tonics are demanded. No one at present would expect from it any peculiar controlling influence over malignant fevers. It is said to be largely employed in England by the brewers, to impart bitterness to their liquors.

It is most conveniently administered in infusion or extract. (See *Infusum Quassiæ* and *Extractum Quassiæ*.) The difficulty of reducing the wood to powder is an objection to its use in substance. It may, however, be employed in a dose varying from a scruple to a drachm, repeated three or four times a day. Some dyspeptic patients, who have become habituated to its bitterness, chew the wood occasionally with benefit.

This genus comprises not less than eighty species, of which between thirty and forty are within the limits of the United States. Many of these are applied to important practical purposes. In the northern hemisphere, the oak is the most

valuable, as it is the most widely diffused of all forest trees. Notwithstanding the great number of species, few, comparatively, have found a place in the officinal catalogues. *Q. robur*, or common European oak, was formerly recognised by the British Colleges; but at present only *Q. pedunculata*, or European white oak, is admitted in the Br Pharmacopœia. As these do not grow in the United States, and their products are not imported, it is unnecessary to treat of them particularly in this work. According to Michaux, they grow in the same countries, frequently together, constituting the greater part of the forests of Europe, and spreading over almost the whole northern section of Asia, and the northern coast of Africa. *Q. pedunculata* is the common British oak, celebrated as well for its majestic growth, and the venerable age which it attains, as for the strength and durability of its timber. Our own Pharmacopœia recognises only *Q. alba* or white oak, and *Q. tinctoria* or black oak; but other species afford barks equally useful, and perhaps as much employed. Such are *Q. falcata* or Spanish oak, *Q. prinus* or white chestnut oak, and *Q. montana* or rock chestnut oak. The following remarks in relation to white-oak bark will apply also to that of the three last-mentioned species. The bark of *Q. tinctoria* is somewhat peculiar.

1. *Quercus alba.* Willd. *Sp. Plant.* iv. 448; Michaux, *N. Am. Sylv.* i. 17. Of all the American species, the *white oak* approaches nearest, in the character of its foliage, and the properties of its wood and bark, to *Q. pedunculata* of Great Britain. When allowed to expand freely in the open field, it divides at a short distance from the ground into numerous widely spreading branches, and attains under favourable circumstances a magnificent size. Its trunk and large branches are covered with a whitish bark, which serves to distinguish it from most of the other species. The leaves are regularly and obliquely divided into oblong, obtuse, entire lobes, which are often narrowed at their base. When full grown, they are smooth and light-green on their upper surface, and glaucous beneath. Some of the dried leaves remain on the tree during the whole winter. The acorns are large, ovate, contained in rough, shallow, grayish cups, and supported singly or in pairs upon peduncles nearly an inch in length.

The white oak abounds in the Middle States, and extends also through the whole Union, though comparatively rare in the northern, southern, and western sections. It is the most highly valued for its timber of all the American oaks, except the *live oak* (*Q. virens*), which is preferred in ship-building. The bark is sometimes used for tanning, but that of the *red* and *Spanish oaks* is preferred. All parts of the tree, with the exception of the epidermis, are more or less astringent, but this property predominates in the fruit and bark.

White-oak bark, deprived of its epidermis, is of a light-brown colour, of a coarse, fibrous texture, and not easily pulverized. It has a feeble odour, and a rough, astringent, and bitterish taste. Water and alcohol extract its active properties. The chief soluble ingredients are tannin, gallic acid, and extractive matter. It is upon the tannin that its medical virtues, as well as its use in the preparation of leather, chiefly depend. The proportion of this ingredient varies with the size and age of the tree, the part from which the bark is derived, and even the season when it is gathered. It is most abundant in the young bark; and the English oak is said to yield four times as much in spring as in winter. Sir H. Davy found the inner bark most abundant in tannin, the middle portion or cellular integument much less so, and the epidermis almost wholly destitute as well of this principle as of extractive.

Gerber discovered, in European oak bark, a peculiar bitter principle upon which he conferred the name of *quercin*. It is obtained by boiling the bark with water acidulated with one hundredth of sulphuric acid, adding first milk of lime until the sulphuric acid is removed, and then a solution of carbonate of potassa so long as a white precipitate is produced, filtering the liquor, evaporating to the consistence of a thin extract, adding alcohol, and finally evaporating the spirituous solution down to a small volume, and allowing it to rest for some days. Yellow crystals form, which may be obtained colourless by repeated crystallizations. Quercin is a neuter principle, in small, white crystals, inodorous, very bitter.

readily soluble in water, less so in alcohol containing water, and insoluble in absolute alcohol, ether, and oil of turpentine. (*Arch. der Pharm.*, xxxiv. 167.)

2. *Quercus tinctoria.* Willd. *Sp. Plant.* iv. 444; Michaux, *N. Am. Sylv.* i. 91. The *black oak* is one of our largest trees, frequently attaining the height of eighty or ninety feet. Its trunk is covered with a deeply furrowed bark, of a black or dark-brown colour. The leaves are ovate-oblong, pubescent, slightly sinuated, with oblong, obtuse, mucronate lobes. The fructification is biennial. The acorn is globose, flattened at top, and placed in a saucer-shaped cup.

Black-oak bark has a more bitter taste than that of the other species, and may be distinguished also by staining the saliva yellow when it is chewed. Its cellular integument contains a colouring principle, capable of being extracted by boiling water, to which it imparts a brownish-yellow colour, which is deepened by alkalies and rendered brighter by acids. Under the name of *quercitron*, large quantities of this bark, deprived of its epidermis and reduced to coarse powder, are sent from the United States to Europe, where it is used for dyeing wool and silk of a yellow colour. The colouring principle is called *quercitrin*, or, from its property of combining with salifiable bases, *quercitric acid*. It was discovered by M. Chevreul; and its properties have been investigated by MM. Bolley and Rigaud. These chemists obtained it by forming a tincture of the bark with alcohol of the sp. gr. 0·849, freeing this from tannin and a brown substance by gelatin, distilling off the alcohol, and replacing it as it was evaporated by water. The quercitrin was deposited, and afterwards purified by repeated solution in alcohol, and separation by water as before. Thus procured, it is yellow, slightly bitter, inodorous, in microscopic crystals of the right-rhombic system, soluble in 425 parts of boiling water (Rigaud), almost insoluble in cold water, sparingly soluble in ether, and freely soluble in alcohol and alkaline solutions. Its formula is given as $C_{36}H_{19}O_{20}$. (*Chem. Gaz.*, no. 290, p. 428.)* According to Rigaud, quercitrin is a glucoside, being resolvable into glucose, and a neuter substance which he calls *quercetin*. (*Journ. de Pharm.*, Janv. 1860, p. 76.) Besides this principle, the bark contains much tannin; but it is less used in tanning than the other barks, in consequence of the colour which it imparts to the leather.

Medical Properties and Uses. Oak bark is astringent and somewhat tonic. It has been given with advantage in intermittent fever, obstinate chronic diarrhœa, and certain forms of passive hemorrhage; but it is not much employed as an internal remedy. Externally applied it is often productive of benefit. The decoction may be advantageously used as a bath, particularly for children, when a combined tonic and astringent effect is desirable, and the stomach is not disposed to receive medicines kindly. It has been employed in this way in marasmus, scrofula, intermittent fevers, chronic diarrhœa, and cholera infantum. As an injection in leucorrhœa, a wash in prolapsus ani and hemorrhoidal affections, and as a gargle in slight inflammation of the fauces, attended with prolapsed uvula, the decoction is often useful. It has also been recommended as an injection into dropsical cysts. Reduced to powder and made into a poultice, the bark was recommended by the late Prof. Barton as an excellent application in external gangrene and mortification; and the infusion obtained from tanners' vats has been used beneficially as a wash for flabby, ill-conditioned ulcers. The bark may be given in the form of powder, extract, or decoction. The dose of the powder is from thirty grains to a drachm, of the extract about half as much, of the decoction two fluidounces. (See *Decoctum Quercûs*.)

Black-oak bark is considered inferior to the white-oak bark as an internal remedy, in consequence of being more disposed to irritate the bowels.

Acorns, besides the bitter and astringent principles of the bark, contain a peculiar saccharine matter (*quercite*), which is insusceptible of the vinous fer-

* Quercitrin has been found also in various other plants; as in the leaves of Ruta graveolens, and the flower-buds of Capparis spinosa, Sophora Japonica, and Æsculus Hippocastanum or horse-chestnut. (*Chem. Gaz.*, May 2, 1859, p. 161.) As this principle is capable of assuming various colours under various chemical influences, the idea has been advanced that it might be the colouring principle of flowers. (*Am. Journ. of Pharm.*, May, 1860, p. 222.)

mentation. (*Journ. de Pharm.*, 3e sér., xx. 335.) They are sometimes used as a tonic or astringent; and a decoction made from roasted acorns has been long employed in Germany as a remedy in scrofula. Before roasting they should be deprived of their shells; and the cotyledons, according to Dausse, should lose, during the process, 140 parts of their weight out of 500. (*Pharm. Cent. Blatt*, Oct. 9, 1850, p. 687.) From half an ounce to an ounce may be prepared as coffee, and the whole taken at breakfast with cream and sugar. (*Richter.*)

RANUNCULUS. *U. S. Secondary.*

Crowfoot.

The cormus and herb of Ranunculus bulbosus. *U. S.*

Ranunculus. *Sex. Syst.* Polyandria Polygynia. — *Nat. Ord.* Ranunculaceæ.

Gen. Ch. Calyx five-leaved. *Petals* five, having the inner side of each claw furnished with a melliferous pore. *Seeds* naked, numerous. *Nuttall.*

Most of the plants belonging to this genus have the same acrid properties. Several of them grow together in our fields and pastures, and, from their close resemblance, are confounded under the common name of *butter-cup*, applied to them from the colour and shape of their flowers. Those which are most abundant are believed to have been introduced from Europe. Such are *R. bulbosus*, *R. acris*, and *R. repens*, which, with *R. sceleratus*, may be indiscriminately used. In Europe, *R. sceleratus* appears to have attracted most attention; in this country, *R. bulbosus*. The latter is the only one designated by our Pharmacopœia. *R. acris* and *R. Flammula* were formerly directed by the Dublin College, but have been discarded in the Br. Pharmacopœia.

Ranunculus bulbosus. Willd. *Sp. Plant.* ii. 1324; Bigelow, *Am. Med. Bot.* iii. 60. This species of crowfoot is perennial, with a solid, fleshy root (cormus), and several annual, erect, round, and branching stems, from nine to eighteen inches high. The radical leaves, which stand on long footstalks, are ternate or quinate, with lobed and dentate leaflets. The leaves of the stem are sessile and ternate, the upper more simple. Each stem supports several solitary, bright-yellow, glossy flowers, upon furrowed, angular peduncles. The leaves of the calyx are reflexed, or bent downwards against the flowerstalk. The petals are obcordate, and arranged so as to resemble a small cup. At the inside of the claw of each petal is a small cavity, covered with a minute wedge-shaped emarginate scale. The fruit consists of numerous naked seeds, in a spherical head. The stem, leaves, peduncles, and calyx are hairy.

In May and June our pastures are everywhere adorned with the rich yellow flowers of this species of Ranunculus. Somewhat later *R. acris* and *R. repens* begin to bloom, and a succession of similar flowers is maintained till September. The two latter species prefer a moister ground, and are found most abundantly in meadows. *R. sceleratus* frequents ponds and ditches. In all these species, the whole plant is pervaded by a volatile acrid principle, which is dissipated by drying or by heat, and may be separated by distillation. Dr. Bigelow found that water distilled from the fresh plant had an acrid taste, and produced when swallowed a burning sensation in the stomach; and that it retained these properties for a long time, if kept in closely-stopped bottles. Dr. Clarus discovered, in R. sceleratus, besides the acrid volatile oil, a nearly inert resin, and a narcotic principle called *anemonin*. The volatile oil is soluble in ether, and is decomposed, on standing, into a white amorphous substance having acid properties (*anemonic acid*), and into anemonin. Other species of Ranunculus probably have the same constituents. (*B. and F. Med.-chir. Rev.*, Jan. 1859, p. 181.) The plant itself, when chewed, excites violent irritation in the mouth and throat; inflaming and even excoriating the tongue and inside of the cheeks and lips, if not quickly discharged. Both the root and herb of *R. bulbosus* are officinal.

Medical Properties and Uses. Crowfoot, when swallowed in the fresh state,

produces heat and pain in the stomach, and, if the quantity be considerable, may excite fatal inflammation. Dr. Clarus states that it has also narcotic properties, diminishing the frequency of the pulse and respiration, and producing palsy of the extremities. These properties he ascribes to the anemonin It is, however, never used internally; though the juice and distilled water of some species of Ranunculus are said to act as a prompt and powerful emetic. The property for which it has attracted the attention of physicians is that of inflaming and vesicating the skin; and, before the introduction of the Spanish fly into use, it was much employed for this purpose. But the uncertainty and occasional violence of its action have nearly banished it from regular practice. While on some individuals it appears to produce scarcely any effect; on others it acts very speedily, exciting extensive and troublesome inflammation, which sometimes terminates in deep, obstinate ulcers. It probably varies in strength with the season; and, in the dried state, or boiled with water, is wholly inert. The decoction, moreover, is inert in consequence of the escape of the acrid principle. Nevertheless, the plant has been very properly retained in the Pharmacopœia, in the catalogue of medicines of secondary importance; as occasions may happen, when the practitioner in the country may find advantage in having recourse to its powerful rubefacient and epispastic operation. W.

RESINA. *U. S., Br.*

Resin.

The residue after the distillation of the volatile oil from the turpentine of Pinus palustris and other species of Pinus. *U. S.* The residue of the distillation of the turpentines from various species of Pinus and Abies. *Br.*

Résine blanche, Résine jaune, *Fr.;* Fichtenharz, *Germ.;* Ragea di pino, *Ital.;* Resina de pino, *Span.*

After the distillation of the volatile oil from the turpentines (see *Terebinthina*), a resinous matter remains, which on the continent of Europe is called *colophony*, but with us is commonly known by the name of *rosin*. It is the Resina of the U. S. and Br. Pharmacopœias. It is sometimes called *resina flava* or *yellow resin*. When this, in a state of fusion, is strongly agitated with water, it acquires a distinct appearance, and is denominated *resina alba* or *white resin*. Before describing this officinal, it may be proper to enumerate the characteristic properties of the proximate principles denominated resins.

Resins are solid, brittle, of a smooth and shining fracture, and generally of a yellowish colour and semitransparent. When perfectly pure, they are probably inodorous and often insipid; but, as usually found, they have a slight odour, and a somewhat acrid or bitterish taste. Their sp. gr. varies from 0·92 to 1·2. They are fusible by a moderate heat, decomposed at a higher temperature, and in the open air take fire, burning with a yellow flame and much smoke. Insoluble in water, they are dissolved by ether and the volatile oils, and generally by alcohol; and their alcoholic and ethereal solutions afford precipitates upon the addition of water. With pure potassa and soda they unite to form soaps, which are soluble in water; and the same result takes place when they are heated with solutions of the alkaline carbonates. Concentrated sulphuric acid dissolves them with mutual decomposition; and nitric acid converts them into artificial tannin. They readily unite by fusion with wax and the fixed oils.*

Common or *yellow resin*, in its purest state, is beautifully clear and pellucid, but much less so as usually found in the shops. Its odour and taste are generally in a slight degree terebinthinate; its colour yellowish-brown with a tinge of olive,

* M. Losch recommends the following process for rendering the resins as white as possible. Boil together 5 parts of the resin, 1 of carbonate of potassa or of soda, and 20 of water, until a perfectly homogeneous mass is obtained; allow this to cool, and pass into it sulphurous acid, which saturates the alkali, and precipitates the resin in white flakes. Finally, wash the precipitate well with water, and dry it. (*Journ. de Pharm.*, Juin, 1856, p. 465.)—*Note to the eleventh edition.*

and more or less dark according to its purity, and the degree of heat to which it has been exposed in its preparation. Sometimes it is almost black. It is rather heavier than water. At 276° F. it melts, is completely liquid at 306°, begins to emit bubbles of gas at 316°, and is entirely decomposed at a red heat. Its ultimate constituents are carbon, hydrogen, and oxygen, in variable proportions. It appears, from the researches of Unverdorben, to contain three distinct resinous bodies, two of which, denominated *pinic* and *sylvic acids*, pre-existed in the turpentine, and the third, called *colophonic acid*, is formed by the agency of heat in the distillation. The *pinic acid* is dissolved by cold spirit of the sp. gr. 0·865, and is thus separated from the sylvic acid. It is obtained pure by adding to the solution a spirituous solution of acetate of copper, dissolving the precipitated pinate of copper in strong boiling alcohol, decomposing this salt with a little muriatic acid, and adding water, which throws down the pinic acid as a resinous powder. The *sylvic acid* is obtained by treating the residue of the common resin with boiling spirit of 0·865, which dissolves it, and lets it fall upon cooling. Both of these resinous acids are colourless. Pinic acid is soluble in weak cold alcohol; sylvic acid is insoluble in the same menstruum when cold, but is dissolved by it when boiling hot, and by strong alcohol at all temperatures. The salts which they form with the alkalies are soluble, those with the earths and metallic oxides, insoluble in water. *Colophonic acid* differs from the others in having stronger acid properties, and in being less soluble in alcohol. It is of a brown colour; and common resin is more or less coloured in proportion to the quantity of this acid which it contains. (*Kane's Chemistry.*) The experiments of Unverdorben were made with European colophony. It is somewhat uncertain whether exactly the same results would be afforded by the common resin of this country, which is obtained from a different species of pine. By the destructive distillation of resin an oleaginous product is obtained, called *resin oil*, which in various degrees of purity is used in currying leather, lubricating machinery, preparing printers' ink, &c.

White resin differs from the preceding only in being opaque and of a whitish colour. These properties it owes to the water with which it is incorporated, and which gradually escapes upon exposure, leaving it more or less transparent.

Medical Uses. Resin is important as an ingredient of ointments and plasters, but is never used internally. According to Professor Olmsted, it has the property of preventing the oxidation of fatty substances, and thus contributes to the preservation of ointments. (*Am. Journ. of Pharm.*, xxii. 325.)

RHAMNI SUCCUS. *Br.*

Buckthorn Juice.

The recently expressed juice of the ripe berries of common Buckthorn, Rhamnus catharticus. *Br.*

The juice of Rhamnus catharticus, recognised by the London College, was rejected by the framers of the first British Pharmacopœia, but has been restored to its officinal rank in the last edition; and, therefore, claims consideration again in this part of the U. S. Dispensatory, from which it was transferred in the twelfth edition to the third part, as not at that time belonging to either of the officinal lists. The berries were directed by the Edinburgh College.

Rhamnus. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Rhamnaceæ.

Gen. Ch. "*Calyx* tubular. *Corolla* scales defending the stamens, inserted into the calyx. *Berry.*" (*Willd.*)

Rhamnus catharticus. Willd. *Sp. Plant.* i. 1092; Woodv. *Med. Bot.* p. 594

t. 210. The purging buckthorn is a shrub seven or eight feet high, with branches terminating in a sharp spine. The leaves are in fascicles, on short footstalks, ovate, serrate, veined. The flowers are usually dicœcious, in clusters, small, greenish, peduncled, with a four-cleft calyx, and four very small scale-like petals, placed in the male flower, behind the stamens, which equal them in number. The fruit is a four-seeded berry. The shrub is a native of Europe, and has been found growing wild in this country. It was first discovered in the Highlands of New York by Dr. Barratt. (*Eaton's Manual.*) It flowers in May and June, and ripens its fruit in the latter part of September. The berries and their juice are used. When ripe they are of the size of a pea, round, somewhat flattened at top, black, smooth, shining, with four seeds in a green, juicy parenchyma. Their odour is unpleasant, their taste bitterish, acrid, and nauseous. The expressed juice has the colour, odour, and taste of the parenchyma. It is reddened by the acids, and from deep-green is rendered light-green by the alkalies. Upon standing it soon begins to ferment, and becomes red in consequence of the formation of acetic acid. Evaporated to dryness, with the addition of lime or an alkali, it forms the colour called by painters *sap-green*. The dried fruit of another species, *R. infectorius*, yields a rich yellow colour, for which it is employed in the arts under the name of *French berries*.

Vogel obtained from the juice of the berries a peculiar colouring matter, acetic acid, mucilage, sugar, and a nitrogenous substance. Hubert found green colouring matter, acetic and malic acids, brown gummy matter, and a bitter substance which he considered as the purgative principle. M. Fleury obtained a peculiar crystallizable principle, which is contained both in the expressed juice and the residue remaining after expression, and for which he proposed the name of *rhamnin;* but he did not ascertain whether it possessed cathartic properties. (See *Journ. de Pharm.*, xxvii. 666.) Winckler obtained from the ripe fruit a principle which he called *cathartin*, and believes that the rhamnin of Fleury, which was obtained from the unripe berries, is converted into that principle and grape sugar as the fruit matures. (*Chem. Gaz.*, viii. 232.) The *cathartin* of Winckler, which must not be confounded with the substance of the same name at one time supposed to be the purgative principle of senna, may be procured by evaporating the expressed juice of the berries to the consistence of syrup, treating this repeatedly with boiling absolute alcohol till it ceases to yield bitterness to the menstruum, mixing the tinctures, allowing the liquor to become cold, filtering, adding a large excess of ether, allowing the mixed liquids to stand, then filtering, evaporating in a water-bath, and repeating the process with the residue. The cathartin thus obtained is a pale-yellow powder, very bitter, soluble in water and alcohol but not in ether, and actively cathartic in the dose of from one to three grains. (See *N. Y. Journ. of Pharm.*, April, 1853, and *Am. Journ. of Pharm.*, xxv. 526.)

Medical Properties and Uses. Both the berries and the expressed juice are actively purgative; but, as they are apt to occasion nausea and severe griping, with much thirst and dryness of the mouth and throat, they are now little employed. They formerly enjoyed considerable reputation as a hydragogue cathartic in dropsy; and were given also in rheumatism and gout. The only shape in which they are now used is that of syrup, which is sometimes added to hydragogue or diuretic mixtures. A syrup is directed in the Br. Pharmacopœia. The dose of the recent berries is about a scruple, of the dried a drachm, of the expressed juice a fluidounce, and of the syrup from four to eight fluidrachms. Under the name of *cortex frangulæ*, the bark of *Rhamnus Frangula* is used in Germany as a cathartic. Buchner found in this bark a peculiar yellow volatile colouring principle, which he called *rhamnoxanthin*, and which may be obtained by subjecting the alcoholic and ethereal extract to distillation. (*Journ. de Pharm.*, 3e sér., xxiv. 293.)

RHEUM. *U. S.*

Rhubarb.

The root of Rheum palmatum, and of other species of Rheum. *U. S.*

Off. Syn. RHEI RADIX. *Rhubarb Root.* The dried root, deprived of the bark, from one or more undetermined species of Rheum, from China, Chinese Tartary, and Thibet. Imported from Shanghai and Canton, and brought overland by way of Moscow. *Br.*

Rhabarbarum; Rhubarbe, *Fr.;* Rhabarber, *Germ.;* Rabarbaro, *Ital.;* Ruibarbo, *Span.;* Hai-noung, *Chinese;* Schara-modo, *Thibet.*

RHEUM. *Sex. Syst.* Enneandria Trigynia. — *Nat. Ord.* Polygonaceæ.

Gen. Ch. Calyx petaloid, six-parted, withering. *Stamens* about nine, inserted into the base of the calyx. *Styles* three, reflexed. *Stigmas* peltate, entire. *Achenium* three-cornered, winged, with the withered calyx at the base. *Embryo* in the centre of the albumen. (*Lindley*)

Notwithstanding the length of time that rhubarb has been in use, it has not yet been determined from what precise plant the Asiatic drug is derived. The remoteness of the region where it is collected, and the jealous care with which the monopoly of the trade is guarded, have prevented any accurate information on the subject. All that we certainly know is that it is the root of one or more species of Rheum. The U. S. Pharmacopœia refers it to *R. palmatum*, with other species not designated; the British recognises no particular species.

The terms *rha* and *rheon*, from the former of which were derived the names *rhabarbarum* and *rhubarb*, and from the latter the botanical title *Rheum*, were applied by the ancients to a root which came from beyond the Bosphorus, and which is supposed, though upon somewhat uncertain grounds, to have been the product of the *Rheum Rhaponticum*, growing on the banks of the Caspian Sea and the Wolga. This species was also at one time believed to be the source of the medicine now in use; but the true rhubarb has long been known to be wholly distinct from the Rhapontic, and derived from a different source. It was not till the year 1732 that any probable information was obtained as to its real origin. At that time plants were received from Russia by Jussieu in France, and Rand in England, which were said to be of the species affording the genuine rhubarb, and were named by Linnæus, under this impression, *Rheum Rhabarbarum*, a title which has since given way to *Rheum undulatum*. Subsequently, Kauw Boerhaave obtained from a merchant, who dealt in the rhubarb of Tartary, some seeds which he said were those of the plant producing the root sold by him. These, having been planted, yielded two species of Rheum, *R. undulatum*, and another which Linnæus named *R. palmatum*. Seeds transmitted by Dr. Mounsey from St. Petersburg to Dr. Hope, and planted in the botanic garden at Edinburgh, produced the latter species; and the same was also raised at Upsal from a root received by Linnæus from De Gorter, and was described A. D. 1767 by the younger Linnæus, two years after the appearance of Dr. Hope's paper in the Philosophical Transactions. Thus far the evidence appears equally in favour of *R. palmatum* and *R. undulatum*. The claims of another species were afterwards presented. Pallas, upon exhibiting the leaves of *R. palmatum* to some Bucharian merchants, was told that the leaves of the rhubarb plant were entirely different in shape; and the description he received of them corresponded more closely with those of *R. compactum*, than of any other known species. Seeds of this plant were, moreover, sent to Miller from St. Petersburg, as those of the true Tartarian rhubarb. A few years since the attention of naturalists was called to a fourth species, for which the same honour has been claimed. Dr. Wallich, superintendent of the botanical garden at Calcutta, received seeds that were said to be those of the plant which yielded the Chinese rhubarb, growing on the Himalaya mountains and the highlands of Tartary. These produced a species not previously described, which Dr. Wallich named *R. Emodi*, from the native title of the plant. It is the *R. australe* of Mr. Don and of Colebrooke, and has been

ascertained to afford a root which, though purgative, is very unlike the officinal rhubarb. Other species have been found to grow in the Himalaya mountains, from which a kind of rhubarb used by the natives is said to be procured; but none of it reaches the markets of this country or Europe. From what has been said, it is obvious that no species yet mentioned can be considered as the undoubted source of commercial rhubarb; the plant having, in no instance, been seen and examined by naturalists in its native place. Sievers, an apothecary sent to Siberia, in the reign of Catharine II., with the view of improving the cultivation of the native rhubarb, asserts, from information given him by the Bucharians, that all the seeds procured under the name of true rhubarb are false, and pronounces "all the descriptions in the Materia Medicas to be incorrect." This assertion, however, has no relation to *R. australe* which has been subsequently described; but it is said that the roots of that plant, dried by the medical officers of the British army, differ from true rhubarb in appearance and power.

All the plants of this genus are perennial and herbaceous, with large branching roots, which send forth vigorous stems from four to eight feet or more in height, surrounded at their base with numerous very large petiolate leaves, and terminating in lengthened branching panicles, composed of small and very numerous flowers, resembling those of the Rumex or dock. There is some difficulty in arranging the species, in consequence of the tendency of the cultivated plants to form hybrids; and it is frequently impossible to ascertain to which of the wild types the several garden varieties are to be referred. The following descriptions are from the *Flora Medica* of Dr. Lindley.

Rheum palmatum. Willd. *Sp. Plant.* ii. 489; Lindley, *Flor. Med.* p 358; Carson, *Illust. of Med. Bot.* ii. 22, pl. 69. "Leaves roundish-cordate, half palmate; the lobes pinnatifid, acuminate, deep dull-green, not wavy, but uneven and very much wrinkled on the upper side, hardly scabrous at the edge, minutely downy on the under side; sinus completely closed; the lobes of the leaf standing forwards beyond it. Petiole pale-green, marked with short purple lines, terete, obscurely channeled quite at the upper end. Flowering stems taller than those of any other species." This species is said to inhabit China in the vicinity of the great wall. It has been cultivated in England and France for its root, which is admitted to approach more nearly in odour, taste, and the disposition of its colours, than that of any other known species, to the Asiatic rhubarb.

R. undulatum. Willd. *Sp. Plant.* ii. 489; Lindley, *Flor. Med.* p. 357; Woodv. *Med. Bot.*, 3d ed., v. 81. "Leaves oval, obtuse, extremely wavy, deep-green, with veins purple at the base, often shorter than the petiole, distinctly and copiously downy on each side, looking as if frosted when young, scabrous at the edge; sinus open, wedge-shaped, with the lower lobes of the leaves turned upwards. Petiole downy, blood-red, semi-cylindrical, with elevated edges to the upper side, which is narrower at the upper than the lower end." This is a native of Siberia, and probably Tartary and China. It was cultivated by the Russian government as the true rhubarb plant; but the culture has been abandoned. It contributes to the rhubarb produced in France.

R. compactum. Willd. *Sp. Plant.* ii. 489; Lindley, *Flor. Med.* p. 358; Carson, *Illust. of Med. Bot.* ii. 24, pl. 71. "Leaves heart-shaped, obtuse, very wavy, deep-green, of a thick texture, scabrous at the margin, quite smooth on both sides, glossy and even on the upper side; sinus nearly closed by the parenchyma. Petiole green, hardly tinged with red except at the base, semi-cylindrical, a little compressed at the sides, with the upper side broad, flat, bordered by elevated edges, and of equal breadth at each end." This plant is said to be a native of Tartary and China. It is one of the garden rhubarbs, and has been cultivated in France for its root.

R. australe. Don, *Prod. Flor. Nepal.* p. 75. — *R. Emodi.* Wallich; Lindley, *Flor. Med.* p. 354; Carson, *Illust. of Med. Bot.* ii. 24, pl. 70. "Leaves cordate, acute, dull-green, but little wavy, flattish, very much wrinkled, distinctly rough, with coarse short hairs on each side; sinus of the base distinctly open, not wedge-shaped but diverging at an obtuse angle, with the lobes nearly turned

upwards. Petioles very rough, rounded-angular, furrowed; with the upper side depressed, bordered by an elevated edge, and very much narrower at the upper than the lower end." The root of this species was at one time conjectured to be the source of officinal Asiatic rhubarb, but has been found to have scarcely any resemblance to it. The plant has been cultivated both in Europe and this country, and its petioles answer well for tarts, &c.

R. Rhaponticum. Willd. *Sp. Plant.* ii. 488; Lindley, *Flor. Med.* p. 357; Loudon's *Encyc. of Plants*, p. 335. "Leaves roundish-ovate, cordate, obtuse, pale-green, but little wavy, very concave, even, very slightly downy on the under side, especially near the edge, and on the edge itself; scabrous at the margin; sinus quite open, large, and cuneate. Petiole depressed, channeled on the upper side, with the edges regularly rounded off, pale-green, striated, scarcely scabrous. Panicles very compact and short, always rounded at the ends, and never lax as in the other garden species. Flowering stem about three feet high." The Rhapontic rhubarb grows upon the banks of the Caspian Sea, in the deserts between the Wolga and the Oural, and in Siberia. It is said also to grow upon the borders of the Euxine. It is cultivated as a garden plant in Europe and this country; and large quantities of the root are produced for sale in France. It is said by Royle to be the source of the English rhubarb.

Besides the above species, *R. leucorrhizum*, growing in the Kirghese desert in Tartary, *R. Caspicum* from the Altaï mountains, *R. Webbianum*, *R. speciforme*, and *R. Moorcraftianum*, natives of the Himalaya mountains, and *R. crassinervium* and *R. hybridum*, cultivated in Europe, but of unknown origin, yield roots which have either been employed as purgatives, or possess properties more or less analogous to those of officinal rhubarb, though they have not entered into general commerce.

The leafstalks of the different species of Rheum have a pleasant acid taste, and are used for making tarts and pies. It is for this purpose mainly that the plants are cultivated in the United States. Mr. T. A. Lancaster has shown that the acidity is owing to the presence of binoxalate of potassa. (*Am. Journ. of Pharm.*, May, 1859, p. 193.) Lindley states that R. Rhaponticum, R. hybridum, and R. compactum, and hybrid varieties of them, are the common garden rhubarbs.*

In relation to the culture and preparation of rhubarb, our information is almost as uncertain as on the subject of its natural history. The accounts received from the Bucharian merchants are very discordant, and few intelligent travellers have penetrated into the country where the medicine is collected. We shall present, however, a brief abstract of what we have been able to collect upon the subject from the authorities we have consulted.

Rhubarb is produced abundantly in the elevated lands of Tartary, about the lake Koko Norr, and is said to be cultivated in the neighbouring Chinese province of Shen-see, and in that of Setchuen. From these sources it is generally supposed that our supplies of Russian and Chinese rhubarb are exclusively derived; but the root is also collected in Boutan and Thibet, on the north of the Himalaya mountains; and it is probable that the plant pervades the whole of Chinese Tartary. It flourishes best in a light sandy soil. It is stated by Mr. Bell, who, on a journey from St. Petersburg to Pekin, had an opportunity of observing it in a growing state, that it is not cultivated by the Tartars, but springs up spontaneously, in tufts, wherever the seeds have fallen upon the heaps of loose earth thrown up by the marmots. In other places the thickness of the

* *Wine from the Rhubarb Plant.* Large quantities of wine are said to be prepared, at Belvidere, Illinois, from the garden rhubarb. The plant, having been cut when mature, is submitted to pressure; and the expressed juice, with an equal bulk of water and seven pounds of sugar for each gallon, is made to undergo the vinous fermentation. The wine is fit for use at the end of three years. It has a pleasant sweetish taste, said to resemble that of imported sherry; and an alcoholic strength varying from 7 to 10 per cent. The possession of an aperient property is, perhaps, its strongest recommendation. Ten thousand gallons are stated as the product of a single season. (*Am. Journ. of Pharm.*, Jan. 1866.)—*Note to the thirteenth edition.*

grass prevents their access to the soil. The root is not considered sufficiently mature for collection till it has attained the age of six years. It is dug up twice a year in Tartary, in the spring and autumn; in China not till the winter. After removal from the ground, it is cleaned, deprived of its cortical portion and the smaller branches, and then divided into pieces of a convenient size. These are bored with holes, and strung upon cords to dry; according to Mr. Bell, about the tents and on the horns of sheep; according to Sievers, under sheds, by which the rays of the sun are excluded, while the air has free access. The Chinese are said first to place the pieces on a stone slab heated by fire beneath, and afterwards to complete the drying process by exposing them to the sun and air. In Boutan the roots are hung up in a kind of drying room, in which a moderate and regular heat is maintained. Much time and attention are devoted to the preparation of the root; and Sievers states that a year sometimes elapses from the period of its collection, before it is ready for exportation. A large proportion of its weight is lost in drying, according to some accounts four-fifths, to others not less than seven-eighths. It is probably in order to favour the drying that the bark is removed. The trade in rhubarb is said to centre in the Chinese town of Si-nin, where a Bucharian company or family is established, which possesses a monopoly of this trade, in consideration of a certain tribute paid to the government. To this city the rhubarb is brought from the various places of its collection, and, having been duly assorted and undergone further preparation, is transmitted partly to Russia, partly to the coast of China; so that the drug which reaches us through St. Petersburg is procured from the same neighbourhood with that imported from Canton. But it will soon be seen that there are differences between the Russian and Chinese rhubarb, which would seem to indicate a different origin, and might authorize doubts as to the entire accuracy of the above accounts. It is at least probable that the drug produced in the province of Setchuen, whence the best China rhubarb is said to be brought, takes a more direct route to the coast than that through the town of Si-nin. Besides the two commercial varieties just mentioned, a third occasionally comes to us from Europe, where the cultivation of rhubarb has been carried on for some time, especially in France, Belgium, and Great Britain. Of these three varieties we shall treat under different heads.

1. *Chinese Rhubarb.*

India Rhubarb. Rheum Sinense vel *Indicum.* Much the largest proportion of rhubarb consumed in this country is brought from Canton. Though somewhat inferior to the Russian, its comparative cheapness gives it a decided preference in our markets; and, when of good quality, it does not disappoint the expectations of the physician.

It is in cylindrical or roundish pieces, sometimes flattened on one or both sides, of a dirty brownish-yellow colour externally, appearing as if the cortical portion of the root had been removed by scraping, and the surface rendered smooth and somewhat powdery by attrition. The best pieces are heavier than the Russian rhubarb, have a texture rather close and compact, and, when broken, present a ragged uneven surface, variegated with intermingled shades of dull-red, yellowish, and white, which are sometimes diversified or interrupted by darker colours. The pieces are generally perforated with small holes, intended for convenience of suspension during the drying process; and portions of the suspending cord are not unfrequently found remaining in the holes. Chinese rhubarb has a peculiar somewhat aromatic smell, and a bitter astringent taste, is gritty when chewed, imparts a yellow colour to the saliva, and affords a yellowish powder with a reddish-brown tinge. With the pieces of good quality others often come mingled, defective from decay or improper preparation. These are usually lighter, and of a dark or russet colour. Like all the other varieties of rhubarb, this is liable to be attacked by worms; and in almost every large parcel pieces may be found which have suffered from this cause. The want of

proper care in its selection by the Chinese merchants, and the exposure incident to a long sea-voyage, are causes which contribute to its inferiority to the Russian rhubarb. As the whole contents of the chest imported are usually powdered together, including the worst as well as the best pieces, it follows that the powder is inferior in efficacy to the selected and sound pieces. We are told by English pharmaceutists that, owing to a wide-spread destruction by the rebels, or some unknown cause, of the rhubarb plant in its native country, both the quantity and quality of Chinese rhubarb have been recently lowered in the market; but that the plant was recovering itself in China, and consequently that the root is now improving in both these respects. (*Pharm. Journ. and Trans.*, Oct. 1868, p. 247.)

In former editions of this work, we have noticed a variety of rhubarb imported from Canton, which was evidently prepared, before leaving China, so as to resemble the Russian, having an angular surface as if pared with a knife. The pieces were obviously selected with great care, as they were remarkably free from defects. But in most of those which came under our notice, the small penetrating hole was observable, which characterizes the Chinese rhubarb, though it had in some instances been filled with the powdered root, so as in some measure to conceal it. Besides, the colours were not quite so bright as those of Russia rhubarb. This is undoubtedly the variety described by Pereira, under a distinct head, as the *Dutch-trimmed* or *Batavian rhubarb*, and considered by him as probably Bucharian or Russian rhubarb of inferior quality, sent by the way of Canton. A sufficient proof, we think, that this is not the case, is the presence in most pieces of the small penetrating hole, occasionally filled with remains of the cord, and in some pieces almost shaved away in the paring process. We have never seen such a hole in any piece of true Russian rhubarb, which does not appear to be strung up like the Chinese when dried.

Under the title of *Canton stick rhubarb*, Pereira describes a variety of which small quantities have been imported from Canton into London. It closely resembles the English stick rhubarb, and is supposed to be derived from the branches of the root of the plant which yields the true Chinese rhubarb.

2. *Russian Rhubarb.*

Turkey Rhubarb. Bucharian Rhubarb. Rheum Russicum vel *Turcicum* The rhubarb taken to Russia from Tartary undergoes a peculiar preparation, in conformity with the stipulations of a contract with the Bucharian merchants who furnish the supply. The best is selected, and each piece perforated in order to ascertain whether it is sound in the centre. From Si-nin it is conveyed by the Bucharian merchants to the frontier town of Kiachta, where it undergoes a rigid inspection by an apothecary stationed at that place by the Russian government. All the pieces which do not pass examination are committed to the flames; and the remainder is sent to St. Petersburg. This variety is sometimes called *Turkey rhubarb*, from the circumstance that it was formerly derived from the Turkish ports, whither it is said to have been brought from Tartary by caravans through Persia and Natolia. The circumstance of the identity of the Russian and Turkey rhubarb, and its decided difference from the Chinese, would appear to indicate a distinct origin for the two varieties. Inferior parcels of the root, which will not pass the inspection of the Russian authorities, are said to enter Russia by Taschkent, and to be known to the druggists of that country by the name of *Taschkent rhubarb.*

The pieces of Russian rhubarb are irregular and somewhat angular, appearing as if the bark had been shaved off longitudinally by successive strokes of a knife, and a portion of the interior substance removed with each shaving. They have a cleaner and fresher appearance than the Chinese, and their colour both internally and externally, though of the same general character, is somewhat more lively. They are less compact and heavy; and are cut with less facility, owing to their giving way before the knife. Another distinction is the character

of the perforations, which in the Russian rhubarb are large, frequently reaching only to the centre, and evidently made for the purpose of inspection; while in the Chinese they are small, penetrate completely through the pieces, and were intended for the passage of a suspending cord. The taste and smell of the former closely resemble those of the latter, except that the Russian is rather more aromatic. There is the same crackling under the teeth, and the same yellow stain imparted to the saliva; but the colour of the powder in this variety is a bright yellow, without the brownish tinge exhibited by the Chinese. When thin slices, previously boiled in water, are examined by the microscope, they exhibit numerous clusters of minute crystals of oxalate of lime. Mr. Quekett found between 35 and 40 grains of them in 100 grains of the root. They are observed both in the Russian and Chinese rhubarb.

The care which renders the Russian rhubarb so free from defects, tends greatly to enhance its price, and consequently to limit its consumption. Its great comparative value in the market has led to frequent attempts at adulteration; and the pieces of Chinese rhubarb are sometimes cut down and prepared so as to resemble the Russian. The fraud, however, may be detected by adverting to the peculiarities in texture, colour, and weight, by which the varieties are distinguished, and to the occasional presence of the small penetrating hole, or vestiges of it. We have seen a specimen in which the hole was enlarged at its two extremities, and closed by powder in the middle, with the view of imitating the larger perforations of the Russian pieces. Sometimes worm-eaten pieces are made to resemble the sound, by filling up the holes with a mixture of pulverized rhubarb and mucilage, and covering over the surface with the powder. By removing this, the fraud is at once revealed.

Within a few years genuine Russia rhubarb has been gradually diminishing, and at this time (Jan. 1869) has wholly disappeared from the market, both European and American. This is owing to the suspension of the inspection established by the Russian government at Kiachta, through which a certain excellence of character, and certain peculiarities of form, were given to that variety of rhubarb which distinguished it from all others. It is to be hoped that similar regulations may be again established, causing a return of the genuine Russia rhubarb to our markets. In the mean time, as the cultivation probably goes on as before, we shall receive really the same rhubarb through other channels, but somewhat different in form, and mixed with much that is inferior.*

* In the *American Journal of Pharmacy* (May, 1867, p. 212) is a paper by Adolph Fero, of Moscow, translated by Prof. Maisch from the *Pharmaceut. Zeitschrift für Russland* (Nov. 1866, pp. 473–481), which gives an account of the rhubarbs at present in Russian commerce, and to which the reader is referred for interesting observations on this subject. We have space only for a very brief notice of the several varieties.

1. *North-Chinese Rhubarb.* By this name the author distinguishes the rhubarb now entering Russia by various routes along the northern Chinese frontier, and especially through Siberia to the fair at Nishni-Novogorod, where it comes in chests containing 200 lbs. The pieces weigh from one to seven ounces, are mostly uncut or only split longitudinally, resemble the Russian in shape and colour, are entirely or partially destitute of the cortical part, and are usually perforated with holes for suspension, but rarely with those made for inspection, and with these only in imitation of the Russian. Their mean length is 2¾ inches, breadth 1¾. Their texture is somewhat loose, frequently porous.

2. *Bucharian Rhubarb.* This is taken from Bucharia to Russia, being first carried to the Caspian Sea, and then up the Wolga to Nishni-Novogorod, whence it is distributed. The pieces of this variety are marked with the perforating holes for suspension, and sometimes with others in imitation of the Russian, intended for inspection. There are two kinds, one deprived of the cortical portion, the other in the natural state in this respect. In the former the surface is smooth, the outer part seeming to have been carefully removed by a file; the latter has longitudinal wrinkles. Generally, the dimensions exceed those of the former variety, being on the average 3½ inches long, 2½ wide, and 1¼ thick; the root being divided longitudinally into two halves, with the cut surface somewhat curved by contraction. The surface of the pieces is usually purposely sprinkled with the powder. In compactness this resembles the Chinese rhubarb; and its texture is more woody and fibrous than in any other variety.

The proper Russian rhubarb is also described under the name of the *Muscovite*, and the Chinese rhubarb, as we denominate it, under that of *South Chinese;* but in reference to these there is nothing that especially requires attention. (*Note to the thirteenth edition.*)

3. *European Rhubarb.*

In various parts of Europe, particularly in England, France, Belgium, and Germany, the rhubarb plants have been cultivated for many years; and considerable quantities of the root are annually brought into the market. It is imported into this country from England and France.

English Rhubarb. This formerly came in two forms. In one the root was cut and perforated in imitation of the Russian. The pieces were of various shape and size, sometimes cylindrical, but more commonly flat, or somewhat lenticular, and of considerable dimensions. We have for a long time seen none of this variety in our markets. In the other, the pieces are somewhat cylindrical, five or six inches long by an inch or less in thickness, and more or less irregular upon the surface, as if they had shrunk unequally in drying. This is called *stick rhubarb* in England, and until very recently was occasionally met with in our shops. English rhubarb is lighter than the Asiatic, more spongy, and often somewhat pasty under the pestle. It is redder, and when broken exhibits a more compact and regular marbling; the pinkish lines being arranged like rays from the centre towards the circumference. The powder also has a deeper reddish tint. The odour is feeble and less aromatic than that of the Asiatic varieties; the taste is astringent and mucilaginous with little bitterness; and the root, when chewed, scarcely feels gritty between the teeth, and but slightly colours the saliva. Few crystals of oxalate of lime are discoverable by means of the microscope. Most of the commercial English rhubarb is now cultivated near Banbury, and is said to be the product of R. Rhaponticum.

The cultivation of rhubarb in England has within a few years taken a new start, and the demand for the root has greatly increased both at home and abroad; so that at present it even exceeds the production. Mr. Rufus Usher, who is engaged in this culture at Banbury, and whose plantations of rhubarb exceed forty acres in extent, ascribes the increased demand to the improved quality of the product, which he believes to have arisen from the propagation by offsets instead of by seeds; the roots, in the former method, having a tendency to return to the original type; while, through the seeds, new varieties are formed in which the old characters are lost. (*Am. Journ. of Pharm.*, Nov. 1867, p. 481; from *Pharm. Journ.*, Aug. 1867.) But, notwithstanding this increased demand for English rhubarb, little if any is imported into the U. States; and the result of an investigation which has been made into the subject at our request is that, in two of our largest drug centres, none of this variety is to be found in the market.

French Rhubarb. Rhapontic Rhubarb. Krimea Rhubarb. The rhubarb produced in France is, according to Guibourt, chiefly from *R. Rhaponticum*, *R. undulatum*, and *R. compactum;* that of *R. palmatum*, which most closely resembles the Asiatic, having been found to degenerate so much as not to be a profitable object of culture. Most of the French rhubarb is produced in the neighbourhood of L'Orient, in the department of Morbihan; and the spot where it grows has, from this circumstance, received the name of *Rheumpole.* Two kinds are described by Guibourt, both under the name *Rhapontic root.* One proceeds from the R. Rhaponticum, growing in the gardens in the environs of Paris; the other, from this and the two other species above mentioned, cultivated at Rheumpole. The former is in pieces of the size of the fist or smaller, ligneous in appearance, of a reddish-gray colour on the outside, internally marbled with red and white arranged in the form of crowded rays proceeding from the centre to the circumference, of an odour like that of Asiatic rhubarb, but more disagreeable, of a mucilaginous and very astringent taste, not crackling under the teeth, but tinging the saliva yellow, and affording a reddish-yellow powder. The pieces of the latter are irregularly cylindrical, three or four inches long, and from one to two or even three inches thick, less ligneous in appearance than the preceding, and externally of a pale or brownish-yellow colour less inclining to redness. In exterior aspect, this variety bears considerable

resemblance to Chinese rhubarb; but may be distinguished by its more disagreeable odour, its astringent and mucilaginous taste, its want of crackling under the teeth, and its radiating fracture, in which properties it is similar to the preceding variety. Considerable quantities of this drug have been imported into the United States from France, under the name of *Krimea rhubarb;* and it has been employed to adulterate the powder of the better kinds.* It appears to have displaced in France the *Rhapontic root* formerly imported from the Euxine. Whether from difference in species, or from the influence of soil and climate, none of the European rhubarbs equals the Asiatic in purgative power.†

Choice of Rhubarb. In selecting good rhubarb, without reference to the commercial variety, those pieces should be preferred which are moderately heavy and compact, of a lively colour, brittle, presenting when broken a fresh appearance, with reddish and yellowish veins intermingled with white, of an odour decidedly aromatic, of a bitter and astringent not mucilaginous taste, feeling gritty and staining the saliva yellow when chewed, and affording a powder either bright yellow, or yellow with but a slight reddish-brown tinge. When very light, rhubarb is usually rotten or worm-eaten; when very heavy and compact, it is of inferior species, culture, or preparation. Rotten, worm-eaten, or otherwise inferior rhubarb is often powdered, and coloured yellow with turmeric; and the shavings left when Chinese rhubarb is trimmed for powdering, or to imitate the Russian, are applied to the same purpose.

Chemical Properties. Rhubarb yields all its activity to water and alcohol. The infusion is of a dark reddish-yellow colour, with the taste and odour of rhubarb; and the residue, after sufficient maceration, is whitish, inodorous, and insipid. By long boiling, the virtues of the medicine are impaired. Many attempts have been made to analyze the root, with various results. Among them, are those of the two Henrys and Caventou of Paris, Brande of London, Peretti of Rome, and Hornemann, Brandes, and Schlossberger and Döpping of Germany. Brandes found, in 100 parts of Chinese rhubarb, 2 of pure *rhabarbaric acid*, 7·5 of the same acid impure, 2·5 of gallic acid, 9·0 of tannin, 3·5 of colouring extractive, 11·0 of uncrystallizable sugar with tannin, 4·0 of starch, 14·4 of gummy extractive, 4·0 of pectic acid, 1·1 of malate and gallate of lime, 11·0 of oxalate of lime, 1·5 of sulphate of potassa and chloride of potassium, 1·0 of silica, 0·5 of phosphate of lime and oxide of iron, 25·0 of lignin, and 2·0 of water. The most recent elaborate analysis which has come to our notice is that of Schlossberger and Döpping. Besides extractive, tannic and gallic acids, sugar, starch,

* M. E. Billot gives the following method of detecting the rhapontic root, when used in powder to adulterate Russian or Chinese rhubarb. On a little of the suspected powder, upon a plate, let fall two or three drops of oil of anise, oil of fennel, or other essential oil; then add magnesia, and rub the mixture well for three or four minutes. If the powder be pure, it will remain yellow; but if it contain the smallest quantity of the French rhapontic root, it will assume a reddish tint, varying from a salmon to a bright rose-colour, according to the quantity of the impurity present. (See *Am. Journ. of Pharm.*, May, 1860, p. 224.)

† Besides the varieties of rhubarb above described, others are noticed by writers. Pallas speaks of a *white rhubarb*, brought to Kiachta by the Bucharian merchants, who conveyed to that place the drug for Russian commerce. It was white as milk, of a sweet taste, and equal to the best rhubarb in quality. It was supposed to be the product of *R. leucorrhizum*. At present, however, it is unknown in St. Petersburg. The *Himalaya rhubarb* is produced by R. australe, and other species mentioned in the text as growing in the Himalaya mountains. According to Dr. Royle, it makes its way to the lower countries in Hindostan, where it sells for one-tenth of the price of the best rhubarb. Mr. Twining tried it in the Hospital at Calcutta, and found it superior as a tonic and astringent to Russian rhubarb, and nearly equal to it in purgative power. A variety known in Russia as *Bucharian rhubarb*, differing from the variety which we call Russian, and which is known in Russia as Chinese rhubarb, is imported into that country from Tartary, and reaches St. Petersburg by Nishni. Parcels of it are said also to reach Vienna, by the way of Brody in Gallicia. Still another variety is that called *Siberian rhubarb*, which is known in Russia by the name *Siberian Rhapontic root*. As these are inferior kinds, and probably never reach our markets, we have not thought it necessary to swell our pages with descriptions of them. The reader who wishes further information is referred to papers by Pereira, in the *London Pharmaceutical Journal*, republished in the *Am. Journ. of Pharm.* (xviii. 63 and 123).

pectin, lignin, oxalate of lime, and various inorganic salts, they discovered three colouring principles, holding an intermediate place between resin and extractive matter, being freely soluble in alcohol, and slightly so in water. Two of these were uncrystallizable, and denominated *brown resin* and *red resin*, or *phæoretin* and *erythroretin;* the other, crystallizable in granular crystals, and identical with the *chrysophanic acid*, previously discovered by Rochleder and Heldt in the yellow lichen, or Parmelia parietina of Sprengel. Another resinous substance was also obtained, which was named *aporetin;* but, as it was insoluble in the alcohol from which it had been precipitated by ether, and was isomeric with phæoretin, there is reason to think that it was a product of the operation. The three principles above referred to were obtained by exhausting rhubarb with alcohol, evaporating the tincture, exhausting the extract with water, dissolving the residue in the least possible quantity of alcohol, and treating this solution with ether. A precipitate was produced, a portion of which (aporetin) was insoluble in alcohol, and the remainder was obtained separate by solution in that fluid and evaporation. This was *phæoretin*. It is a yellowish-brown powder, very slightly soluble in water and ether, freely soluble in alcohol and in alkaline solutions, with which it produces an intense reddish-brown colour, and from which it is thrown down yellow by the mineral acids. The ethereal solution of the alcoholic extract, after all the aporetin and phæoretin had been separated, was allowed to evaporate spontaneously, and a large quantity of crystalline granules was obtained, of a beautiful yellow colour. These being washed with ether constituted the *chrysophanic acid*. When the ethereal solution showed no longer a disposition to deposit crystals, it was evaporated, and yielded a product having all the properties of the resins, and forming beautiful purple combinations with potassa and ammonia. This was the *erythroretin*, or red resin of rhubarb. The matter dissolved by water from the alcoholic extract was found to have the odour and taste of rhubarb in a high degree. In this, no doubt, was contained the peculiar active principle or principles of rhubarb; but Schlossberger and Döpping were not more successful than their predecessors in isolating them. They obtained a slightly bitter extractive matter; but it wanted the flavour of rhubarb. (*Pharm. Journ.*, iv. 136, 232, 318, and viii. 190.)

Many distinguished chemists have sought for the purgative ingredient of rhubarb, and some not without supposed success; but scarcely has the new principle been described and named, before the fallacy of its claim has been determined. The *caphopicrite* of Henry, the *rhabarbarin* of Pfaff and others, the *rheumin* of Hornemann, the *rhabarbaric acid* of Brandes, and, lastly, the *rhein* of Professor Dulk, have all been shown to be bodies more or less complex; and certainly no one of them can be admitted to be the peculiar purgative principle. The astringency of rhubarb undoubtedly resides in its tannic acid. Some have supposed that the tonic and cathartic properties reside in different principles; but we are disposed to think, from the correspondence of the bitterness with the purgative property, that they reside in the same substance; and, from the fact that exposure to heat diminishes the cathartic power, there is reason to believe that this substance, when isolated, will prove to be more or less volatile.

Chrysophanic acid (*chrysophane*) is one of the most interesting constituents. Most of the hitherto supposed active principles have been mixtures of this with other substances. The rhabarbaric acid of Brandes probably approaches nearest to it in character. When pure it is beautifully yellow, without smell or taste, disposed to an imperfect granular crystallization, almost insoluble in cold water, more soluble in hot water and in ether, but most freely and yet feebly so in alcohol. Benzole appears to be its best solvent. When heated it emits yellow vapours. Alkaline solutions dissolve it with the production of a beautiful red colour; and the solution with potassa, when evaporated, changes first to violet, and then to blue. It forms definite compounds with the alkalies, but its acid properties are very feeble, and even carbonic acid separates it from its combinations. Its formula, according to Pilz, is $C_{20}H_8O_6$. (*Journ. de Pharm.*, Mars, 1862, p. 254.) It is probably the chief ingredient in the fine yellow colouring

matter produced by the reaction of nitric acid on rhubarb, which, in consequence of the magnificent purples produced by it with the alkalies, M. Garot has proposed, under the name of *erythrose*, to introduce into the arts as a dye-stuff. (See *Journ. de Pharm.*, xvii. 5.)*

There are other interesting principles in rhubarb. Some have been disposed to ascribe its odour to a volatile oil; but this has not been isolated. Tannic acid is an important constituent. It is of that variety which precipitates the salts of sesquioxide of iron of a greenish colour. The oxalate of lime is interesting from its quantity, and from the circumstance that, existing in distinct crystals, it occasions the grittiness of the rhubarb between the teeth. The proportion seems to vary exceedingly in different specimens. According to Scheele and Henry, it constitutes nearly one-third, and Quekett found, as already stated, between 35 and 40 per cent.; while Brandes obtained only 11, and Schrader only 4·5 parts in the hundred. Little or no difference of composition has been found between the Russian and Chinese rhubarb. The European contains but a small proportion of oxalate of lime, and is therefore less gritty when chewed. It has, however, more tannin and starch than the Asiatic.

When powdered rhubarb is heated, odorous yellow fumes rise, which are probably in part the vapour of chrysophanic acid. Its infusion is reddened by the alkalies, in consequence of their union with this acid, and their reaction on the other colouring principles. It yields precipitates with gelatin, most of the acids, the salts of sesquioxide of iron, acetate of lead, nitrate of protoxide of mercury, nitrate of silver, protochloride of tin, lime-water, and solutions of quinia. Nitric acid occasions at first a turbidness, and afterwards the deposition of a yellow precipitate. The substances producing precipitates may be considered as incompatible with the infusion.

Medical Properties and Uses. The medical properties of rhubarb are peculiar and valuable. Its most remarkable singularity is the union of a cathartic with an astringent power; the latter of which, however, does not interfere with the former, as the purgative effect precedes the astringent. It is also tonic and stomachic; invigorating, in small doses, the process of digestion. It is not probable that these properties reside in a single proximate principle; and, as rhubarb owes its chief value to their combination, it is not to be expected that chemical analysis will be productive of the same practical advantages in this, as in some other medicines, the virtues of which are concentrated in one ingredient. In its purgative operation, rhubarb is moderate, producing fecal rather than watery discharges, and appearing to affect the muscular fibre more than the secretory function. It sometimes occasions griping. Its colouring principle is absorbed, and may be detected in the urine. By its long-continued use, the perspiration, especially that of the axilla, is said to become yellow, and the milk of nurses cathartic. It gives a yellow colour to the alvine discharges.

The conditions of disease to which it is applicable may be inferred from its peculiar properties. When the stomach is enfeebled, or the bowels relaxed, at the same time that a gentle cathartic is required, rhubarb, as a general rule, is preferable to all others. Hence its use in dyspepsia attended with constipation, in diarrhœa when purging is indicated, in the secondary stages of cholera infantum, in chronic dysentery, and in almost all typhous diseases when fecal matter has accumulated in the intestines, or the use of cathartic medicine is necessary to prevent such accumulation. When employed in cases of habitual constipation, its astringent tendency should be counteracted by combining it with soap. Magnesia is also an excellent associate in disorders of the stomach

* Messrs. W. De la Rue and H. Müller obtain chrysophanic acid by treating with benzole rhubarb previously deprived of soluble matter by water, distilling off most of the benzole from the solution, and allowing it to cool. The chrysophanic acid is deposited in an impure state. By treating this with hot benzole, an insoluble matter is left, and more of the same is deposited when the solution cools. By filtering this is separated, and the acid is obtained from the clear liquor by concentration and crystallization. The undissolved matter is a new principle, which the authors propose to name *emodin*. (*Pharm. Journ.*, xvii 576.)—*Note to the twelfth edition.*

and bowels. By combination with other cathartics, rhubarb frequently acquires additional activity, while it gives increased efficiency to the associated substance. A mixture of calomel and rhubarb is a brisk and powerful cathartic, often used at the commencement of bilious fevers. As a general rule, rhubarb is not applicable to cases attended with much inflammatory action. Its griping effect may be counteracted by combining it with aromatics.

The dose of rhubarb as a purgative is from twenty to thirty grains, as a laxative and stomachic from five to ten grains. European rhubarb must be given in double or treble the dose to produce an equal effect. Few medicines are used in a greater variety of forms. It is most effectual in substance. It is frequently given in the shape of pill, combined with an equal proportion of soap, when its laxative effect is desired. The infusion is much used in cases of delicate stomach, and is peculiarly adapted to children. The syrup, tincture, and fluid extract are also useful preparations. They are all officinal.

By the roasting of rhubarb its cathartic property is diminished, probably by the volatilization of the purgative principle, while its astringency remains unaffected. This mode of treatment has, therefore, been sometimes resorted to in cases of diarrhœa. By long boiling the same effect is said to be produced.

Powdered rhubarb has been usefully applied to indolent and sloughing ulcers. It is said to have proved purgative when sprinkled over a large ulcerated surface; and the same effect is asserted to have been produced by rubbing it, mingled with saliva, over the abdomen.

RHŒADOS PETALA. *Br.*

Red-Poppy Petals.

The fresh petals of Papaver Rhœas. *Br.*

Coquelicot, *Fr.;* Wilder Mohn, Klapperrose, *Germ.;* Rosolaccio, *Ital.;* Amapola, *Span.*

PAPAVER. See OPIUM.

Papaver Rhœas. Willd. *Sp. Plant.* ii. 1146; Woodv. *Med Bot.* p. 387, t. 139. The *red* or *corn poppy* is distinguished by its hairy stem, which is branched and rises about a foot in height, by its incised pinnatifid leaves, by its urn-shaped capsule, and by the full, bright, scarlet colour of its petals. It is a native of Europe, where it grows wild in great abundance, adorning especially the fields of grain with its brilliant flower. It has been naturalized in this country.

Its capsules contain the same kind of milky juice as that found in *P. somniferum*, and an extract has been prepared from them having the properties of opium; but the quantity is too small to repay the trouble of its preparation. M. Tilhoi has shown that the extract contains morphia, but in a proportion exceedingly minute compared with that in which it exists in opium. (*Journ. de Pharm.*, ii. 513.) The petals are the officinal portion. They have a narcotic smell, and a mucilaginous, slightly bitter taste. By drying, they lose their odour, and assume a violet-red colour. Chevallier detected a very minute proportion of morphia in an extract obtained from them; but their operation on the system is exceedingly feeble, and they are valued more for their beautiful scarlet colour, which they communicate to water, than for their medical virtues. According to Leo Meier, the colouring principles of the flowers are two acids, which he denominates *rhœadic* and *papaveric acids.* (See *Am. Journ. of Pharm.*, xviii. 211.) A syrup is prepared from them, which was formerly prescribed as an anodyne in catarrhal affections; but is now little esteemed, except for its colour.

An alkaloid has been discovered in this species of poppy by O. Hesse, who proposes to name it *rhœadin* (*rhœadia*) It seems to pervade all parts of the plant, from which, as the first step in its preparation, a watery extract is pro-

pared. This is treated with carbonate of soda, and repeatedly agitated with ether; the ethereal liquid is shaken with a solution of bitartrate of soda; and the mixture is precipitated by ammonia. The precipitate is washed with cold water, dried, and boiled with alcohol, by which colouring matter and another alkaloid in small quantity, probably thebaina, are removed. The residue, consisting mainly of rhœadia, is purified by combining it with acetic acid, treating with animal charcoal, and precipitating with ammonia. The alkaloid is in small white prismatic crystals, tasteless, fusible at 450° F., becoming brown at the same temperature and partially subliming. It is almost insoluble in water, alcohol, ether, chloroform, benzole, ammonia, solution of carbonate of soda, and lime water; but is dissolved by dilute acids, which produce colourless solutions. Its composition is represented by the formula $C_{42}H_{21}NO_{12}$. It does not appear to be poisonous. Muriatic and sulphuric acids moderately concentrated decompose and dissolve it, with the production of a purple colour, which disappears under the action of the alkalies, but is restored by acids. One part of the alkaloid produces a purple colour with 10,000 parts of water, an intense rose colour with 20,000 parts, and a perceptible redness with 800,000 parts. This is a very delicate test, by means of which the alkaloid may be detected in all parts of Papaver Rhœas, in the ripe capsules of the opium poppy, and in opium itself. It is said also to exist in Merks' porphyroxin. (*Am. Journ. of Pharm.*, March, 1867, p. 122.)

RHUS GLABRUM. *U. S. Secondary.*

Sumach.

The fruit of Rhus glabrum. *U. S.*

Rhus. *Sex. Syst.* Pentandria Trigynia. — *Nat. Ord.* Anacardiaceæ.

Gen. Ch. Calyx five-parted. *Petals* five. *Berry* small, with one nuciform seed. *Nuttall.*

Of this genus there are several species possessing poisonous properties, which should be carefully distinguished from that here described. For an account of them the reader is referred to the article *Toxicodendron.*

Rhus glabrum. Willd. *Sp. Plant.* i. 1478. This species of Rhus, called variously *smooth sumach*, *Pennsylvania sumach*, and *upland sumach*, is an indigenous shrub from four to twelve feet or more in height, with a stem usually more or less bent, and divided into straggling branches, covered with a smooth, light-gray or somewhat reddish bark. The leaves are upon smooth petioles, and consist of many pairs of opposite leaflets, with an odd one at the extremity, all of which are lanceolate, acuminate, acutely serrate, glabrous, green on their upper surface, and whitish beneath. In the autumn their colour changes to a beautiful red. The flowers are greenish-red, and disposed in large, erect, terminal compound thyrses, which are succeeded by clusters of small crimson berries, covered with a silky down.

The shrub is found in almost all parts of the United States, growing in old neglected fields, along fences, and on the borders of woods. The flowers appear in July, and the fruit ripens in the early part of autumn. The bark and leaves are astringent, and are used in tanning leather and in dyeing. Mr. W. J. Watson found, in the bark of the root, albumen, gum, starch, tannic and gallic acids, caoutchouc, resin, colouring matter, and evidences of volatile oil. (*Am. Journ. of Pharm.*, xxv. 194.) Excrescences are produced under the leaves resembling galls in character, and containing large quantities of tannic and gallic acids. These have been used as a substitute for the imported galls by Dr. Walters, of New York, who thought them in every respect preferable. They may be collected at little expense; as they are produced very abundantly, especially in the Western States. From the experiments of Dr. Stenhouse, it appears that the tannic acid of sumach is identical with that of galls, being, like it, resolved, under

the influence of sulphuric acid, into glucose and gallic acid; and this change is supposed to take place spontaneously in sumach when long kept. (*Ibid.*, xxxiv. 252.) The only officinal part of the plant is the fruit.

The berries have a sour, astringent, not unpleasant taste, and are often eaten by the country people with impunity. According to Mr. Cozzens, of New York, the acid to which they owe their sourness is the malic, and is contained in the pubescence which covers their surface; as, when it is washed away by warm water, the berries are wholly free from acidity. Professor W. B. Rogers found the acid to be combined with lime, in the state of bimalate.* Mr. W. J. Watson ascertained that free malic acid and bimalate of lime coexist in the berries, which contain also, upon the same authority, tannic and gallic acids, fixed oil, extractive, red colouring matter, and a little volatile oil. A wine has been prepared from the fruit by adding sugar to an infusion and fermenting, which is spoken of by Dr. John H. Griscom, of New York, as a valuable remedy. (*Med. and Surg. Reporter*, Feb. 9, 1867, p. 118.)

Medical Properties and Uses. Sumach berries are astringent and refrigerant; and their infusion has been recommended as a cooling drink in febrile complaints, and a pleasant gargle in inflammation and ulceration of the throat. By Dr. Fahnestock an infusion of the inner bark of the root, employed as a gargle, is considered almost as a specific in the sore-mouth attending inordinate mercurial salivation. (*Am. Journ. of Med. Sciences*, v. 61.) W.

ROSÆ CANINÆ FRUCTUS. *Br.*

Fruit of the Dog Rose. Hips.

The ripe fruit of the Dog Rose, Rosa canina, and other indigenous allied species. *Br.*

Rose sauvage, *Fr.*; Hundsrose, *Germ.*

ROSA. See ROSA CENTIFOLIA.

Rosa canina. Willd. *Sp. Plant.* ii. 1077; Woodv. *Med. Bot.* p. 493, t. 177. The *dog rose, wild brier*, or *heptree*, is a native of Europe, and distinguished as a species by its glabrous ovate germs, smooth peduncles, prickly stem and petioles, and ovate, smooth, rigid leaves. It is eight or ten feet high, and bears white or pale-red flowers, having usually five obcordate fragrant petals. The plant has been introduced into this country, but is not much cultivated.

The fruit is fleshy, smooth, oval, red, and of a pleasant, sweet, acidulous taste; and contains sugar, and uncombined citric and malic acids.

The pulp, separated from the seeds and the silky bristles in which they are embedded, is employed in Europe for the preparation of a confection, intended chiefly as an agreeable vehicle for other medicines.

ROSA CENTIFOLIA. *U. S.*

Hundred-leaved Rose. Pale Rose. Cabbage-Rose Petals. Br.

The petals of Rosa centifolia. *U. S.*

Off. Syn. ROSÆ CENTIFOLIÆ PETALA. *Cabbage-rose Petals.* The fresh petals fully expanded of Rosa centifolia. *Br.*

* Prof. Rogers suggested that *malic acid* might be advantageously procured from this source. Prof. Procter informs us that he has obtained it by the following process. Pour boiling water on the ripe berries; macerate for twelve hours; strain, evaporate to one-fourth, and again strain; resume the evaporation and continue it till the liquid assumes the consistence of thin syrup; then set it aside to crystallize. Wash the crystals of bimalate of lime with a little water, and recrystallize from a boiling solution. Dissolve the salt in hot water, and decompose it with a solution of acetate of lead. Wash the precipitated malate of lead, suspend it in water, and pass sulphuretted hydrogen through the liquid until the whole of the lead is separated. Lastly, filter, and evaporate to dryness in a porcelain vessel. Malic acid, thus obtained, may be used in preparing the *malates of iron* and *manganese*, both of which have been employed medicinally in Europe.

Roses à cent feuilles, *Fr.;* Hundertblätterige Rose, *Germ.;* Rosa pallida, *Ital.;* Rosa de Alexandria, *Span.*

Rosa. *Sex. Syst.* Icosandria Polygynia.—*Nat. Ord.* Rosaceæ.

Gen. Ch. Petals five. *Calyx* urceolate, five-cleft, fleshy, contracted at the neck. *Seeds* numerous, hispid, attached to the inner side of the calyx. *Willd.*

Rosa centifolia. Willd. *Sp. Plant.* ii. 1071; Woodv. *Med. Bot.* p. 495, t. 178. This species of rose has prickly stems, usually from three to six feet high. The leaves consist of two or three pairs of leaflets, with an odd one at the end, closely attached to the common footstalk, which is rough, but without spines. The leaflets are ovate, broad, serrate, pointed, and hairy on the under surface. The flowers are large, with many petals, generally of a pale-red colour, and supported upon peduncles beset with short bristly hairs. The germ is ovate, and the segments of the calyx semi-pinnate. The varieties of *R. centifolia* are very numerous, but may be indiscriminately employed. The plant is now cultivated in gardens all over the world; but its original country is not certainly known. It has sometimes been mistaken for the damask rose, which is a distinct species.

The petals are the officinal portion. They are extremely fragrant, and have a sweetish, slightly acidulous, somewhat bitterish taste. Their odour is said to be increased by iodine. It depends on a volatile oil, which may be separated by distillation with water. (See *Oleum Rosæ.*) They should be collected when the flower is fully expanded, but has not begun to fall. Their fragrance is impaired but not lost by drying. They may be preserved fresh, for a considerable time, by compressing them with alternate layers of common salt in a well-closed vessel, or beating them with twice their weight of that substance.

The petals are slightly laxative, and are sometimes administered in the form of syrup combined with cathartic medicines; but their chief use is in the preparation of rose-water. (See *Aqua Rosæ.*)

ROSA GALLICA. *U. S.*

Red Rose.

The petals of Rosa Gallica. *U. S.*

Off. Syn. ROSÆ GALLICÆ PETALA. *Red-rose Petals.* The unexpanded petals of Rosa Gallica, fresh and dried. *Br.*

Roses rouges, *Fr.;* Französische Rose, Essig-rosen, *Germ.;* Rosa domestica, *Ital.;* Rosa rubra ó Castillara, *Span.*

Rosa. See ROSA CENTIFOLIA.

Rosa Gallica. Willd. *Sp. Plant.* ii. 1071; Woodv. *Med. Bot.* p. 498, t. 179. This species is smaller than *R. centifolia*, but resembles it in the character of its foliage. The stem is beset with short bristly prickles. The flowers are very large, with obcordate widely spreading petals, which are of a rich crimson colour, and less numerous than in the preceding species. In the centre is a crowd of yellow anthers on thread-like filaments, and as many villose styles bearing papillary stigmas. The fruit is oval, shining, and of a firm consistence. The red rose is a native of the south of Europe, and is cultivated in gardens throughout the United States.

The petals, which are the part employed, should be gathered before the flower has blown, separated from their claws, dried in a warm sun or by the fire, and kept in a dry place. Their odour, which is less fragrant than that of *R. centifolia*, is improved by drying. They have a velvety appearance, a purplish-red colour, and a pleasantly astringent and bitterish taste. Their constituents, according to M. Cartier, are tannin, gallic acid, colouring matter, a volatile oil, a fixed oil, albumen, soluble salts of potassa, insoluble salts of lime, silica, and oxide of iron. (*Journ. de Pharm.*, vii. 531.) According to M. Filhol, the astringency of red roses is ascribable less to tannic acid, of which they contain but a trace, than to quercitrin, which he obtained in notable proportion, and with which their colour is probably connected. They also contain much uncrystalli-

zable sugar. (*Repert. de Pharm.*, Mai, 1863.) The sensible properties and medical virtues of the flowers are extracted by boiling water. Their infusion is of a pale-reddish colour, which becomes bright red on the addition of sulphuric acid. As their colour is impaired by exposure to light and air, they should be kept in opaque well-closed bottles or canisters.

Medical Properties and Uses. Red roses are slightly astringent and tonic, and were formerly thought to possess peculiar virtues. They are at present chiefly employed in infusion, as an elegant vehicle for tonic and astringent medicines.

ROSMARINUS. *U. S.*

Rosemary.

The tops of Rosmarinus officinalis. *U. S.*

Romarin, *Fr.;* Rosmarin, *Germ.;* Rosmarino, *Ital.;* Romero, *Span.*

ROSMARINUS. *Sex. Syst.* Diandria Monogynia.—*Nat. Ord.* Lamiaceæ or Labiatæ.

Gen. Ch. Corolla unequal, with the upper lip two-parted. *Filaments* long, curved, simple, with a tooth. *Willd.*

Rosmarinus officinalis. Willd. *Sp. Plant.* i. 126; Woodv. *Med. Bot.* p. 329, t. 117. Rosemary is an evergreen shrub, three or four feet high, with an erect stem, divided into many long, slender, ash-coloured branches. The leaves are numerous, sessile, opposite, more than an inch long, about one-sixth of an inch broad, linear, entire, obtuse at the summit, folded backward at the edges, of a firm consistence, smooth and green on the upper surface, whitish and somewhat downy beneath. The flowers are pale-blue or white, and disposed in opposite groups, at the axils of the leaves, towards the ends of the branches. The seeds are four in number, oblong, and naked in the bottom of the calyx.

The plant grows spontaneously in the countries which border on the Mediterranean, and is cultivated in the gardens of Europe and this country. The flowering summits are the officinal portion. They have a strong balsamic odour, which is possessed, though in a less degree, by all parts of the plant. Their taste is bitter and camphorous. These properties are imparted partially to water, completely to alcohol, and depend on a volatile oil which may be obtained by distillation. (See *Oleum Rosmarini.*) The tops lose a portion of their sensible properties by drying, and become inodorous by age.

Medical Properties and Uses. Rosemary is gently stimulant, and has been considered emmenagogue. In the practice of this country it is scarcely used; but in Europe, especially on the continent, it enters into the composition of several syrups, tinctures, &c., to which it imparts its agreeable odour and excitant property. It is sometimes added to sternutatory powders, and is used externally in connection with other aromatics in the form of fomentation. In some countries it is employed as a condiment; and its flowers, which are much sought after by the bees, impart their peculiar flavour to the honey of the districts in which the plant abounds.

Off. Prep. Oleum Rosmarini. W.

ROTTLERA. *U. S. Secondary.*

Kameela.

The powder and hairs obtained from the capsules of Rottlera tinctoria (Roxburgh). *U. S.*

Off. Syn. KAMALA. *Kamala.* A powder which consists of the minute glands that cover the capsules of Rottlera tinctoria. *Br.*

This is an officinal newly introduced into the U. S. and Br. Pharmacopœias. In our own, the Latin name Rottlera has been adopted from the generic title

of the plant which yields the medicine, while the ordinary Indian name *Kameela* (often spelled *Kamala*) is used as the English synonyme. In the Br. Pharmacopœia *Kamala* is given both as the Latin and English title.

The genus Rottlera, to which the plant producing the medicine belongs, was named in honour of the Rev. Dr. Rottler, a Danish missionary, and as now recognised was established by Roxburgh. It belongs to the Natural Order of Euphorbiaceæ, and, besides the officinal R. tinctoria, includes another species having medical virtues, the *Rottlera Schimperi*, a large tree of Abyssinia, the bark of which, under the name of *cortex musenæ* or *musena bark*, has attracted some attention from its presumed anthelmintic virtues.*

Rottlera tinctoria (*Mallotus Philippinensis*, De Cand. *Prodrom.* xv. 980), which is described and figured by Roxburgh in his treatise on *The Plants of the Coast of Coromandel* (ii. 36), is a small tree from 15 to 20 feet in height, growing throughout Hindostan, in several of the E. India islands, and, it is said, in China and Australia. The fruit is a roundish three-valved, three-celled capsule, of about the size of a small cherry, marked externally with three furrows, and thickly covered with a red powder. This is the officinal part of the plant. The capsules are gathered in February and March, when full-grown, and the powder carefully brushed from them. This is largely collected in some parts of Hindostan, where it forms an important article of commerce, being extensively employed as a dye-stuff. Specimens of it, under the name of *wurrus*, were sent to England in 1852, and examined by Mr. D. Hanbury, who published an account of it in the *Pharmaceutical Journal* for June, 1853 (xii. 405). It was not till several years afterward that it began to attract attention in Great Britain as a medicine.

Properties. Kameela, as brought to our market, is a light, finely granular, and very mobile powder, of a brownish-red or madder colour, with little smell or taste, but producing a slight sense of acrimony in the mouth, and feeling gritty under the teeth. It is inflammable, and flashes almost like gunpowder when dropped into the flame of a candle. It is insoluble in cold, and but very slightly soluble in boiling water; but is dissolved by alkaline solutions, which give a resinous precipitate on the addition of an acid. Alcohol and ether dissolve a large proportion of it, forming a deep-red solution, from which water precipitates resinous matter. Under the microscope, Mr. Hanbury found it to consist of "garnet-red, semi-transparent, roundish granules, from $\frac{1}{300}$ to $\frac{1}{250}$ of an inch in diameter, more or less mixed with minute stellate hairs, and the remains of stalks and leaves, the latter of which are easily removed by careful sifting." (*Pharm. Journ.*, Feb. 1858, p. 406.) It has been examined chemically by Dr. Thos. Anderson, of Glasgow, and by G. Leube, in Germany. As given by the former, the constituents are, in 100 parts, 78·19 of resinous colouring matter, 7·34 of albumen, 7·14 of cellulose, &c., a trace of volatile oil and volatile colouring matter, 3·84 of ashes, and 3·49 of water. Of the resinous colouring substances, Dr. Anderson obtained one in a pure state by allowing a concentrated ethereal solution to stand for two days, draining and pressing in bibulous paper the resulting mass of granular crystals, and purifying them from adhering resin by repeated solution in ether and crystallization. To this substance he gave the name of *rottlerin*. It is in the form of minute crystalline plates, of a yellow colour and a satin-like lustre, insoluble in water, sparingly soluble in cold, but more so in boiling alcohol, and readily dissolved by ether, and by alkaline solutions, which assume a dark-red colour. Rottlerin melts when heated moderately,

* *Cortex Musenæ.* This bark is in quills several inches long, an inch or more in diameter, rough and fissured externally, with a brown epidermis, and beneath this successively a thin greenish cellular coat, a thicker pale-yellow periderm, and a tough very fibrous liber. It is inodorous, but has a sweetish nauseous taste, followed by an enduring sense of acrimony in the fauces. It was found by Mr. C. Thiel to contain an acrid substance analogous to saponin, a bitter principle, a fatty wax-like substance, yellow colouring matter, extractive, and various salts. It is said to be used in Abyssinia, in connection with koosso, in the treatment of the tape-worm. (*Neues Jahrb. für Pharm.* Jan. 1863, p. 374.)—*Note to the twelfth edition.*

and at a higher heat is decomposed, giving off pungent vapours. Its formula, according to Dr. Anderson, is $C_{22}H_{10}O_6$. (*Ibid.*, p. 407.) Leube found a resin soluble in ether and cold alcohol, another resin soluble in ether and boiling alcohol, starch, gum, extractive, tannin, albumen, and citric acid. He failed in obtaining the rottlerin of Dr. Anderson. The ashes were in the extraordinary proportion of 25·85 per cent., and of the ashes 83·8 per cent. consisted of insoluble silica. (*Ibid.*, Sept. 1860, p. 168.) Silica probably enters essentially into the constitution of the minute granules, and its presence accounts for their grittiness under the teeth. The active constituent is supposed to be the resin extracted by ether.

Medical Properties and Uses. Kameela is actively purgative in full doses, sometimes acting violently, and occasionally causing nausea, but seldom vomiting. It appears to have been long used in India in the treatment of tape-worm, but has been only within a few years known in Europe and this country. Its properties as a vermifuge were first investigated by Dr. C. Mackinnon, a British Army Surgeon in India, who published the results of his observations in the *Indian Annals of Medical Science*, in 1854. He found it extraordinarily efficient in the treatment of tænia, having used it in 50 cases, and failed in bringing away the worm only in two. The testimony of other practitioners in India and Great Britain goes to confirm the statements of Dr. Mackinnon, and there can be little doubt of the vermifuge powers of the medicine. It is given without previous preparation of the patient, in the dose of from one to three drachms, suspended in water, mucilage, or syrup. In the latter dose it sometimes acts violently. The worm is usually expelled dead at the third or fourth stool. If the first dose fail to operate on the bowels, it may be repeated in four hours, or followed by a dose of castor oil. Dr. Anderson, British Army Surgeon in India, has employed the medicine successfully in the form of tincture, made in the proportion of six ounces to sixteen fluidounces of rectified spirit, of which the dose is from one to four fluidrachms. As an external remedy, kameela is used by the people of India in various affections of the skin, particularly scabies. Dr. Wm. Moore, of Dublin, has employed it usefully in herpetic ring-worm. (*Dub. Hosp. Gaz.*, Nov. 15, 1857.) W.

RUBIA. *U. S. Secondary.*

Madder.

The root of Rubia tinctorum. *U. S.*

Garance, *Fr.;* Krappwurzel, *Germ.;* Robbia, *Ital.;* Rubia de tintoreros, Granza, *Span.*

Rubia. *Sex. Syst.* Tetrandria Monogynia. — *Nat. Ord.* Rubiaceæ. *Juss.* *Gen. Ch. Corolla* one-petaled, bell-shaped. *Berries* two, one-seeded. *Willd.*

Rubia tinctorum. Willd. *Sp. Plant.* i. 603; Woodv. *Med. Bot.* p. 173, t. 67.

The root of the *dyers' madder* is perennial, and consists of numerous long, succulent fibres, varying in thickness from the size of a quill to that of the little finger, and uniting at top in a common head, from which also proceed side-roots that run near the surface of the ground, and send up many annual stems. These are slender, quadrangular, jointed, procumbent, and furnished with short prickles, by which they adhere to the neighbouring plants upon which they climb. The leaves are elliptical, pointed, rough, firm, about three inches long and nearly one inch broad, having rough points on their edges and midrib, and standing at the joints of the stem in whorls of four, five, or six together. The branches rise in pairs from the same joints, and bear small yellow flowers at the summit of each of their subdivisions. The fruit is a round, shining, black berry.

The plant is a native of the south of Europe and the Levant, and is cultivated in Asia Minor, France, Holland, and the south of Italy. It is from Holland that commerce derives its chief supply. The root, which is the part used, is dug up in the third summer, and, having been deprived of its cuticle, is dried by artificial heat, and then reduced to a coarse powder. In this condition it is packed in barrels, and sent into the market. Madder from the Levant is in the state of the whole root; from the south of France, either whole or in powder. The plant is also cultivated in this country, in the States of Delaware and Ohio.

The root consists of a reddish-brown bark, and a ligneous portion within. The latter is yellow in the recent state, but becomes red when dried. The powder, as kept in the shops, is reddish-brown.

Madder has a weak peculiar odour, and a bitterish astringent taste; and imparts these properties, as well as a red colour, to water and alcohol. It contains, according to M. Runge, five distinct colouring substances; a red, a purple, an orange, a yellow, and a brown. According to M. Decaisne, only yellow colouring matter is found in the recent root; and it is under the influence of atmospheric air that this changes to red. The most interesting of the colouring substances is the *alizarin* of Robiquet and Collin. It may be obtained from the alcoholic extract by sublimation, in the method employed by Mohr in obtaining benzoic acid. (*Journ. de Pharm.*, 3e sér., xxxi. 267.) It is orange-red, inodorous, insipid, crystallizable, capable of being sublimed without change, scarcely soluble in cold water, soluble in boiling water, and very readily so in alcohol, ether, the fixed oils, and alkaline solutions. The alcoholic and watery solutions are rose-coloured; the ethereal, golden-yellow; the alkaline, violet and blue when concentrated, but violet-red when sufficiently diluted. A beautiful rose-coloured lake is produced by precipitating a mixture of the solutions of alizarin and alum. Rochleder finds a close analogy between alizarin and the chrysophanic acid of rhubarb. (See *Chem. Gaz.*, A. D. 1852, p. 243.) M. Roussin claims to have succeeded in preparing alizarin from naphthalin. (See *Am. Journ. of Pharm.*, Nov. 1861, p. 558.) Madder also contains sugar; and Döbereiner succeeded in obtaining alcohol from it by fermentation and distillation, without affecting its colouring properties. It is much used by the dyers.

Medical Properties and Uses. Madder was formerly thought to be emmenagogue and diuretic; and was used in amenorrhœa, dropsy, jaundice, and visceral obstructions. It is still occasionally prescribed in suppressed menstruation; but physicians generally have no confidence in its efficacy in this or any other complaint. When taken into the stomach it imparts a red colour to the milk and urine, and to the bones of animals, without sensibly affecting any other tissue. The effect is observable most quickly in the bones of young animals, and in those nearest the heart. Under the impression that it might effect some change in the osseous system, it has been prescribed in rachitis, but without any favourable result. The dose is about half a drachm, repeated three or four times a day. W.

RUBUS. *U. S.*

Blackberry-root.

The root of Rubus Canadensis, and of Rubus villosus. *U S.*

Rubus. *Sex. Syst.* Icosandria Polygynia.—*Nat. Ord.* Rosaceæ

Gen. Ch. Calyx five-cleft. *Petals* five. *Berry* compound, with one-seeded acini. *Willd.*

Of this extensive genus not less than twenty species are indigenous in the United States, where they are called by the various names of *raspberry*, *blackberry*, *dewberry*, *cloudberry*, &c. Most of them are shrubby or suffruticose briers, with astringent roots and edible berries; some have annual stems without prickles. The only officinal species are *R. Canadensis* and *R. villosus*, which, so far as relates to their medical properties, are so closely alike as not to require a separate description.

1. *Rubus Canadensis.* Willd. *Sp. Plant.* ii. 105; Gray, *Manual of Bot. &c.*, p. 121. — *R. trivialis.* Pursh, *Flor. Am Sept.* p. 347. The *dewberry*, sometimes also called *low blackberry*, or *creeping blackberry*, has a slender, somewhat prickly stem, which runs along the ground, and occasionally puts forth roots. The leaves are composed of three or five leaflets, which are ovate or ovate-lanceolate, generally pointed, sharply serrate, thin, and nearly smooth. The flowers are large, white, and arranged in racemes, with leaf-like bractes. The plant grows abundantly in old fields and neglected grounds in the Northern and Mid-

dle States. Its fruit is large, black, of a very pleasant flavour, and ripens somewhat earlier than that of *R. villosus.*

2. *R. villosus.* Willd. *Sp. Plant.* ii. 1085; Bigelow, *Am. Med. Bot.* i. 160; Barton, *Med. Bot.* ii. 151. The stem of the blackberry is somewhat shrubby, from three to seven feet high, branching, more or less furrowed and angular, and armed with strong prickles. The smaller branches and young shoots are herbaceous. The leaves are ternate or quinate; the leaflets ovate, acuminate, unequally and sharply serrate, and pubescent on both sides; the footstalk and midrib usually armed with short recurved prickles. The flowers are large, white, and in erect racemes, with a hairy, prickly stalk. The calyx is short, with acuminate segments. The fruit is first green, then red, and, when perfectly ripe, of a shining black colour and very pleasant taste. It is a compound berry, consisting of numerous pulpy one-seeded globules or acini attached to the receptacle. This species of Rubus is, perhaps, the most abundant of those indigenous in the United States, growing in neglected fields, along fences, on the borders of woods, in forest glades, and wherever tillage or too much shade and moisture does not interfere with it. Its flowers appear from May to July, and its fruit is ripe in August.

The berries of both these species of Rubus are much used as food; and a jelly made from them is in great esteem as an article of diet, and even as a remedy in dysenteric affections. The roots only are officinal.

The blackberry root is branching, cylindrical, of various dimensions, from nearly an inch in thickness down to the size of a straw, ligneous, and covered with a thin bark, which is externally of a light-brownish or reddish-brown colour, and in the dried root is wrinkled longitudinally. The dewberry root is usually smaller, without the longitudinal wrinkles, but with transverse fissures through the epidermis, and of a dark-ash colour, without any reddish tinge. Both are inodorous. The bark in both has a bitterish strongly astringent taste, and the ligneous portion is nearly insipid, and comparatively inert. The smaller roots, therefore, should be selected for use; or, if the thicker pieces are employed, the cortical part should be separated, and the wood rejected. Their virtues are extracted by boiling water, and by diluted alcohol, and depend chiefly, if not exclusively, upon tannin, which is an abundant constituent.

Medical Properties and Uses. Dewberry and blackberry roots are tonic and strongly astringent. They have long been a favourite domestic remedy in bowel affections, and from popular favour have passed into regular medical use. Given in decoction, they are usually acceptable to the stomach, without being offensive to the taste; and may be employed with great advantage in cases of diarrhœa from relaxation of the bowels, whether in children or adults. We can add our own decided testimony to that of others who have spoken favourably of their use in this complaint; and there is no doubt that they are applicable to all other cases in which the vegetable astringents are found serviceable. The decoction may be prepared by boiling an ounce of the smaller roots, or of the bark of the larger, in a pint and a half of water down to a pint; of which from one to two fluidounces may be given to an adult three or four times, or more frequently, during the twenty-four hours. The dose of the powdered root is 20 or 30 grains. A fluid extract may be prepared from the root, in the same manner and proportions exactly as the officinal fluid extract of Bittersweet (see *Extractum Dulcamaræ Fluidum*), and given in the dose of 30 minims.* The syrup is officinal.

Off. Prep. Syrupus Rubi, *U. S.* W.

* *Aromatic Syrup of Blackberry.* Take of Blackberry Root ℥ij; Cinnamon, Cloves, each, ʒiss; Mace ʒi; Sugar ℥xxx. Reduce the root and spices to a powder which will pass through a sieve of 50 meshes to the square inch, moisten this with two fluidounces of alcohol, put into a percolator, and displace with water till 17 fluidounces have passed, and dissolve the sugar in the filtrate. A fluidounce is equivalent to 30 grains of the root. (*Am. Journ. of Pharm.*, Nov. 1859, p. 552.)—*Note to the twelfth edition.*

RUMEX. *U. S. Secondary.*

Yellow Dock.

The root of Rumex crispus. *U. S.*

RUMEX. *Sex. Syst.* Hexandria Trigynia. — *Nat. Ord.* Polygonaceæ.

Gen. Ch. Calyx three-leaved. *Petals* three, converging. *Seed* one, three-sided. *Willd. Calyx* six-parted, persistent, the three interior divisions petaloid, connivent. *Seed* one, three-sided, superior, naked. *Stigmata* multifid. *Nuttall.*

Several species of Rumex have sour leaves, and are distinguished by the common name of *sorrel* from the others, which are called *dock*. Of the former, *Rumex Acetosa*, or *common English sorrel*, formerly held a place in the London and Dublin Pharmacopœias. *R. Acetosella* is the common sorrel of our fields, though supposed to have been originally introduced from Europe. The leaves of both these plants are agreeably sour to the taste, and owe their acidity to binoxalate of potassa with a little tartaric acid. They quite lose this taste in drying. They are refrigerant and diuretic, and may be used advantageously as an article of diet in scurvy. For this purpose they are prepared in the form of salad. The juice of the leaves forms with water an agreeable acidulous drink, sometimes used in fevers. Taken very largely, the leaves are said to have produced poisonous effects. (See *Wood's Quarterly Retrospect*, i. 109.) *R. scutatus* also ranks among the sorrels.

Of the proper docks, though one only is recognised by the Pharmacopœia, several others have been used. The roots of *R. Patientia* and *R. Alpinus*, European plants, and of *R. aquaticus*, *R. acutus*, and *R. sanguineus*, belonging both to Europe and the United States, may be employed indiscriminately with those of the officinal species. *R. Britannica* and *R. obtusifolius* were formerly officinal, but were dismissed at the late revision of the Pharmacopœia, and the present officinal species adopted in their place. *R. Hydrolapathum* (Hudson), which is the *R. aquaticus* of the late Dublin Pharmacopœia, is thought to be the *Herba Britannica* of the ancients, celebrated for the cure of scurvy and diseases of the skin. The docks are herbaceous plants with perennial roots. Their flowers are in terminal or axillary panicles. Some of the species are dicœcious; but the one here described has perfect flowers.

Rumex crispus. Willd. *Sp. Plant.* ii. 251; Gray, *Manual of Botany, &c.*, p. 377. From a perennial, spindle-shaped, yellow root, which penetrates deeply into the ground, a stem rises annually, three or four feet high, furnished with smooth, lanceolate leaves, strongly waved at their margins, and terminating in panicled racemes of small, inconspicuous, greenish flowers. The lower leaves are truncate or cordate at the base, and those which spring from the root have long footstalks. The flowers are in crowded whorls, upon long wand-like racemes, which are leafless above. The valves or inner sepals of the calyx are roundish-cordate, entire or slightly denticulate, and one or all grain-bearing. This species of dock is a native of Europe, but has become naturalized in this country, and is now a common weed, growing in roads and fields.

Dock root, from whatever species derived, has an astringent, bitter taste, with little or no smell. It readily yields its virtues to water by decoction. According to Riegel, the root of *R. obtusifolius* contains a peculiar principle called *rumicin*, resin, extractive matter resembling tannin, starch, mucilage, albumen, lignin, sulphur, and various salts, among which are phosphate of lime, and different acetates and malates. (*Journ. de Pharm.*, 3e sér., i. 410.) Rumicin, in its pure state, has since been ascertained by Karl von Thann, to be identical with chrysophanic acid. (See *Rheum.*) (*Chem. Central Blatt*, Nov. 10, 1858, p. 795.) The leaves of most of the species are edible when young, and are occasionally used as spinage. They are somewhat laxative, and form an excellent diet in scorbutic cases. The roots are used to dye a yellow colour.

The officinal species, R. crispus, has been carefully examined by Dr. J. H. Salisbury, of New York; and the following statements are derived from his

paper, published in the *New York Journal of Medicine* (March, 1855, p. 211). The seeds are astringent, but less bitter than the root. The leaves are bitterish, pungent, and astringent to the taste, with a smell like that of bruised sorrel. The petioles are decidedly sour, and contain nearly one per cent. of oxalic acid. The root, which is the officinal part, is spindle-shaped, yellow, and covered with an easily separable and nearly tasteless epidermis, within which are successively the cortical layers, a ligneous portion, and a central medulla. The cortical part, which is easily separated, fleshy, and tender, is the most active. It has a bitter and astringent taste, and yielded, on analysis, starch, a little sugar, albuminous matter, gummy matter, bitter extractive, tannic acid of the kind which gives green precipitates with the salts of iron, lignin, and various salts. The root yields its virtues to water and alcohol, but is injured by long boiling.

Medical Properties and Uses. Dock root is astringent, and gently tonic, and is also supposed to possess an alterative property, which renders it useful in scorbutic disorders, and cutaneous eruptions, particularly the itch, in the cure of which it enjoyed at one time considerable reputation. It is said to have proved useful in scrofula and syphilis. Dr. Thomson found a decoction of the root of *R. Patientia* very efficacious in obstinate ichthyosis. *R. aquaticus* and *R. Britannica* are the most astringent. The roots of some species unite a laxative with the tonic and astringent property, resembling rhubarb somewhat in their operation. Such are those of *R. crispus* and *R. obtusifolius;* and *R. Alpinus* has in some parts of Europe the name of *mountain rhubarb.* This resemblance is not singular, as the two genera belong to the same natural family. Dock root is given in powder or decoction. Two ounces of the fresh root bruised, or one ounce of the dried, may be boiled in a pint of water, of which two fluidounces may be given at a dose, and repeated as the stomach will bear it. The root has often been applied externally in the shape of ointment, cataplasm, and decoction, to the cutaneous eruptions and ulcerations for which it has been used internally. The powdered root is recommended as a dentifrice, especially when the gums are spongy. W.

RUTA. *U. S. Secondary.*

Rue.

The leaves of Ruta graveolens. *U. S.*

Rue odorante, *Fr.;* Garten-Raute, *Germ.;* Ruta, *Ital.;* Ruda, *Span.*

Ruta. *Sex. Syst.* Decandria Monogynia. — *Nat. Ord.* Rutaceæ.

Gen. Ch. Calyx five-parted. *Petals* concave. *Receptacle* surrounded by ten melliferous points. *Capsule* lobed. *Willd.*

Ruta graveolens. Willd. *Sp. Plant.* ii. 542; Woodv. *Med. Bot.* p. 487, t. 174. Common rue is a perennial plant, usually two or three feet high, with several shrubby branching stems, which, near the base, are woody and covered with a rough bark, but in their ultimate ramifications are smooth, green, and herbaceous. The leaves are doubly pinnate, glaucous, with obovate, sessile, obscurely crenate, somewhat thick and fleshy leaflets. The flowers are yellow, and disposed in a terminal branched corymb upon subdividing peduncles. The calyx is persistent, with four or five acute segments; the corolla consists of four or five concave petals, somewhat sinuate at the margin. There are usually ten stamens, but sometimes only eight. The plant is a native of the south of Europe, but cultivated in our gardens. It flowers from June to September. The whole herb is active; but the leaves are usually employed.

These have a strong disagreeable odour, especially when rubbed. Their taste is bitter, hot, and acrid. When recent, and in full vigour, they have so much acrimony as to inflame and even blister the skin, if much handled; but the acrimony is diminished by drying. Their virtues depend chiefly on a volatile oil, which is very abundant, and is contained in glandular vesicles, apparent over the whole surface of the plant. (See *Oleum Rutæ.*) They contain, also, according to Mähl, chlorophyll, albumen, an azotized substance, extractive, gum, starch or inulin, malic acid, and lignin; and, according to Bornträger, a peculiar acid

which he calls *rutinic acid*. (*Chem. Gazette*, Sept. 1845, p. 385.) Rutinic acid is the colouring principle of rue, and has been found in various other plants. It was thought, at one time, that it might be identical with quercitrin; but, though analogous to that principle, it has been shown to be distinct. Like quercitrin, it seems to play an important part in the colouring of plants. (*Journ. de Pharm.*, Août, 1862, p. 165.) Both alcohol and water extract their active properties.

Medical Properties and Uses. Rue is stimulant and antispasmodic, and, like most other substances which excite the circulation, occasionally increases the secretions, especially when deficient from debility. It appears to have a tendency to act upon the uterus; in moderate doses proving emmenagogue, and in larger, producing a degree of irritation in the organ which sometimes determines abortion. Taken very largely it acts as an acrid narcotic poison. Three cases are recorded by Dr. Hélie in which it was taken by pregnant women, with the effect of producing dangerous gastro-intestinal inflammation and cerebral derangement, which continued for several days, but ended at length in recovery. In each instance miscarriage resulted. Great depression and slowness of the pulse attended the narcotic action of the poison. In one of these cases, three fresh roots of the size of the finger were used in the form of decoction. (*Ann. d'Hyg. Pub. et de Méd. Lég.*, xx. 180.) A case is recorded by Dr. G. F. Cooper in the *Nashville Journ. of Med. and Surg.*, in which a man, convalescent from dysentery, having added some brandy to a handful of the bruised herb, expressed it, and took the whole of the liquor, with fatal effects. The prominent symptoms were vomiting, violent tormina, tenesmus with bloody stools, abdominal distension with tenderness, and severe strangury. (*Med. Exam.*, N. S., ix. 720.) Rue is sometimes used in hysterical affections, worms, flatulent colic, and amenorrhœa, particularly in the last complaint. It has also been highly recommended in uterine hemorrhage, especially when dependent on an atonic state of the organ. The ancients employed it as a condiment, and believed it to possess, besides other valuable properties, that of resisting the action of poisons. Its excitant and irritating properties require that it should be used with caution. The dose of the powder is from fifteen to thirty grains two or three times a day. The medicine is also given in infusion and in extract. W.

SABADILLA. *U. S., Br.*

Cevadilla.

The seed of Veratrum Sabadilla. *U. S.* The dried Fruit of Asagræa officinalis. *Br.*

Cévadille, *Fr.;* Sabadillsame, *Germ.;* Cebadilla, *Span.*

There has been much uncertainty in relation to the botanical origin of cevadilla. At one time it was generally believed to be derived from *Veratrum Sabadilla*, which is recognised in the U. S. Pharmacopœia. But Schiede, during his travels in Mexico, ascertained that it was, in part at least, collected from a different plant, of the same natural order of Melanthaceæ, growing upon the eastern declivity of the Mexican Andes. This was considered by Schlechtendahl as another species of Veratrum, by Don as an Helonias, and by Lindley as belonging to a new genus which he named Asagræa. Hence it has been variously denominated *Veratrum officinale*, *Helonias officinalis*, and *Asagræa officinalis*. The Edinburgh College recognised this plant, under Don's title of Helonias officinalis, as one of the sources of cevadilla; in the present British Pharmacopœia it is admitted, under Lindley's name of Asagræa officinalis, as the only source. More exact information, however, is wanted before we can determine its precise origin. It has been adopted in the Pharmacopœias solely on account of its employment in the preparation of veratria. It is brought from Vera Cruz.*

* Until more definite information is obtained on the subject, we give in a note a brief description of the two plants above referred to.

Veratrum Sabadilla. Retzius, *Obs.* i. 31; Carson, *Illust. of Med. Bot.* ii. 50, pl. 94. See *Veratrum Album.* The leaves of this plant are numerous, ovate-oblong, obtuse, with from eight to fourteen ribs, glaucous beneath, and all radical. The flower-stem is erect, simple,

Cevadilla seeds usually occur in commerce mixed with the fruit. This consists of three coalescing capsules or follicles, which open above, and appear like a single capsule with three cells. It is three or four lines long and a line and a half in thickness, obtuse at the base, light-brown or yellowish, smooth, and in each capsule contains one or two seeds. A resemblance, existing or supposed, between this fruit and that of barley is said to have given rise to the Spanish name cevadilla, which is a diminutive of barley. The seeds are elongated, pointed at each end, flat on one side and convex on the other, somewhat curved, two or three lines long, wrinkled, slightly winged, black or dark-brown on the outside, whitish within, hard, inodorous, and of an exceedingly acrid, burning, and durable taste. Cevadilla was found by Pelletier and Caventou to contain a peculiar organic alkali which they named *veratria*, combined with gallic acid; fatty matter, consisting of olein, stearin, and a peculiar volatile fatty acid denominated *cevadic* or *sabadillic acid;* wax; yellow colouring matter; gum; lignin; and salts of potassa and of lime, with a little silica. From 100 parts of the seeds, separated from their capsules, Meissner obtained 0·58 of veratria. M. Couërbe discovered another alkaloid in the seeds which he denominated *sabadillin*. Besides the principles above mentioned, a peculiar acid was discovered by Merck, called *veratric acid*, which is in colourless crystals, fusible and volatilizable without decomposition, but slightly soluble in cold water, more soluble in hot water, soluble in alcohol, insoluble in ether, having the properties of reddening litmus paper, and forming soluble salts with the alkalies. For an account of the mode of preparing veratria, its properties, and remedial applications, and for a more particular notice of sabadillin (*sabadillia*), see *Veratria* in *Part* II.

Medical Properties and Uses. Cevadilla is an acrid, drastic emeto-cathartic, operating occasionally with great violence, and in overdoses capable of producing fatal effects. It was known as a medicine in Europe so early as the year 1572; but has never been much employed. It has been used chiefly as an anthelmintic, especially in cases of tænia, in which it has been given in doses varying from five to thirty grains. It has also been given in different nervous affections It is the principal ingredient of the *pulvis Capucinorum*, sometimes used in Europe for the destruction of vermin in the hair. It is considered by the Mexicans useful in hydrophobia, and was employed by M. Fouilhoux, of Lyons, in a supposed case of that disease, in the dose of about nine grains, with asserted success. Externally applied, it is highly irritating, and is even said to be corrosive. Its chief employment at present is for the preparation of veratria.

SABBATIA. *U. S.*

Sabbatia. American Centaury.

The herb of Sabbatia angularis. *U. S.*

Sabbatia. *Sex. Syst.* Pentandria Monogynia. — *Nat. Ord.* Gentianaceæ.

and round, rises three or four feet in height, and bears a spreading, simple, or but slightly branched panicle of somewhat nodding flowers, supported upon very short pedicels. The flowers, which are of a blackish-purple colour, approximate in twos and threes, the fertile turning at length to one side, and the sterile falling off. The segments of the corolla are ovate-lanceolate, and without veins. The capsules occupy only one side of the stem. This plant grows in Mexico and the West Indies, and was cultivated by Descourtilz at San Domingo, from seeds obtained in Mexico.

Asagræa officinalis. Lindley, *Botan. Reg.*, June, 1839.—*Veratrum officinale.* Schlechtendahl, *Linnæa*, vi. 45.—*Helonias officinalis.* Don, *Ed. New Philos. Journ.*, October, 1832, p. 234. The following is the generic character given by Lindley. "*Flowers* polygamous, racemose, naked. *Perianth* six-partite, segments linear, veinless, almost equal, with a nectariferous excavation at the base, equal to the stamens. *Stamens* alternately shorter; anthers cordate as if unilocular, after dehiscence shield-shaped. *Ovaries* three, quite simple, attenuated into an obscure stigma. *Follicles* three, acuminate, papery; seeds scimitar-shaped, corrugated, winged. Bulbous herbs, with grass-like leaves, and small, pale, and densely racemed flowers." *A. officinalis*, which is the only known species, has linear, acuminate, subcarinate leaves, roughish at the margin, and four feet in length by three lines in breadth, and a round flower-stem, about six feet high, terminating in a very dense, straight, spike-like raceme, eighteen inches long. The flowers are white, with yellow anthers.

Gen. Ch. Calyx five to twelve-parted. *Corolla* rotate, five to twelve-parted. *Stigmas* two, spiral. *Anthers* at length revolute. *Capsule* one-celled, two-valved, many-seeded. *Nuttall.*

Sabbatia angularis. Pursh, *Flor. Am. Sept.* 137; Bigelow, *Am. Med. Bot.* iii. 147; Barton, *Med. Bot.* i. 255.— *Chironia angularis.* Linn. The American centaury is an annual or biennial herbaceous plant, with a fibrous root, and an erect, smooth, four-sided stem, winged at the angles, simple below, sending off opposite axillary branches above, and one or two feet in height. The leaves, which vary considerably in length and width, are ovate, entire, acute, nerved, smooth, opposite, and sessile, embracing half the circumference of the stem at their base. The flowers are numerous, growing on the ends of the branches, and forming together a large terminal corymb. The calyx is divided into five lanceolate segments, considerably shorter than the corolla. This is deeply five-parted, with obovate segments of a delicate rose-colour, which is paler and almost white in the middle of their under-surface. The anthers are yellow, and, after shedding their pollen, become revolute. The style, which is bent downward, and is longer than the stamens, terminates in two linear stigmas, which become spirally twisted together. The plant is widely diffused through the Middle and Southern States, growing in low meadow grounds, and, in wet seasons, upon uplands, in woods, and neglected fields. It flowers in July and August. In its general aspect as well as medical properties, it bears a close resemblance to *Erythræa Centaurium*, or European centaury, for which it was mistaken by the earlier settlers. The whole herb is employed, and should be collected when in flower.

All parts of it have a strongly bitter taste, without any admixture of astringency, or other peculiar flavour. Both alcohol and water extract its bitterness, together with its medical virtues.

Medical Properties and Uses. American centaury has the tonic properties of the simple bitters, and is very analogous in its action to the other plants of the same natural family. It has long been popularly employed as a prophylactic and remedy in our autumnal intermittent and remittent fevers; and was formerly much esteemed by some physicians in the latter of these complaints. The condition to which it was considered applicable was that existing between the paroxysms, when the remission was such as to call for tonics, but was not deemed sufficient to justify a resort to the preparations of Peruvian bark. It is occasionally useful, during the progress of a slow convalescence, by promoting appetite and invigorating digestion; and may be employed for the same purpose in dyspepsia and diseases of debility. The most convenient form for administration is that of infusion. A pint of boiling water, poured on an ounce of the herb and allowed to cool, may be given in the dose of two fluidounces, repeated every hour or two during the remission of fevers, and less frequently in chronic affections. The dose of the powder is from thirty grains to a drachm. The decoction, extract, and tincture are also efficient preparations. W.

JUNIPERUS. See JUNIPERUS.

Juniperus Sabina. Willd. *Sp. Plant.* iv. 852; Woodv. *Med. Bot.* p. 10, t. 5. This is an evergreen shrub, from three to fifteen feet high, with numerous erect, pliant branches, much subdivided. The bark of the young branches is light-green, that of the trunk rough, and reddish-brown. The leaves, which completely invest the younger branches, are numerous, small, erect, firm, smooth, pointed, dark-green, glandular in the middle, opposite, and imbricated in four rows. The flowers are male and female on different trees. The fruit is a blackish-purple

berry, of an ovoid shape, marked with tubercles and the remains of the calyx and petals, and containing three seeds.

The savine is a native of the south of Europe and the Levant, and is said to grow wild in the neighbourhood of our northwestern lakes. The ends of the branches, and the leaves by which they are invested, are collected for medical use in the spring. When dried they fade very much in colour.

The tops of *Juniperus Virginiana*, or common red cedar, are sometimes substituted in the shops for savine, to which they bear so close a resemblance as to be with difficulty distinguished. The two species, however, differ in their taste and smell. In *J. Virginiana*, moreover, the leaves are sometimes ternate.

The tops and leaves of the savine plant have a strong, heavy, disagreeable odour, and a bitter, acrid taste. These properties, which are less striking in the dried than the recent leaves, are owing to a volatile oil, which is obtained by distillation with water. (See *Oleum Sabinæ.*) The leaves impart their virtues to alcohol and water. From an analysis by Mr. C. H. Needles, they appear to contain volatile oil, gum, tannic or gallic acid, resin, chlorophyll, fixed oil, bitter extractive, lime, and salts of potassa. (*Am. Journ. of Pharm.*, xiii. 15.)

Medical Properties and Uses. Savine is highly stimulant, increasing most of the secretions, especially those of the skin and uterus, to the latter of which it is supposed to have a peculiar direction. It has been much used in amenorrhœa, and occasionally as a remedy for worms. Dr. Chapman strongly recommended it in chronic rheumatism; and it is employed in Germany, both internally and externally, in chronic gout. In overdoses it may produce dangerous gastro-intestinal inflammation, and should therefore be used with caution. In no case should it be employed when much general or local excitement exists. In pregnancy it should always be given with great caution; though it has recently been recommended as an effective remedy in certain forms of menorrhagia, and is asserted to prove occasionally useful in preventing threatened abortion. (See *Am. Journ. of Med. Sci.*, N. S., viii. 475.) It is most conveniently administered in the form of powder, of which the dose is from five to fifteen grains, three or four times a day. A fluid extract has been prepared by Mr. J. J. Grahame, which may be given in the same number of drops.*

As an external irritant it is useful, in the form of cerate, for maintaining a discharge from blistered surfaces; but as the preparation sold in this country under the name of savine ointment is often feeble, either from the age of the drug, or the substitution of red cedar, it has in some measure fallen into disrepute. (See *Ceratum Sabinæ.*) In powder or infusion, savine is used in Europe as an application to warts, indolent, carious, and gangrenous ulcers, psora, and tinea capitis; and the expressed juice of the fresh leaves, diluted with water, is sometimes applied to similar purposes.

Mélasse, *Fr.;* Zuckersatz, Zuckersyrup, *Germ.;* Melazzo, *Ital.;* Melaca, *Span.*

Among the saccharine principles distinguished by the chemist are cane sugar, or sugar properly so called, derived from the sugar cane, the beet, and the sugar maple; glucose or grape sugar, with which starch sugar, diabetic sugar, the crystallizable sugar of honey, and the saccharine matter of the glucosides are identical; uncrystallizable sugar; sorbite, from the berries of the mountain ash (*Sorbus aucuparia*); lactin, or sugar of milk; inosite, or sugar of muscular flesh; mannite, with which mushroom sugar is identical; and glycerin. *Glucose* or *grape sugar* is conveniently obtained by spreading crystalline honey on porous tiles, dissolving what remains on their surface in alcohol, and crystallizing. The product is about one-fourth of the weight of the honey. It is also largely prepared from starch by the action of very weak sulphuric acid at a high temperature. (See *Am. Journ. of Pharm.*, Jan. 1866, p. 1.) Glucose, as obtained from a concentrated syrup, is in the form of crystalline grains; but, when crystallized from its alcoholic solution, it has the shape of square tables or cubes. It is less sweet than cane sugar. It is also less soluble in water, and much more soluble in alcohol. It has the sp. gr. 1·386. Strong mineral acids hardly act on grape sugar, but destroy cane sugar with facility. On the other hand, grape sugar is destroyed by alkalies, with which cane sugar forms definite compounds. Dissolved in water and subjected to prolonged ebullition, grape sugar undergoes very little alteration. Its solution rotates the plane of polarization of polarized light to the right, and is capable of undergoing the vinous fermentation directly, without passing through any intermediate state. It is characterized, also, in boiling solution, by reducing the potassa-tartrate of copper, and by becoming brown by the action of the alkalies. The name of *glucosides* has been given to certain organic substances which are resolvable, by the presence of acids, or other slight chemical influence, into glucose and some other proximate principle, as in the instance of tannic acid, which is resolved into glucose and gallic acid. *Uncrystallizable sugar* (*fruit sugar* or *chulariose*), an isomeric form of glucose, found in honey and the juice of fruits, is generated from cane sugar by solution in water or weak acids, and long boiling. Hence it is present in molasses. An aqueous solution of this sugar turns the plane of polarization to the left, and, like grape sugar, is susceptible of the vinous fermentation without an intermediate change. In consequence of this effect on polarized light, it has been named by the French chemists *inverse sugar* (*sucre interverté*); its rotatory power being the reverse of that of the sugar from which it is produced. Uncrystallizable sugar is transformed into grape sugar, when it is made to assume a crystalline structure, but not by mere solidification. (*Soubeiran.*) A solution of *cane sugar*, like that of grape sugar, has a rotating power to the right. When it ferments, it is not, as is generally supposed, first converted into grape sugar. It is found both by Mitscherlich and Soubeiran to be first changed into uncrystallizable sugar; and, as the change proceeds, the rotating power to the right of the cane sugar gradually lessens and disappears, and is replaced by the rotating power to the left of the uncrystallizable sugar formed. *Sorbin*, discovered by M. Pelouze, is in perfectly transparent crystals, having the same taste as cane sugar, but is not susceptible of fermentation. *Lactin*, or *sugar of milk*, is now officinal. (See *Saccharum Lactis.*) *Inosite* is a sugar found in the juice of flesh. For a description of *mannite* and *glycerin*, see the articles *Manna* and *Glycerina.*

one fluidounce, and mix this with the residue of the portion reserved. One fluidrachm of the fluid extract represents 60 grains of the savine. (*Trans. of Maryland Col. of Pharm.*, June, 1868.)—*Note to the twelfth edition.*

Besides the sugars enumerated, chemical writers mention *dulcose* (*dulcite* or *dulcin*), a substance like mannite from an unknown plant of Madagascar; *phycite*, obtained from Protococcus vulgaris; *quercite*, obtained from acorns; *melampyrite*, from *Melampyrum nemorosum* and other Scrophularineæ; *mycose* or the sugar of ergot; *melitose*, the peculiar sugar of Australian manna, at first thought to be grape sugar; *trehalose*, the crystallizable principle of Turkish manna; *melizotose*, in Briançon manna; *pinite*, obtained from a sugar of California, said to be derived from Pinus Lambertiana; and *phaseomannite*, obtained from kidney beans before they are ripe. Of these saccharine substances, melitose, trehalose, mycose, and melizotose, though differing in some of their properties from cane sugar, agree with it in composition, and in the property of being modified by acids, and transformed into sugars analogous to glucose. (Berthelot, *Journ. de Pharm.*, Oct. 1858, p. 292.)* In relation to *melampyrite*, the latest researches give reason to think that it is identical with dulcite. (Gmelin, *Handbook*, xv. 543.)

Cane sugar is manufactured extensively on the continent of Europe from the beet, and in considerable quantities, in Canada and the northern and northwestern parts of the United States, from the sap of the sugar maple (*Acer saccharinum*). In the year 1850, according to the census returns, thirty-four millions of pounds of crude maple sugar were made within the limits of the United States.† Cane sugar may also be obtained from cornstalks, and from the *Chinese sugar cane*, or *Sorghus saccharatus*. The juice of the latter contains from 10 to 16 per cent. of sugar, crystallizable and uncrystallizable, the latter greatly predominating. Hence it is not well suited to produce crystallized sugar, but yields molasses abundantly. It also affords good grain for bread, and excellent fodder for domestic animals. In India sugar is made from the sap of different species of palm. In 1844 more than 6000 tons of crude *palm sugar*, called *jaggary*, were manufactured. It is more easily refined, and at less cost than the sugar from the cane. (*Stevens.*) But the supply of sugar from these sources is insignificant, when compared with that obtained from the sugar cane itself, which is extensively cultivated in the East and West Indies, Brazil, and some of our Southern States, particularly Louisiana. This plant is the *Saccharum officinarum* of botanists, and is the source of the officinal sugar of the Pharmacopœias.

Saccharum. *Sex. Syst.* Triandria Digynia. — *Nat. Ord.* Graminaceæ.

Gen. Ch. Calyx two-valved, involucred, with long down. *Corolla* two-valved. *Willd.*

Saccharum officinarum. Willd. *Sp. Plant.* i. 321; *Philos. Trans* lxix. 207. The *sugar cane* is an herbaceous plant, possessing a jointed, succulent root, from which arise several shining, jointed, solid stems, from an inch to two inches in diameter, and from six to twelve feet high, and containing a white and juicy pith. The colour of the stem is yellow, greenish-yellow, purple, or striped. The joints are about three inches apart, and give origin to the leaves, which embrace the stem at their base, are three or four feet long and about an inch wide, flat, acuminate, longitudinally striated, furnished with a white midrib, glabrous, finely dentate, and of a green colour inclining to yellow. The flowers are pinkish, surrounded by a long silky down, and disposed in a large, terminal, nearly pyramidal panicle, composed of subdivided spikes, and two or three feet in length. The plant has a general resemblance to the Indian corn. Four varieties are mentioned; 1. the *common*, with a yellow stem; 2. the *purple*, with a purple stem and richer juice; 3. the *gigantic*, with a very large light-coloured stem; and 4. the *Otaheitan*, which was introduced into the West Indies from the island of Tahiti (Otaheite) by Bougainville and Bligh, and is distinguished by its greater height, the longer intervals between its joints, and the greater length of the hairs which surround the flowers.

* In relation to the fermentation of several of the sugars, in presence of chalk and certain animal substances, such as cheese, &c., the reader is referred to some interesting observations of M. Berthelot, contained in the *Journ. de Pharm.* for Oct. 1856.

† In relation to the preparation of maple sugar, see a paper by Dr Geo. D. Gibb in the *Br. Am. Journ. of Med. Sci* (July, 1851), and another by M. J. B Avequin in the *Am. Journ. of Pharm.* (Jan. 1858, p. 72).—*Note to the twelfth edition.*

The sugar cane is cultivated by cuttings, which are planted in rows, and which, by giving rise to successive shoots, furnish five or six crops before the plants require to be renewed. At the end of a year the plant generally flowers, and in four or five months afterwards the canes are completely ripe, at which time they have a yellowish colour, and contain a sweet viscid juice. The quantity of sugar which they yield is variable. According to Avequin, of New Orleans, the proportion of cane sugar in the recent stalk is about 10 per cent., of uncrystallizable sugar from 3½ to 4 per cent. Cane juice is said to contain from 17 to 23 per cent. of crystallizable sugar, though scarcely 7 per cent. is extracted in practice.

Preparation and Purification. The canes, when ripe, are cut down close to the earth, topped, and stripped of their leaves, and then crushed between vertical iron rollers in a mill. The juice, constituting 90 per cent. of the cane, though scarcely 50 per cent. is actually obtained, is of a pale-greenish colour, sweet taste, and balsamic odour, and has a sp. gr. varying from 1·033 to 1·106. As it runs out it is received in suitable vessels, and, being quickly removed, is *immediately* mixed with lime, in the form of milk of lime, in the proportion of about 1 part of the earth to 800 of the juice, and heated in a boiler to 140°. The exact proportion of the lime cannot be determined, as the juice varies in quality in different seasons; but the manufacturer should aim at making the liquor neutral, or very slightly alkaline. The gluten and albumen rise to the top, and form a thick scum, from underneath which the liquid is drawn off by a cock into a copper boiler, where it is concentrated by heat, the scum being carefully skimmed off as it forms. Filtering the juice through cloth filters before heating it is advantageous. When sufficiently concentrated, the juice is transferred to shallow vessels called coolers, from which, when it assumes a granular aspect, it is drawn off into wooden vessels with perforated bottoms, the holes in which are temporarily plugged. At the end of twenty-four hours, the liquid is strongly agitated with wooden stirrers, in order to accelerate the granulation of the sugar, which is completed in six hours. The stoppers are now removed, and the syrup is allowed to drain off from the sugar, which in this state is granular, of a yellowish colour, and moist. It is next dried in the sun, and being introduced into hogsheads, forms the *brown sugar* of commerce. The syrup, by a new evaporation, furnishes an additional portion of sugar; and the liquid which finally remains, incapable of yielding more sugar with advantage, is called *molasses*. Eight pounds of the juice yield, on an average, one pound of brown sugar. In the process of extraction, it is important that the juice should be concentrated by a moderate heat; as a high temperature causes more of the cane sugar to be converted into uncrystallizable sugar, and, therefore, increases the amount of the molasses. This conversion takes place slowly, even in the cold, if the juice is allowed to stand; and hence the importance of manufacturing it at once into sugar. According to M. Maumené, the cane sugar in crude beet juice may be preserved without change by converting it into saccharate of lime; and he supposes that this is true of all vegetable juices, containing cane sugar. In the case of beet juice, he recommends the addition of an amount of slaked lime, equal to half the weight of the sugar supposed to be present; an amount which will be about 5 per cent. of the weignt of the juice. When the juice is to be manufactured, the sugar is set free by saturating nine-tenths of the lime with carbonic, phosphoric, or sulphuric acid. (*Journ. de Pharm.*, Nov. 1856.) It may be set free also by animal charcoal, which is now generally employed for the purpose. A mode of evaporating cane juice is said to have been adopted in Antigua by Mr. Alfred Fryer, by which it seems that the change into uncrystallizable sugar is altogether avoided, and a great saving is thus effected. The precise steps of the process are not given; but it would appear to consist in a very rapid evaporation to absolute dryness, by means of heated air. The sugar thus prepared is in solid mass. (*Chem. News*, June 30, 1865, p. 302.)

Brown sugar is sometimes partially purified by boiling it with lime-water, and, after sufficient concentration, allowing the syrup to crystallize in large in-

verted conical vessels, pierced at the apex and plugged. The surface of the crystalline mass being covered with a thin mixture of clay and water, the plug is removed, and the water from the clay, percolating the mass, removes the coloured syrup, which flows out at the hole. Sugar, thus prepared, approaches to the white state, and constitutes the clayed sugar of commerce, usually called, in this country, *Havana sugar.*

There is no doubt that a large proportion of the sugar is lost in the ordinary process of manufacture; and several plans have been proposed to prevent this loss. In December, 1847, Dr. John Scoffern, of England, took out a patent for the use of subacetate of lead as a purifying agent, added to the cane juice in the proportion of one-sixth of 1 per cent. When applied to cane juice, it separates the impurities completely, thus avoiding the labour of skimming, and furnishes the whole of the sugar, instead of about one-third, as by the ordinary process. When used in refining operations, it enables the refiner to work up residues, which would not furnish sufficient sugar to repay the cost of the old process. The lead is finally removed from the sugar solutions in the form of sulphite of lead by the action of sulphurous acid gas, forced through them by mechanical means. In this way Dr. Scoffern alleges that the whole of the lead may be separated; but even if it is not, he believes that a minute proportion of sulphite of lead in the sugar would not prove injurious. In this opinion he is supported by several eminent chemists and physicians; but the position is controverted by others equally eminent, and, we think, on just grounds; as we should feel doubt of the wholesomeness of an aliment so extensively used as sugar, containing a proportion of lead, however minute. Such is the view taken in France, where the process of Dr. Scoffern is prohibited. Another patented process for the defecation of cane juice, and of the syrups of sugar refineries, is that of R. & J. Oxland, in which acetate of alumina is used. The details of the process are given in the *Chem. Gazette* for Nov. 16, 1849, to which the reader is referred. M. Melsens, of Brussels, has proposed a third process, which consists in the use of bisulphite of lime. This salt is alleged to act as an antiseptic, preventing the operation of any ferment; as an absorber of oxygen, opposing the action of that gas on the juice; as a clarifier, rendering insoluble at 212° all coagulable matters; as a bleacher of pre-existing colouring matters, and a preventive of the formation of new ones; and, lastly, as a substance furnishing a base to neutralize hurtful acids, which unite with the lime, displacing the weaker sulphurous acid. M. Melsens admits that he has made his experiments with cane juice on a small scale only, and, therefore, leaves the application of the principles of his method to the intelligence of the manufacturers themselves. M. Emil Pfeiffer has proposed another refining process, which consists in the use of superphosphate of lime, an agent previously recommended by Brande. (See *Chem. Gaz.*, April 15, 1856.) M. Emile Rousseau proposes sulphate of lime as the best addition to saccharine juices in the manufacture of sugar. This coagulates the albuminous matters. The clear juice is then agitated with hydrated peroxide of iron, which oxidizes and destroys the colouring matters, and, besides, absorbs the alkaline and earthy salts, and removes the small quantity of sulphate of lime remaining in the solution. (See *Am. Journ. of Pharm.*, Sept. 1862, p. 461.) M. Emile Monnier uses sulphurous acid as the bleaching agent. The acid is obtained by burning sulphur, and is conducted into a chamber which contains the sugar. About 4 parts of sulphur are required for 1000 of sugar. This undergoes no change under the action of the acid. When the operation is completed, the sugar is dissolved in water, and the sulphurous acid neutralized by a little lime. (*Chem. News*, May 15, 1868, p. 234.) M. Reynoso finds alumina the best defecating agent that he has employed; having succeeded by means of it in throwing down almost all impurities at the same time most adhesive and most hurtful. He adds the acid phosphate of alumina to the cane juice, and decomposes this with lime, by which the phosphate of lime is produced and alumina separated; and all these, with some lime in excess, cause the elimination of colouring and nitrogenous matters, so that there only remain in the

liquid some of the salts which normally accompany the sugar in the juice. (*Journ. de Pharm.*, 4e sér., ii. 232.)

The refining of brown sugar forms a distinct branch of business, and the methods pursued have undergone many improvements. By the original process, the sugar was boiled with lime-water, and clarified by heating it with bullocks' blood The clarified syrup was then strained through cloth filters, whereby it was rendered limpid. It was next transferred to a boiler, where it was subjected to ebullition until it was brought to a proper concentration; when it was allowed to cool in conical moulds, and to drain for the separation of the molasses. This last boiling required to be continued so long, that the action of the fire and air frequently decomposed the sugar to such an extent as to cause a loss of 25 per cent. in molasses. This disadvantage led to the abandonment of prolonged boiling; and now the sugar refiners boil the syrup in shallow boilers, which are suspended in such a way as to admit of their being emptied with the greatest quickness, without putting out the fire.

The process of refining was still further improved by Messrs. Philip Taylor and Howard. The former introduced the improvement of heating the syrup with great rapidity, by means of steam made to pass through a series of tubes traversing the boiler; and the latter devised the plan of causing the syrup to boil under a diminished pressure, created by a suction pump, set in motion by a steam engine, while it was heated by steam circulating round the boiler. In this way, the syrup was made to boil at a lower temperature, and with a diminished contact of the air; and the loss of cane sugar by its conversion into uncrystallizable sugar was in a great measure avoided.

After the syrup is sufficiently concentrated by any one of these methods, it is transferred to coolers, where it is agitated to cause it to granulate. In this state it is poured into unglazed earthenware moulds of a conical shape, with a hole in the apex, which is stopped with a paper plug. The moulds are placed, with the apex downwards, above stone-ware pots, intended to receive the uncrystallizable syrup. When the mass has completely concreted, the moulds are unstopped, to allow the coloured syrup to drain off. To separate the remains of this syrup, the operation called *claying* is performed. This consists in removing from the base of the loaf a layer of the sugar, about an inch thick, and replacing it with pure sugar in powder, which is covered with a mixture of pipe clay and water of about the consistence of cream. The water gradually leaves the clay, dissolves the pure sugar, and percolates the mass as a pure syrup, removing in its progress the coloured syrup. Sometimes the purification is performed without the use of clay, by allowing a saturated solution of pure sugar to percolate the loaf. When all the coloured syrup is removed, the loaf is taken out of the mould and placed in stoves to dry. It now constitutes *white* or *purified sugar*. The syrup which drains from the loaves contains a considerable quantity of cane sugar, and is used in subsequent operations. The syrups of lowest quality are employed in forming inferior white sugar, from which a syrup finally drains, containing so little cane sugar as not to repay the expense of extracting it. This constitutes *sugar-house molasses*. Good brown sugar, in the process of refining, yields about 70 per cent. of white sugar.

The application of animal charcoal to the refining of sugar is now very extensive, not less than 5000 tons of charred bones being used for this purpose annually in the Clyde refineries, in Scotland. For valuable practical remarks on the use of this agent in the purification of sugar, the reader is referred to a paper by Dr. Wallace in the *Transactions of the Philosophical Society of Glasgow*, copied in the *American Journal of Pharmacy* (Sept. 1868, p. 425).

Commercial History. Cane sugar was known to the ancients. It was originally obtained from India, where it was extracted from the sugar cane. About the period of the Crusades, the Venetians brought it to Europe; but, at that time, it was so scarce and costly as to be used exclusively as a medicine. Upon the discovery of the Cape of Good Hope and the maritime route to the East Indies, the commerce in sugar passed into the hands of the Portuguese. Sub-

sequently, the cultivation of the cane extended to Arabia, Egypt, Sicily, Spain, and the Canaries, and finally, upon the discovery of the new world, to America, where it was pursued with the greatest success, and continues to be so. In America it is produced most abundantly in the West Indies, which supply the greater part of the consumption of Europe, little comparatively being taken thither from Brazil or the East Indies. The consumption of the United States, before the late war, was more than half supplied by Louisiana and some of the neighbouring States. The crop of sugar of Louisiana, in 1847, was estimated at 240,000 hogsheads; in 1853, at 322,000. The crop of Cuba for the latter year is supposed to have reached 600,000 hogsheads. Latterly, our planters have introduced into Louisiana the variety of cane called the Otaheitan cane, which is hardier and more productive than the common cane, and better suited to the climate of our Southern States.

Properties. Sugar, in a pure state, is a solid of a peculiar grateful taste, permanent in the air, phosphorescent by friction, and of the sp. gr. 1·6. It dissolves readily in half its weight of cold water, and to almost an unlimited extent in boiling water. The solution, when thick and ropy, is called *syrup*. An aqueous solution of sugar, kept in a warm place, has the property of corroding iron, partially immersed in it, just above the line where the surface of the liquid touches the metal; and the solution itself becomes impregnated with protoxide of iron, and of a deep red-brown colour. A similar effect is produced on lead; but zinc and copper are but slightly acted on. (Dr. J. H. Gladstone, *Annals of Pharmacy*, iii. 208.) A solution of sugar possesses the property also of dissolving a large quantity of hydrate of lime, forming a compound, called *syrup of lime*. When a concentrated syrup is gently heated, and spirit added to it, the liquid, on cooling, forms white semi-transparent crystals of hydrated sugar, having the shape of oblique four-sided prisms, and called *sugar-candy*. Sugar is nearly insoluble in absolute alcohol, but dissolves in four times its weight of boiling alcohol, of the sp. gr. 0·83. When heated to 365°, it melts into a viscid, colourless liquid, which, on being suddenly cooled, forms a transparent amorphous mass, called *barley sugar*. At a higher temperature (between 400° and 420°) it loses two eqs. of water, and is converted into a black porous mass, having a high lustre, called *caramel*.* At a still higher heat it yields combustible gases, carbonic acid, empyreumatic oil, and acetic acid; and there remains one-fourth of its weight of charcoal, which burns without residue. Sugar renders the fixed and volatile oils to a certain extent miscible with water, and forms with the latter an imperfect combination, called in pharmacy *oleo-saccharum*. When in solution, it is not precipitated by subacetate of lead, a negative property which distinguishes it from most other organic principles.

Tests. Cane sugar may be distinguished from grape sugar by Trommer's test, which consists in the use of sulphate of copper and caustic potassa. If a solution of cane sugar be mixed with a solution of sulphate of copper, and potassa be added in excess, a deep-blue liquid is obtained, which, on being heated, lets fall, after a time, a little red powder. A solution of grape sugar, similarly treated, yields, by heat, a copious greenish precipitate, which rapidly changes to scarlet, and eventually to dark-red. Prof. Böttger finds that, when a liquid containing grape sugar is boiled with carbonate of soda and some basic nitrate of bismuth, a gray coloration or blackening of reduced bismuth is produced. Cane sugar, similarly treated, has no effect on the test. Dr. Donaldson's test for sugar in the *animal fluids* is formed of 5 parts of carbonate of soda, 5 of caustic potassa, 6 of bitartrate of potassa, 4 of sulphate of copper, and 32 of distilled water. A few drops of this solution, being added to an animal fluid,

* A colouring substance called *caramel brown* is now largely manufactured from sugar by decomposing it by means of heat carefully applied, with manipulations calculated to ensure a uniform product. It is in the form either of a stiff paste, in which it is used for colouring leather, or in that of a syrup, for colouring liquids. For the precise mode of preparation, see a paper by Mr. Thos. Sherlock in the *Chemical News* for June 7, 1867 (p. 282). It may be made either from cane sugar, molasses, or glucose. (*Note to the thirteenth edition.*)

and the mixture heated over a spirit-lamp, a yellowish-green colour is developed, if sugar be present. J. Horsley's test for sugar in diabetic urine is an alkaline solution of chromate of potassa, a few drops of which, boiled with the urine, will make it assume a deep sap-green colour. M. J. Nicklés points out, in the bichloride of carbon, obtained by decomposing sulphide of carbon by chlorine and aqueous vapour, a new test for distinguishing glucose and cane sugar. This test mixed with cane sugar in a glass tube, kept for some time near 212°, causes a darkening of the sugar, gradually increasing till it becomes black. Glucose undergoes no such change. (*Journ. de Pharm.*, 4e sér., iii. 119.)

Action of Acids and Alkalies, &c. The mineral acids act differently on cane sugar, according as they are concentrated or dilute. Strong nitric acid, with the assistance of heat, converts it into oxalic acid (See *Oxalic Acid* in *Part* III.) The same acid, when weak, converts it into *saccharic acid*, confounded by Scheele with malic acid. Concentrated muriatic or sulphuric acid chars it. Diluted muriatic acid, when boiled with cane sugar, converts it into a solid, brown, gelatinous mass. Weak sulphuric acid, by a prolonged action at a high temperature, converts cane sugar, first into uncrystallizable sugar, afterwards into grape sugar, and finally into two substances, analogous to ulmin and ulmic acid, called *sacchulmin* and *sacchulmic acid*. Vegetable acids are supposed to act in a similar way. Maumené has found that cane sugar undergoes the change into uncrystallizable sugar when kept for a long time in aqueous solution, as well as when heated with acids. When the boiling with acids is prolonged for several days in open vessels, oxygen is absorbed, and, besides sacchulmin and sacchulmic acid, formic acid is generated. Soubeiran admits the change of the uncrystallizable into grape sugar, but attributes it to a molecular transformation of the sugar, independently of the action of the acid; as, according to his observation, the conversion takes place only after rest. In confirmation of his views, this chemist states that he found the same changes to be produced by boiling sugar with water alone.

Cane sugar unites with the alkalies and some of the alkaline earths, forming definite combinations which render the sugar less liable to change. It also unites with protoxide of lead. Boiled for a long time with aqueous solutions of potassa, lime, or baryta, the liquid becomes brown, formic acid is produced, and two new acids are generated; one brown or black and insoluble in water, called *melassic acid*, the other colourless and very soluble, named *glucic acid*. Alkalies and the alkaline earths are said to lessen the rotatory power of sugar in relation to polarized light; but the sugar recovers its original power when the alkali is saturated. (*Journ. de Pharm.*, 4e sér., iv. 314.)

The account above given of the action of acids and alkalies on cane sugar explains the way in which lime acts in the manufacture and refining of sugar. The acids, naturally existing in the saccharine juice, have the effect of converting the cane sugar into uncrystallizable sugar, by which a loss of the former is sustained. The lime, by neutralizing these acids, prevents that result. An excess of lime, however, must be carefully avoided; as it injures the product of cane sugar both in quantity and quality. The change in sugar which precedes fermentation, namely, the conversion of cane sugar into the uncrystallizable kind, points to the necessity of operating on the juice before that process sets in; and hence the advantage of grinding canes immediately after they are cut, and boiling the juice with the least possible delay.

The following is a description of the several forms of sugar in common use, including the two officinal varieties.

Purified or *white sugar*, as obtained on a large scale, is in concrete, somewhat porous masses, called loaves, consisting of an aggregate of small crystalline grains. When carefully refined, it is brittle and pulverulent, perfectly white, inodorous, and possessed of the pure saccharine taste. Cane sugar is sometimes adulterated with starch sugar, which may be detected by adding to a concentrated solution of the suspected sugar, first a small portion of fused potassa, and afterwards, at the boiling temperature, a few drops of nitrate of cobalt This

test, if the cane sugar be pure, will produce a violet-blue precipitate, a reaction prevented by the presence of a small proportion of starch sugar. (*Dr. G Reich.*)* Indigo is said to be sometimes added by refiners to the purified sugar to give increased brilliance to its whiteness. In such instances, when the sugar is used in preparing syrup, the foam which forms on the surface assumes a blue colour, on exposure to the air. (*Journ. de Pharm.*, 4e sér., ii. 128.)

Unpurified or *brown sugar* is in the form of a coarse powder, more or less moist and sticky, consisting of shining crystalline grains intermixed with lumps, having an orange-yellow colour more or less deep, a sweet, cloying taste, and heavy peculiar smell. It varies very much in quality. The best sort is nearly dry, in large sparkling grains of a clear yellow colour, and possesses much less smell than the inferior kinds. It consists of cane sugar, associated, according to Messrs. Alexander and Morfit, with variable quantities of hygroscopic moisture, uncrystallizable sugar, gum, albumen, extractive, saline matter, and insoluble organic and inorganic substances. (*Chem. Gaz.*, April 15, 1858, p. 153.) Among the inorganic substances is a small proportion of lime. By keeping it becomes soft and gummy, and less sweet, a change attributed to the lime.

Molasses is of two kinds, the West India and sugar-house. *West India molasses* is a black ropy liquid, of a peculiar odour, and sweet empyreumatic taste. When mixed with water and with the skimmings of the vessels used in the manufacture of sugar, it forms a liquor, which, when fermented and distilled, yields rum. *Sugar-house molasses* has the same general appearance as the West India, but is thicker, and has a different flavour. Its sp. gr. is about 1·4, and it contains about 75 per cent. of solid matter. Both kinds of molasses consist of uncrystallizable sugar, more or less cane sugar which has escaped separation in the process of manufacture or refining, and gummy and colouring matter. When the molasses from cane sugar is treated with a boiling, concentrated solution of bichromate of potassa, and boiled, a violent reaction takes place, and the liquid becomes green; but if it be adulterated with only an eighth of starch sugar molasses, the reaction is prevented, and the colour is not changed. (*Dr. G. Reich.*)

Composition. The following formulas express the composition of the different varieties of sugar, so far as known. *Cane sugar*, $C_{12}H_{11}O_{11}$. Of the same composition are *mycose*, *melitose*, *melizotose*, and *trehalose*, which, as before stated, constitute a group closely analogous to cane sugar, though differing in some of their properties. The formula of *glucose* or grape sugar is $C_{12}H_{12}O_{12}$; and *uncrystallizable sugar*, also named variously *chulariose*, *inverse sugar*, and *levulose*, which is characterized by a left rotatory power in reference to polarized light, has the same composition. With these also agree *sorbite* and *inosite*. The formula of *mannite* and of *dulcite* (dulcin or dulcose) is $C_{12}H_{14}O_{12}$.

Med. and Pharm. Uses, &c. The uses of sugar as an aliment and condiment are numerous. It is nutritious, but not capable of supporting life when taken

* *Estimation of Cane Sugar and Glucose.* The aqueous solution of a mixture of ferridcyanide of potassium (red prussiate of potassa), with half its weight of hydrate of potassa, has no chemical action on a solution of cane sugar, cold or hot, yet communicates to it, even in very small proportion, a decided and persistent yellowness. With a solution of glucose or grape sugar it loses its colour slowly if cold, and more rapidly as the temperature is raised. If a few drops be added to a solution of glucose at 140°, the yellow colour at first produced very soon disappears, and, if the heat be raised to 170°, is immediately destroyed. If now the addition continue to be made, the colour will continue to disappear so long as any of the glucose remains. By experiment it was ascertained that 10·98 grammes of the ferridcyanide were sufficient to destroy 1 gramme of sugar converted by muriatic acid into glucose. A normal solution may be made by mixing 10·98 grammes of the ferridcyanide with 5·50 grammes of hydrate of potassa and dissolving this in 100 cubic centimetres of water. Suppose a mixture of cane sugar and glucose to be tested. Dissolve 1 gramme of it in 40 cubic centimetres of water, heat to 160° F., and add one-tenth of the normal solution. If there is much glucose the colour disappears; in which case the solution is to be added by cubic centimetres till the colour ceases to disappear. As many centimetres of the normal liquid as are used, so many hundredths of the 10·98 grammes of the ferridcyanide, and of course of one gramme of glucose, will have been consumed, indicating that quantity of the latter in the mixture. (Gentele, *Journ. de Pharm.*, Mars, 1860, p. 208.)—*Note to the twelfth edition.*

exclusively as aliment, on account of the absence of nitrogen in its composition. It is a powerful antiseptic, and is used for preserving meat and fish; for which purpose it possesses the advantage of acting in a much less quantity than is requisite of common salt, and of not altering the taste, or impairing the nutritious qualities of the aliment. Prof. Marcband has ascertained that a solution of sugar has no action on the teeth out of the body. It may hence be inferred that the popular notion that sugar is injurious to the teeth is unfounded.

The medical properties of *sugar* are those of a demulcent; and as such it is much used in catarrhal affections, in the form of candy, syrup, &c. According to M. Provençal, it acts as a powerful antaphrodisiac, when taken in the quantity of a pound or more daily, dissolved in a quart of cold water. For an account of the supposed therapeutic power of the vapour of boiling cane juice, in bronchitis and incipient consumption, applied by living in a sugar-house, the reader is referred to the papers of Dr. S. A. Cartwright, of New Orleans, contained in the 47th and 51st volumes of the *Boston Med. and Surg. Journal.* In pharmacy sugar is employed to render oils miscible with water, to cover the taste of medicines, to give them consistency, to preserve them from change, and to protect certain ferruginous preparations from oxidation. Accordingly it enters into the composition of the compound infusion of roses, of several mixtures, pills, and powders, of many fluid extracts, syrups, confections, and of all the troches. *Molasses* is used for forming pills, for which it is well fitted, preserving them soft and free from mouldiness, on account of its retentiveness of moisture and antiseptic qualities.

The influence of sugar in preventing changes in organic substances may be ascribed to an extraordinary osmotic power in its solutions, by which infusoria and all other of the lower forms of life, to which fermentative processes are now generally ascribed, are almost instantly destroyed; the organism collapsing through the rapid exosmose of its fluids into the saccharine medium. All the different kinds of sugar susceptible of the alcoholic fermentation have this power. (Dr. Louis Mandl, *Archives Gén. de Méd.*, 5e sér., xvi. 49, Juillet, 1860.)

SACCHARUM LACTIS. *U. S., Br.*

Sugar of Milk.

A crystalline substance obtained from whey. *U. S.* $O_{24}H_{24}O_{24}$. Crystallized sugar obtained from the whey of milk by evaporation. *Br.*

Lactose; Sucre de lait, *Fr.;* Milchzucker, *Germ.*

Sugar of milk, or *lactin*, is found only in milk, of which it forms about 5 per cent. (*Boussingault.*) It is manufactured largely in Switzerland and the Bavarian Alps, as an article of food and for medicinal purposes. In preparing it, milk is first coagulated by the addition of a little dilute sulphuric acid, and the resulting *whey* is evaporated to a syrupy consistence, and set aside for several weeks, in a cool place, to crystallize. The crystals, which constitute the sugar of milk, are then decolorized by animal charcoal and repeated crystallizations.*

Sugar of milk is a hard, somewhat gritty, white substance, crystallized in four-sided prisms, and possessing a slightly sweet taste. In commerce it sometimes occurs in cylindrical masses, in the axis of which is a cord, around which the crystals have been deposited. It dissolves slowly in six parts of cold and three of boiling water, without forming a syrup. It is insoluble in ether, and but slightly soluble in alcohol. Its sp. gr. is 1·54. It is not susceptible of the vinous fermentation by the direct influence of yeast; but, after the action of dilute acids, which first convert it into grape sugar, it is capable of furnishing

* For a method of estimating the proportion of lactin in milk, see an article by M. Poggiale in the *Journ. de Pharm.*, Août, 1858, p. 130.

a spirituous liquor. It is well known that both mares' and cows' milk, after becoming sour, is capable of forming an intoxicating drink by fermentation. By the action of nitric acid, sugar of milk is converted into mucic (saccholactic) acid. When anhydrous it consists of $C_{12}H_{11}O_{11}$; when crystallized, of $C_{12}H_{11}O_{11}+HO$. (*Staedeler and Krause.*) These formulas make anhydrous sugar of milk isomeric with cane sugar, and the crystallized with anhydrous grape sugar. Fudakowski has ascertained that sugar of milk, when treated with weak sulphuric acid, is divided into two peculiar saccharine bodies; one crystallizable, and previously noticed by Pasteur (*Comptes Rendus*, xlii. 347), the other is new. The latter is more soluble in alcohol than the former, has a sweeter taste, ferments more easily, crystallizes in prisms, while the former is tabular, and has a different polarizing action. (*Journ. de Pharm.*, 4e sér., v. 479; from *Zeitschr. für Chem.*, 1867, p. 32.)

Sugar of milk has been proposed by Dr. Turnbull, of England, as a non-nitrogenous article of diet, in consumption and other pulmonary diseases. Dr. Ruschenberger used it with good effect as nourishment in a case of extreme irritability of stomach, following profuse loss of blood from menorrhagia (*Trans. of the Philad. Col. of Phys.*, ii. 48.) B.

SAGO. *U. S.*

Sago.

The prepared fecula of the pith of Sagus Rumphii, and of other species of Sagus. *U. S.*

Sagou, *Fr.;* Sago, *Germ., Ital.;* Sagu, *Span.*

Numerous trees, inhabiting the islands and coasts of the Indian Ocean, contain a farinaceous pith, which is applied to the purposes of nutriment by the natives. Such are *Sagus Rumphii*, *Sagus lævis*, *Sagus Ruffia*, *Saguerus Rumphii*, and *Phœnix farinifera*, belonging to the family of *palms;* and *Cycas circinalis*, *Cycas revoluta*, and *Zamia lanuginosa*, belonging to the *Cycadaceæ* Of these *Sagus Rumphii*, *Sagus lævis*, and *Saguerus Rumphii* probably contribute to furnish the sago of commerce. Crawford, in his History of the Indian Archipelago, states that it is derived exclusively from *Metroxylon Sagu*, identical with *Sagus Rumphii;* but Roxburgh ascribes the granulated sago to *S lævis*, and one of the finest kinds is said by Dr. Hamilton to be produced by the *Saguerus Rumphii* of Roxburgh. The farinaceous product of the different species of Cycas, sometimes called *Japan sago*, does not enter into general commerce.

Sagus. *Sex. Syst.* Monœcia Hexandria. — *Nat. Ord.* Palmaceæ.

Gen. Ch. Common spathe one-valved. *Spadix* branched. Male. *Calyx* three-leaved. *Corolla* none. *Filaments* dilated. Female. *Calyx* three-leaved, with two of the leaflets bifid. *Corolla* none. *Style* very short. *Stigma* simple. *Nut* tessellated-imbricated, one-seeded. *Willd.*

Sagus Rumphii. Willd. *Sp. Plant.* iv. 404; Carson, *Illust. of Med. Bot.* ii. 44, pl. 88. The *sago palm* is one of the smallest trees of its family. Its extreme height seldom exceeds thirty feet. The trunk is proportionably very thick, quite erect, cylindrical, covered with the remains of the old leafstalks, and surrounded by a beautiful crown of foliage, consisting of numerous, very large, pinnate leaves, extending in all directions from the summit, and curving gracefully downwards. From the basis of the leaves proceed long, divided and subdivided flower and fruit-bearing spadices, having smooth branches. The fruit is a roundish nut, covered with a checkered imbricated coat, and containing a single seed.

The tree is a native of the East India islands, growing in the Peninsula of Malacca, Sumatra, Borneo, Celebes, the Moluccas, and a part of New Guinea. It flourishes best in low and moist situations. Before attaining maturity, the stem consists of a shell, usually about two inches thick, filled with an enormous volume of spongy medullary matter like that of elder. This is gradually absorbed after the appearance of fruit, and the stem ultimately becomes hollow. The greatest age of the tree is not more than thirty years. Large quantities of a

kind of sugar called jaggary are procured from its juice. At the proper period of its growth, when the medullary matter is fully developed, and has not yet begun to diminish, the tree is felled, and the trunk cut into billets six or seven feet long, which are split in order to facilitate the extraction of the pith. This is obtained in the state of a coarse powder, which is mixed with water in a trough, having a sieve at the end. The water, loaded with farina, passes through the sieve, and is received in convenient vessels, where it is allowed to stand till the insoluble matter has subsided. It is then strained off; and the farina which is left may be dried into a kind of meal, or moulded into whatever shape may be desired. For the consumption of the natives it is usually formed into cakes of various sizes, which are dried, and extensively sold in the islands. The commercial sago is prepared by forming the meal into a paste with water, and rubbing it into grains. It is produced in the greatest abundance in the Moluccas, but of the finest quality on the eastern coast of Sumatra. The Chinese of Malacca refine it so as to give the grains a fine pearly lustre. Malcolm states that it is also refined in large quantities at Singapore. In this state it is called *pearl sago*, and is in great repute. It is said that not less than five or six hundred pounds of sago are procured from a single tree. (*Crawford.*)

Pearl sago is that which is now generally used. It is in small grains, about the size of a pin's head, hard, whitish, of a light-brown colour, in some instances translucent, inodorous, and with little taste. It may be rendered perfectly white by a solution of chloride of lime. *Common sago* is in larger and browner grains, of more unequal size, of a duller aspect, and frequently mixed with more or less of a dirty-looking powder.

Sago meal is imported into England from the East Indies; but we have met with none in the markets of this country. It is in the form of a fine amylaceous powder, of a whitish colour, with a yellowish or reddish tint, and of a faint but somewhat musty odour.

Common sago is insoluble in cold water, but by long boiling unites with that liquid, becoming at first soft and transparent, and ultimately forming a gelatinous solution. Pearl sago is partially dissolved by cold water, probably owing to heat used in its preparation. Chemically considered, it has the characters of starch. Under the microscope the granules of sago meal appear oval or ovate, and often truncated so as to be more or less mullar-shaped. Many of them are broken, and in most the surface is irregular or tuberculated. They exhibit upon their surface concentric rings, which are much less distinct than in potato starch. The hilum is circular when perfect, and cracks either with a single slit or a cross, or in a stellate manner. The granules of pearl sago are of the same form, but are all ruptured, and exhibit only indistinct traces of the annular lines, having been altered in the process employed in preparing them. Those of common sago are very similar to the particles of sago meal, except that they are perhaps rather less regular and more broken. (*Pereira.*)

Potato starch is sometimes prepared in Europe so as to resemble bleached pearl sago, for which it is sold. But, when examined under the microscope, it exhibits larger granules, which are also more regularly oval or ovate, smoother, less broken, and more distinctly marked with the annular rugæ than those of sago; and the hilum often cracks with two slightly diverging slits.

Sago is used exclusively as an article of diet. Being nutritive, easily digestible, and wholly destitute of irritating properties, it is frequently employed in febrile cases, and in convalescence from acute disorders, in the place of richer and less innocent food. It is given in the liquid state, and in its preparation care should be taken to boil it long in water, and stir it diligently, in order that the grains may be thoroughly dissolved. Should any portion remain undissolved, it should be separated by straining; as it might offend a delicate stomach. A tablespoonful to the pint of water is sufficient for ordinary purposes. The solution may be seasoned with sugar and nutmeg or other spice, and with wine, when these are not contraindicated. W.

SALIX. *U. S. Secondary.*

Willow.

The bark of Salix alba. *U. S.*

Ecorce de saule, *Fr.;* Weidenrinde, *Germ.;* Corteccia di salcio, *Ital.;* Corteza de sauce, *Span.*

Salix. *Sex. Syst.* Dicœcia Diandria. — *Nat Ord.* Salicaceæ.

Gen. Ch. Male. *Amentum* cylindrical. *Calyx* a scale. *Corolla* none. *Glands* of the base nectariferous. Female. *Amentum* cylindrical. *Calyx* a scale. *Corolla* none. *Style* two-cleft. *Capsule* one-celled, two-valved. *Seeds* downy.

This is an extensive genus, comprising, according to Nuttall, not less than one hundred and thirty species, which, with very few exceptions, are natives of Europe, and of the northern and temperate parts of North America. Though most of them are probably possessed of similar medical properties, only one is recognised as officinal; viz., *S. alba*, which has been introduced into this country. *S. Russelliana*, which has also been introduced from Europe, is said by Sir James Smith to be the most valuable species. *S. purpurea*, a European species, is said by Lindley to be the most bitter, and *S. pentandra* is preferred by Nees von Esenbeck. Many native species are in all probability equally active with the foreign; but they have not been sufficiently tried in regular practice to admit of a positive decision. The younger Michaux speaks of the root of *S. nigra* or *black willow*, as a strong bitter, used in the country for the prevention and cure of intermittents In consequence of the pliability of the young branches, the willow is well adapted for the manufacture of baskets and other kinds of wicker-work; and several species, native and introduced, are employed for this purpose in the United States *S. Babylonica*, or *weeping willow*, is a favourite ornamental tree. The degree of bitterness in the bark is probably the best criterion of the value of the several species.

Salix alba. Willd. *Sp. Plant.* iv. 710; Smith, *Flor. Brit.* 1071. The common European or white willow is twenty-five or thirty feet in height, with numerous round spreading branches, the younger of which are silky. The bark of the trunk is cracked and brown, that of the smaller branches smooth and greenish. The leaves are alternate, upon short petioles, lanceolate, pointed, acutely serrate with the lower serratures glandular, pubescent on both sides, and silky beneath. There are no stipules. The flowers appear at the same time with the leaves. The *amenta* are terminal, cylindrical, and elongated, with elliptical-lanceolate, brown, pubescent scales. The stamens are two in number, yellow, and somewhat longer than the scales; the style is short; the stigmas two-parted and thick. The capsule is nearly sessile, ovate, and smooth. The white willow is now very common in this country. It flowers in April and May; and the bark is easily separable throughout the summer.

That obtained from the branches rolls up when dried into the form of a quill, has a brown epidermis, is flexible, fibrous, and of difficult pulverization. Willow bark has a feebly aromatic odour, and a peculiar bitter astringent taste. It yields its active properties to water, with which it forms a reddish-brown decoction. Pelletier and Caventou found, among its ingredients, tannin, resin, a bitter yellow colouring matter, a green fatty matter, gum, wax, lignin, and an organic acid combined with magnesia. The proportion of tannin is so considerable that the bark has been used for tanning leather. A crystalline principle has also been obtained from it, which, having the medical virtues of the willow, has received the name of *salicin.* When pure, it is in white, shining, slender crystals, inodorous, but very bitter, with the peculiar flavour of the bark. It is soluble in cold water, much more so in boiling water, soluble in alcohol, and insoluble in ether and oil of turpentine. It neutralizes neither acids nor salifiable bases, and is not precipitated by any reagent. Concentrated sulphuric acid decomposes it, receiving from it an intense and permanent bright-red colour, and producing a new compound called *rutulin.* It ranks with the glucosides, being resolved by boiling with dilute muriatic and sulphuric acids into grape sugar, saligenin, and

a white, tasteless, insoluble resinous substance named *saliretin*. *Saligenin* is a colourless, crystallizable substance, fusible and volatilizable, soluble in water, alcohol, and ether, and if heated above 212°, giving off aqueous vapour and salicylous acid. (*Gmelin's Handbook.*) Nitric acid produces with salicin at first two principles called respectively helicin and helicoidin, and afterwards picric and oxalic acids. (*Journ. de Pharm.*, xxx. 43.) Distilled with bichromate of potassa and sulphuric acid, it yields, among other products, a volatile oleaginous liquid, identical with one of the components of oil of spiræa, and, from its acid properties, denominated *salicylous acid*. This is considered by Dumas as consisting of a peculiar compound radical, called *salicyl*, and hydrogen. The formula of salicyl is $C_{14}H_5O_4$. The discovery of salicin is claimed by Buchner, of Germany, and Fontana and Rigatelli, of Italy; but M. Leroux, of France, deserves the credit of having first accurately investigated its properties. Braconnot procured it by adding subacetate of lead to a decoction of the bark, precipitating the excess of lead by sulphuric acid, evaporating the colourless liquid which remained, adding near the end of the process a little animal charcoal previously washed, and filtering the liquor while hot. Upon cooling it deposited the salicin in a crystalline form. (*Journ. de Chimie Médicale*, Jan. 1831.) The following is the process of Merck. A boiling concentrated decoction of the bark is treated with litharge until it becomes nearly colourless. Gum, tannin, and extractive matter, which would impede the crystallization of the salicin, are thus removed from the liquid; while a portion of the oxide is dissolved in union probably with the salicin. To separate this portion of oxide, sulphuric acid is first added and then sulphuret of barium, and the liquor is filtered and evaporated. Salicin is deposited, and may be purified by repeated solution and crystallization (*Turner's Chemistry.*) Erdmann has given another process. Sixteen ounces of the bark are macerated for twenty-four hours in four quarts of water mixed with two ounces of lime, and the whole is then boiled for half an hour. The process is repeated with the residue. The decoctions having been mixed, and allowed to become clear by subsidence, the liquor is poured off, concentrated to a quart, then digested with eight ounces of ivory-black, filtered, and evaporated to dryness. The extract is exhausted by spirit containing 28 per cent. of alcohol, and the tincture evaporated so that the salicin may crystallize. This is purified by again dissolving, treating with ivory-black, and crystallizing. Merck obtained 251 grains from 16 ounces of the bark and young twigs of *Salix helix*, and Erdmann 300 grains from the same quantity of the bark of *Salix pentandra*. It may probably be obtained from any of the willow barks having a bitter taste. Braconnot procured it from various species of Populus, particularly *P. tremula* or European aspen.

Medical Properties and Uses. The bark of the willow is tonic and astringent, and has been employed as a substitute for Peruvian bark, particularly in intermittent fever. It has attracted much attention from the asserted efficacy of salicin in the cure of this complaint. There seems to be no room to doubt, from the testimony of numerous practitioners in France, Italy, and Germany, that this principle has the property of arresting intermittents; though the ascription to it of equal efficacy with sulphate of quinia was certainly incorrect. It is asserted that, when freely taken, it is passed by the kidneys, and may be separated by alcohol from the residue left on the evaporation of the urine. The bark may be employed in substance or decoction, in the same doses and with the same mode of preparation as cinchona. The dose of salicin is from two to eight grains, to be so repeated that from twenty to forty grains may be taken daily, or in the interval between the paroxysms of an intermittent. Magendie has seen fevers cut short in one day by three doses of six grains each. The decoction of willow has been found beneficial as an external application to foul and indolent ulcers.

Salicylous acid and the salicylites have been used in medicine by M. Demartis, of France, and have been found to exert a direct sedative influence on the economy without any previous excitement, which renders them useful in inflammatory and febrile affections. He gave the salicylite of potassa in the dose of about four grains. (*Ann. de Thérap.*, 1854, p. 77.) W.

Salvia. *Sex. Syst.* Diandria Monogynia. — *Nat. Ord.* Lamiaceæ or Labiatæ. *Gen. Ch. Corolla* unequal. *Filaments* affixed transversely to a pedicel. *Willd.*

Salvia officinalis. Willd. *Sp. Plant.* i. 129; Woodv. *Med. Bot.* p. 352, t. 127. Common garden sage is a perennial plant, about two feet high, with a quadrangular, pubescent, branching, shrubby stem, furnished with opposite, petiolate, ovate-lanceolate, crenulate, wrinkled leaves, of a grayish-green colour, sometimes tinged with red or purple. The flowers are blue, variegated with white and purple; and are disposed on long terminal spikes, in distant whorls, each composed of a few flowers, and accompanied with ovate, acute, deciduous bractes. The calyx is tubular and striated, with two lips, of which the upper has three acute teeth, the under two. The corolla is tubular, bilabiate, ringent, with the upper lip concave, and the lower divided into three rounded lobes, of which the middle is the largest. The filaments are supported upon short pedicels, to which they are affixed transversely at the middle.

Sage grows spontaneously in the south of Europe, and is cultivated abundantly in our gardens. There are several varieties, differing in the size and colour of their flowers, but all possessing the same medical properties. The flowering period is in June, at which time the plant should be cut, and dried in a shady place. The leaves are the officinal portion.

Both these and the flowering summits have a strong fragrant odour, and a warm, bitterish, aromatic, somewhat astringent taste. They abound in a volatile oil, which may be obtained separate by distillation with water, and contains a considerable proportion of camphor. Sulphate of iron strikes a black colour with their infusion.

Medical Properties and Uses. Sage unites a slight degree of tonic power and astringency with aromatic properties. By the ancients it was highly esteemed; but it is at present little used internally, except as a condiment. In the state of infusion it may be given in debility of the stomach with flatulence, and is said to have been useful in checking the sweats of hectic fever. But its most useful application is as a gargle in inflammation of the throat, and relaxation of the uvula. For this purpose it is usually employed in infusion, with honey and alum, or vinegar. The dose of the powdered leaves is from twenty to thirty grains. The infusion is prepared by macerating an ounce of the leaves in a pint of boiling water, of which two fluidounces may be administered at once. When intended merely as a pleasant drink in febrile complaints, or to allay nausea, the maceration should continue but a very short time, so that all the bitterness of the leaves may not be extracted.

Two other species of Salvia—*S. pratensis* and *S. Sclarea*—are ranked among officinal plants in Europe. The latter, which is commonly called *clarry*, has been introduced into our gardens. Their medical properties are essentially the same as those of the common sage; but they are less agreeable, and are not much used. In Europe, the leaves of *S. Sclarea* are said to be introduced into wine in order to impart to it a muscadel taste.

Sureau, *Fr.;* Hollunder, *Germ.;* Sambuco, *Ital.;* Sauco, *Span.*

SAMBUCUS. *Sex. Syst.* Pentandria Trigynia. — *Nat. Ord.* Caprifoliaceæ. *Gen. Ch. Calyx* five-parted. *Corolla* five-cleft. *Berry* three-seeded. *Willd.*

Sambucus Canadensis. Willd. *Sp. Plant.* i. 1494. Our indigenous *common elder* is a shrub from six to ten feet high, with a branching stem, covered with a rough gray bark, and containing a large spongy pith. The small branches and leafstalks are very smooth. The leaves are opposite, pinnate, sometimes bipinnate, and composed usually of three or four pairs of oblong-oval, acuminate, smooth, shining, deep-green leaflets, the midribs of which are somewhat pubescent. The flowers are small, white, and disposed in loose cymes, having about five divisions. The berries are small, globular, and deep-purple when ripe.

The shrub grows in low moist grounds, along fences, and on the borders of small streams, in all parts of the United States, from Canada to the Carolinas, and westward as far as Texas. It flowers from May to July, and ripens its fruit early in autumn. The flowers, which are officinal, have an aromatic, though rather heavy odour. The berries as well as other parts of the plant are employed, in domestic practice, for the same purposes as the corresponding parts of the European elder, to which this species bears a close affinity.

Sambucus nigra. Willd. *Sp. Plant.* i. 1495; Woodv. *Med. Bot.* p. 596, t. 211. The common elder of Europe differs from the American most obviously in its size, which approaches to that of a small tree. The stem is much branched towards the top, and has a rough whitish bark. The leaves are pinnate, consisting usually of five oval, pointed, serrate leaflets, four of which are in opposite pairs, and the fifth terminal. The flowers are small, whitish, and in five-parted cymes. The berries are globular, and blackish-purple when ripe. A fungus growing on this plant, called *fungus sambuci*, had a century since some reputation in Europe as a refrigerant in ophthalmia, and has recently been revived as a remedy in the same disease. It was ascertained by Steckel, an apothecary of N. Germany, to have an extraordinary power, when immersed in water, of absorbing that fluid, so as to increase its weight sevenfold; and, if long immersed, it is capable of taking up from 9 to 12 times its weight. It has, besides, the property of retaining the absorbed water very adhesively. This property adapts it admirably to the local treatment of conjunctivitis; and on trial it has been found successful where the ordinary applications have proved fruitless. (*Neues Repert.*, xiii. 476, A.D. 1864.)

The *flowers* have a peculiar sweetish odour, which is strong in their recent state, but becomes feeble by drying. Their taste is bitterish. They yield their active properties to water by infusion, and when distilled give over a small proportion of volatile oil, which on cooling assumes a butyraceous consistence. Water distilled from them contains an appreciable portion of ammonia. The *berries* are nearly inodorous, but have a sweetish, acidulous taste, dependent on the presence of saccharine matter and malic acid. Their expressed juice is susceptible of fermentation, and forms a vinous liquid used in the north of Europe It is coloured violet by alkalies, and bright red by acids; and the colouring matter is precipitated blue by acetate of lead. The *inner bark* is without smell. Its taste is at first sweetish, afterwards slightly bitter, acrid, and nauseous. Both water and alcohol extract its virtues, which are said to reside especially in the green layer between the liber and epidermis. According to Simon, the active principle of the inner bark of the root is a soft resin, which may be obtained by exhausting the powdered bark with alcohol, filtering the tincture, evaporating to the consistence of syrup, then adding ether, which dissolves the active matter, and finally evaporating to the consistence of a thick extract. Of this, twenty grains produce brisk vomiting and purging. (*Annal. der Pharm.*, xxxi. 262.) The bark, analyzed by Kramer, yielded an acid called by him *viburnic acid*, which has proved to be the *valerianic*, traces of volatile oil, albumen, resin, an acid sulphurous fat, wax, chlorophyll, tannic acid, grape sugar, gum, extractive, starch, pectin, and various alkaline and earthy salts. (*Chem. Gaz.*, May, 1846; from *Archiv. der Pharm.*)

Medical Properties and Uses. The flowers are gently excitant and sudorific,

but are seldom used, except externally as a discutient, in the form of poultice, fomentation, or ointment. The berries are diaphoretic and aperient; and their inspissated juice has enjoyed some reputation as a remedy in rheumatic, gouty, eruptive, and syphilitic affections. Its dose as an alterative diaphoretic is one or two drachms, as a laxative half an ounce or more. The inner bark is a hydragogue cathartic, and in large doses emetic. It has been employed in dropsy, epilepsy, and as an alterative in various chronic diseases. An ounce may be boiled with two pints of water to a pint, and four fluidounces of the decoction given for a dose. It is also used in vinous infusion. The leaves are not without activity, and the young leaf-buds are said to be a violent and even unsafe purgative. The juice of the root has been highly recommended in dropsy as a hydragogue cathartic, sometimes acting as an emetic, in the dose of a tablespoonful, repeated every day, or less frequently if it act with violence.*

SANGUINARIA. *U. S.*

Bloodroot.

The rhizoma of Sanguinaria Canadensis. *U. S.*

Sanguinaria. *Sex. Syst.* Polyandria Monogynia. — *Nat. Ord.* Papaveraceæ. *Gen. Ch. Calyx* two-leaved. *Petals* eight. *Stigma* sessile, two-grooved. *Capsule* superior, oblong, one-celled, two-valved, apex attenuated. *Receptacles* two, filiform, marginal. *Nuttall.*

Sanguinaria Canadensis. Willd. *Sp. Plant.* ii. 1140; Bigelow, *Am. Med. Bot.* i. 75; Barton, *Med. Bot.* i. 31. The *bloodroot*, or, as it is sometimes called, *puccoon*, is an herbaceous perennial plant. The root (rhizoma) is horizontal, abrupt, often contorted, about as thick as the finger, two or three inches long, fleshy, of a reddish-brown colour on the outside, and brighter red within. It is furnished with numerous slender radicles, and makes offsets from the sides, which succeed the old plant. From the end of the root arise the scape and leafstalks, surrounded by the large sheaths of the bud. These spring up together, the folded leaf enveloping the flower-bud, and rolling back as the latter expands. The leaf, which stands upon a long channeled petiole, is reniform, somewhat heart-shaped, deeply lobed, smooth, yellowish-green on the upper surface, paler or glaucous on the under, and strongly marked by orange-coloured veins. The scape is erect, round, and smooth, rising from a few inches to a foot, and terminating in a single flower. The calyx is two-leaved and deciduous. The petals, varying from seven to fourteen, but usually about eight in number, are spreading, ovate, obtuse, concave, mostly white, but sometimes slightly tinged with rose or purple. The stamens are numerous, with yellow filaments shorter than the corolla, and orange oblong anthers. The germ is oblong and compressed, with a sessile, persistent stigma. The capsule is oblong, acute at both ends, two-valved, and contains numerous oval, reddish-brown seeds. The whole plant is pervaded by an orange-coloured sap, which flows from every part when broken, but is of the deepest colour in the root.

The bloodroot is one of the earliest and most beautiful spring flowers of North America. It grows abundantly throughout the whole United States, delighting in loose, rich soils, and shady situations, and flowering in March and April. After the fall of the flower, the leaves continue to grow, and, by the middle of summer, have become so large as to give the plant an entirely different aspect. Except the seeds, all parts of the plant are active; but the root only is officinal.

* Dr. B. H. Stratton, of Mount Holly, N. J., has found a syrup prepared from the berries useful as an alterative, employing it in all cases to which sarsaparilla is thought to be applicable. To prepare the syrup, he mixes the juice of the berries and sugar, in the proportion of a pint of the former to a pound of the latter, boils sufficiently, and adds to each pint of the syrup an ounce of the strongest brandy. The syrup must be kept in well-closed bottles in a cool place. The dose is from a dessertspoonful to a tablespoonful three times a day. (*N. J. Med. Reporter*, vii. 446.)

This, when dried, is in pieces from one to three inches long, from a quarter to half an inch or more in thickness, flattened, much wrinkled and twisted, often furnished with abrupt offsets and many short fibres, of a reddish-brown colour externally, with a spongy uneven fracture, the surface of which is at first bright-orange, but becomes of a dull-brown by long exposure. The colour of the powder is a brownish orange-red. Sanguinaria has a faint narcotic odour, and a bitterish very acrid taste, the pungency of which remains long in the mouth and fauces. It yields its virtues to water and alcohol. The late Dr. Dana, of New York, obtained from it a peculiar alkaline principle, denominated by him *sanguinarina*, upon which the acrimony, and perhaps the medical virtues of the root depend. It may be procured, according to Dana, by infusing the finely powdered root in hot water or diluted muriatic or acetic acid, precipitating with water of ammonia, collecting the precipitated matter, boiling it in water with pure animal charcoal, filtering off the water, treating the residue left upon the filter with alcohol, and finally evaporating the alcoholic solution. (*Ann. Lyc. of Nat. Hist., New York*, ii. 250.) It may also be conveniently procured by a process similar to that employed by Probst for obtaining chelerythrin from celandine. This consists in forming a strong ethereal tincture of the root, passing through this muriatic acid gas, drying the precipitated muriate which is insoluble in ether, dissolving it in hot water, filtering, precipitating by ammonia, drying the precipitate, dissolving it in ether, decolorizing by animal charcoal, precipitating by means of muriatic acid gas, and decomposing the muriate as before. (*Chem. Gaz.*, i. 145.) Dr. James Schiel, of St. Louis, Missouri, who has determined the identity of sanguinarina with chelerythrin, gives the following as the simplest process of preparing either alkaloid. Digest the root with water strongly acidulated with sulphuric acid, precipitate with ammonia, dry the precipitate, dissolve it in ether, treat with animal charcoal, filter, and precipitate with sulphuric acid dissolved in ether. A pure sulphate is thus obtained, which may be decomposed in the ordinary method, to obtain the alkaloid. (*Silliman's Journ.*, Sept. 1855.) Sanguinarina is a white pearly substance, of an acrid taste, very sparingly soluble in water, soluble in ether, and very soluble in alcohol. With the acids it forms salts soluble in water, all of which have some shade of red, crimson, or scarlet, and form beautiful red solutions. They are acrid and pungent to the taste, particularly the muriate and acetate. From these facts it would appear that the red colour and acrid properties of the bloodroot may be owing to the presence of some native salt of sanguinarina, which is decomposed by ammonia in the separation of the organic alkali. The formula of sanguinarina is $C_{37}H_{16}NO_8$. A second alkaloid has been extracted from bloodroot by Riegel, and is considered by him as analogous to the *porphyroxin* found by Merck in opium.* (*Chem. Gaz.*, iv. 198.) Mr. E. S. Wayne, of Cincinnati, has discovered a third alkaloid, which he found in the ether after the precipitation of the sulphate of sanguinarina in the process of Dr. Schiel. It is pale-red, tasteless, insoluble in water, soluble in alcohol and ether, and unites with muriatic and sulphuric acids to form crystallizable compounds, of a deep-red colour. (*Am. Journ. of Pharm.*, xxviii. 522.) Dr. Gibb proposes for this principle the name of *puccin*. According to that writer, bloodroot contains, besides the three alkaloids referred to, chelidonic acid, fecula, sugar, albumen, resin, fixed oil, gum, ex-

* This alkaloid was obtained by treating the root with water acidulated with acetic acid, precipitating the sanguinarina by ammonia, neutralizing the "wash-water" by acetic acid, precipitating by infusion of galls, digesting the precipitate previously washed and dried in an alcoholic solution of potassa, passing carbonic acid through the solution, and distilling off the alcohol. The residue was exhausted with water, the liquid evaporated, and what remained extracted by ether, which yielded it, on evaporation, in the form of a dirty-white crystalline mass. By dissolving this in alcohol, decolorizing with animal charcoal, and crystallizing, it was obtained in colourless tabular crystals, without taste or smell, very sparingly soluble in water, more readily soluble in alcohol, and forming with the acids colourless, bitter, crystallizable salts, soluble in water. (*Chem. Gaz.*, iv. 198.) Dr. Geo. D. Gibb, of London, who has made a partial analysis of the root, denies the identity of this principle with porphyroxin. (*Pharm. Journ.*, March, 1860, p. 46.) It awaits further investigation, and a proper name. (*Note to the twelfth edition.*)

tractive, and lignin. (*Pharm. Journ.*, March, 1860, p. 461.) The virtues of the root are said to be rapidly deteriorated by time. Mr. Thos. M. Newbold has extracted from sanguinaria an organic acid, which, though agreeing with chelidonic acid in some of its characteristics, differs in others, and must, therefore, be considered a distinct principle. According to Mr. Newbold, it is a non-volatile liquid; and he proposes for it the name of *sanguinarinic acid.* (*Am. Journ. of Pharm.*, Nov. 1866, p. 496.)

Medical Properties and Uses. Sanguinaria is an acrid emetic, with stimulant narcotic powers. In small doses it excites the stomach, and accelerates the circulation; more largely given, produces nausea and consequent depression of the pulse; and in the full dose occasions active vomiting. It is also expectorant, and is said to be emmenagogue. The effects of an overdose are violent emesis, a burning sensation in the stomach, tormenting thirst, faintness, vertigo, dimness of vision, and alarming prostration. Four persons lost their lives at Bellevue Hospital, New York, in consequence of drinking largely of tincture of bloodroot, which they mistook for ardent spirit. (*Am. Journ. of Med. Sci.*, N. S., ii. 506.) Snuffed up the nostrils, bloodroot excites much irritation, attended with sneezing. Upon fungous surfaces it acts as an escharotic. It has been given in typhoid pneumonia, catarrh, pertussis, croup, phthisis pulmonalis, hydrothorax, scarlatina, rheumatism, jaundice, dyspepsia, amenorrhœa, dysmenorrhœa, and other affections, either as an emetic, nauseant, alterative, or emmenagogue; and its virtues are highly praised by many judicious practitioners. Dr. Mothershead, of Indianapolis, speaks in the strongest terms of its efficacy as an excitant to the liver, given in alterative doses. (See *Wood's Quart. Retrosp.*, ii. 80.)

The dose with a view to its emetic operation is from ten to twenty grains, given in powder or pill. The latter form is preferable, in consequence of the great irritation of throat produced by the powder when swallowed. For other purposes the dose is from one to five grains, repeated more or less frequently according to the effect desired. The medicine is sometimes given in infusion or decoction, in the proportion of half an ounce to the pint. The emetic dose of this preparation is from half a fluidounce to a fluidounce. The tincture is officinal.* A fluid extract may be prepared in the same manner as the officinal fluid extract of ergot. (See *Extractum Ergotæ Fluidum.*) One fluidrachm represents the virtues of sixty grains of the root; and the emetic dose, therefore, would be from ten to twenty minims. An infusion in vinegar has been employed advantageously, as a local application, in obstinate cutaneous affections; and Dr. R. G. Jennings has found it more efficient as a gargle, in the sorethroat of scarlatina, than any other that he has employed. (*Stethoscope*, ii. 182.) It has been used also in diphtheria. Dr. Stephens, of Ceres, New York, has found the powder useful as an errhine, in coryza, combined with cloves and camphor. (*N. Y. Journ. of Med.*, N. S., iv. 358.) Mixed with chloride of zinc, and made into a paste with flour and water, it has been used by Dr. J. W. Fell as a local remedy in cancer, with asserted success.

In reference to the effects of sanguinarina, the late Dr. Wm. Tully found it, in large doses, to produce vertigo, dilatation of the pupil, a haggard expression of face, nausea, coldness of the extremities, cold sweats, and diminished frequency with irregularity of the pulse. The late Prof. R. P. Thomas, of Philadelphia, who experimented with it on himself and others, in medicinal doses, using both the alkaloid and its salts, gave the following statement of its powers. In doses varying from one-twelfth to one-eighth of a grain, it acted as an expectorant, without disturbing the stomach. One-sixth or one-fourth of a grain, given every

* Mr. T. S. Wiegand proposes the following formula for *a syrup of bloodroot.* Take of the root in coarse powder ℥viij, acetic acid f℥iv, water Ov, sugar lbij. Add to the powder two fluidounces of the acetic acid mixed with a pint of the water, macerate for three days, transfer to a percolator, and displace with the remainder of the water mixed with the remainder of the acetic acid. Evaporate the infusion obtained, by means of a water-bath, to eighteen fluidounces, then add the sugar, and form a syrup, straining if necessary. From one to two fluidrachms should operate as an emetic. (*Am. Journ. of Pharm.*, xxvi. 108.)—*Note to the eleventh edition.*

two or three hours, generally produced nausea, and sometimes vomited. Half a grain in solution, given at intervals of ten minutes, almost invariably vomited after the second or third dose. Under the influence of one-eighth or one-sixth of a grain, given every three hours, for two days or more, the pulse was generally reduced from five to fifteen beats in the minute. He found no alterative effect, and none of any kind directly upon the liver. (*Proceedings of the Am. Med. Assoc.*, A. D. 1863, p. 219.)

Pterocarpus santalinus. Willd. *Sp. Plant.* iii. 906; Woodv. *Med. Bot.* p. 430, t. 156. This is a large tree with alternate branches, and petiolate ternate leaves, each simple leaf being ovate, blunt, somewhat notched at the apex, entire, veined, smooth on the upper surface, and hoary beneath. The flowers are yellow in axillary spikes, and have a papilionaceous corolla, of which the *vexillum* is obcordate, erect, somewhat reflexed at the sides, toothed and waved, the *alæ* spreading with their edges apparently toothed, and the *carina* oblong, short, and somewhat inflated. The tree is a native of India, attaining the highest perfection in mountainous districts, and inhabiting especially the mountains of Coromandel and Ceylon. Its wood is the officinal *red saunders*, though there is reason to believe that the product of other trees is sold by the same name.

The wood comes in roundish or angular billets, internally of a blood-red colour, externally brown from exposure, compact, heavy, and fibrous. It is kept in the shops in the state of small chips, raspings, or coarse powder.

Red saunders has little smell or taste. It imparts a red colour to alcohol, ether, and alkaline solutions, but not to water; and a test is thus afforded by which it may be distinguished from some other colouring woods. The alcoholic tincture produces a deep-violet precipitate with sulphate of iron, a scarlet with bichloride of mercury, and a violet with the soluble salts of lead. The colouring principle, which was separated by Pelletier, and called by him *santalin*, is of a resinous character, scarcely soluble in cold water, more so in boiling water, very soluble in alcohol, ether, acetic acid, and alkaline solutions, but slightly in the fixed and volatile oils, with the exception of those of lavender and rosemary, which readily dissolve it. It is precipitated when acids are added to the infusion of the wood, prepared with an alkaline solution. Weyermann and Hœfferly have found it to possess acid properties. For an analysis of red sandal wood by Mr. H. Dussance, New Lebanon, New York, the reader is referred to the *Am. Journ. of Pharm.* (Jan. 1860, p. 6). The wood has no medical virtues, and is employed solely for the purpose of imparting colour.

SANTONICA. *U. S., Br.*

Santonica. Levant Wormseed.

The unexpanded flowers and peduncles of Artemisia Contra, and of other species of Artemisia. *U. S.* The unexpanded flower-heads of an undetermined species of Artemisia. Imported from Russia. *Br.*

European Wormseed. Santonici Semen. Semen Cynæ. Semen Contra. This product, though discarded from the Dublin Pharmacopœia of 1850, has been recognised in the British Pharmacopœia, as well as in the late edition of our own. It was formerly ascribed by the Dublin College, in accordance with the general belief at one time, to *Artemisia Santonica* or *Tartarian southernwood;* but upon insufficient grounds. European wormseed is of two kinds; one called the Aleppo, Alexandria, or Levant wormseed, the other Barbary wormseed. The former is supposed to be the product of *Artemisia Contra,* which grows in Persia, Asia Minor, and other parts of the East. It consists in fact not of the seeds, but of the small globular unexpanded flowers of the plant, mixed with their broken peduncles, and with minute, obtuse, smooth leaves. It has a greenish colour, a very strong aromatic odour increased by friction, and a very bitter disagreeable taste. The Barbary wormseed is thought by some to be derived from *Artemisia Judaica,* by others from the *A. glomerata* of Sieber, both of which grow in Palestine and Arabia. It consists of broken peduncles, having the calyx sometimes attached to their extremity. The calyx is also sometimes separate, consisting of very small linear obtuse leaflets. The flowers are wanting, or in the shape of minute globular buds. All these parts are covered with a whitish down, which serves to distinguish this variety from the wormseed of the Levant. It is, moreover, lighter and more coloured than the latter. Its smell and taste are the same. It is the former variety which is recognised by the two Pharmacopœias. The British gives the following description of the medicine. "Flower-heads rather more than a line in length and nearly half a line in breadth, fusiform, blunt at each end, pale greenish-brown, smooth; resembling seeds in appearance, but consisting of imbricated involucral scales with a green midrib, enclosing four or five tubular flowers."

Wormseed contains a volatile oil and a resinous extractive matter, to which its virtues have been ascribed. But it probably owes its efficiency, in a greater degree, to a peculiar principle called *santonin.* This is crystallizable, colourless, tasteless but leaving a slight sense of acrimony in the mouth, inodorous, soluble in ether and alcohol, and nearly insoluble in water. Its alcoholic solution has a decided bitterness. Though neuter in its action upon test-paper, it combines with the alkalies to form soluble and crystallizable salts. Having been adopted by the U. S. and Br. Pharmacopœias, with processes for its preparation, it will be treated of more fully in the second part of the work. (See *Santoninum.*)

The two kinds of wormseed above described have long been celebrated as a vermifuge; and the title of *semen contra,* by which they are designated in many works on pharmacy, originated in their anthelmintic property. Their influence on the system is not very striking. A curious effect, however, is recorded as having resulted from a large dose of wormseed, which was ascribed to the santonin. Several individuals of a family who had taken the remedy as a vermifuge, along with the expected results, were affected with a change in the perception of colours, red being converted into orange, and blue into green. (*Ann. de Thérap.,* A. D. 1852, p. 234.) Santonica may be given in powder or infusion. The dose in substance is from ten to thirty grains, which should be repeated morning and evening for several days, and then followed by a brisk cathartic. It is little used in this country, having given place to the seeds of *Chenopodium anthelminticum,* which are universally known among us by the name of wormseed. In Europe it has been superseded, to a considerable extent, by santonin, which is much employed.

Soft Soap.

Soap made with olive oil and potash. *Br.*

Savon mou, Savon vert, Savon à base de potasse, *Fr.;* Schmierseife, Kaliseife, *Germ.*

Soaps embrace all those compounds which result from the reaction of salifiable bases with fats and oils. Fats and oils, as has been explained under the titles *Adeps* and *Olea*, consist generally of three principles, two solid, differing in fusibility, called *stearin* and *margarin*, and one liquid, called *olein*, of which there are two varieties. Stearin is found most abundantly in fats which are firm and solid, as suet and tallow; margarin in human fat; and olein in the oils. When the fats and oils undergo *saponification* by reaction with a salifiable base, these three principles are decomposed into oily acids peculiar to each, discovered by Chevreul, and called stearic, margaric, and oleic acids, which unite with the base to form the soap, and into a sweet principle not saponifiable, called glycerin, which is set free. Hence it follows that stearin is a stearate, margarin a margarate, and olein an oleate of glycerin, and that the fats and oils are mixtures of these three oily salts. Hence, also, it is obvious that soaps are mixed stearates, margarates, and oleates of various bases. *Stearic acid* is a firm white solid, like wax, fusible at 167°, greasy to the touch, pulverizable, soluble in alcohol, very soluble in ether, but insoluble in water. In the impure state it is used as a substitute for wax in making candles. *Margaric acid* has the appearance of fat, and is fusible at 140°. *Oleic acid* is an oily liquid, insoluble in water, soluble in alcohol and ether, lighter than water, crystallizable in needles a little below 32°, and having a slight smell and pungent taste. *Glycerin* will be described under a separate head. (See *Glycerina.*)

Soaps are divided into the soluble and insoluble. The soluble soaps are combinations of the oily acids with soda, potassa, and ammonia; the insoluble consist of the same acids united with earths and metallic oxides. It is the soluble soaps only that are detergent, and to which the name *soap* is usually applied. Several of the insoluble soaps are employed in pharmacy; as, for example, the soap of the protoxide of lead, or lead plaster, and the soap of lime, or lime liniment. (See *Emplastrum Plumbi* and *Linimentum Calcis.*) The two officinal soaps, here described, are of the soluble kind. One is a soda soap, made with olive oil (Castile soap), the other a potassa soap (soft soap).* The soap of ammonia is noticed elsewhere. (See *Linimentum Ammoniæ.*)

The consistency of the fixed alkaline soaps depends partly on the nature of the oil or fat, and partly on the alkali present. Soaps are harder the more stearate and margarate they contain, and softer when the oleate predominates; and, as it respects the alkali present, they are harder when formed with soda, and softer when containing potassa. Hence it is that of pure soaps, considered as salts, stearate of soda is the hardest and least soluble, and oleate of potassa the softest and most soluble.

Preparation. The following is an outline of the process for making soap. The oil or fat is boiled with a solution of caustic alkali, until the whole forms a thick mass, which can be drawn out into long clear threads. After the soap is completely formed, the next step is to separate it from the excess of alkali, the glycerin, and redundant water. This is effected by adding common salt, or a very strong alkaline lye, in either of which the soap is insoluble. The same end may be attained by boiling down the solution until the excess of alkali forms a strong alkaline solution, which acts the same part in separating the soap as the addition of a similar solution. As soon as the soap is completely separated, it rises to the surface; and, when it has ceased to froth in boiling, it is ladled out into wooden frames to congeal, after which it is cut into bars by means of a wire. The soap, as first separated, is called *grain soap.* It may be purified by dissolving it in an alkaline lye, and separating it by common salt. During this process the impurities subside, and the soap combines with more

water; and hence it becomes weaker, although purer and whiter. If the grain soap is not purified it forms *marbled soap;* the coloured streaks arising principally from an insoluble soap of oxidized iron. Sometimes the marbled appearance is produced by adding to the soap, as soon as it is completely separated, a fresh portion of lye, and immediately afterwards a solution of sulphate of iron. The black oxide of iron is precipitated, and gives rise to dark-coloured streaks, which, by exposure to the air, become red in consequence of the conversion of the black into the sesquioxide of iron. For an account of the process of Mr. R. A. Tilghman, of this city, patented in 1854, for manufacturing soap by subjecting a mixture of fatty matters and a solution of carbonated alkali to a high temperature under pressure, see the *Am. Journ. of Pharm.* (xxvii. 121).

The officinal *soap* (Sapo, *U. S.;* Sapo Durus, *Br.*) is an olive oil soda soap, made on the same general plan as that just explained.

Common Soap (Sapo Vulgaris, *U. S.* 1850) is also a soda soap; but, instead of olive oil, it contains concrete animal oil. This soap corresponds with the white soap of northern European countries and of the United States, and is formed usually from barilla and tallow. In Scotland it is manufactured from kelp and tallow. It was introduced into the list of the U. S. Pharmacopœia as the only proper soap for making opodeldoc; but, as this preparation has been discarded in the existing edition, this variety of soap has been dismissed along with it.

Soft Soap (Sapo Mollis, *Br.*) is prepared on the same general principles as hard soap; potash being employed as the alkali, and a fatty matter rich in olein, as the oil. The French soft soap is made with the seed oils, such as rapeseed, hemp-seed, &c.; the Scotch and Irish, with fish oil and some tallow; and our own with refuse fat and grease. A lye of wood-ashes is the form of potash usually employed. In forming the soap it is necessary that it should continue dissolved in the alkaline solution, instead of being separated from it. Hence soft soap is a soap of potassa, completely dissolved in the solution of its alkali, which is consequently present in excess. A soap of potassa is sometimes made with a view to its conversion into a soda soap. This is effected by the addition of an equivalent quantity of common salt, which, by double decomposition, generates a soap of soda, and chloride of potassium in solution. After this change is effected, a further addition of salt separates the soda soap formed. Soft soap is said to be largely adulterated in France with starch, which very much improves its appearance. The fraud may be instantly detected by means of the microscope, which will reveal the starch granules. (*Journ. de Pharm.*, 4e sér., v. 179.)

Besides the officinal soaps of the U. S. and Br. Pharmacopœias, there are many other varieties, more or less used for medicinal or economical purposes. The officinal soap of the French Codex (1837), called *amygdaline soap* (*almond oil soap*), is formed of caustic soda and almond oil, and is directed to be kept for two months exposed to the air, before being used. *Starkey's soap*, also officinal in the Codex, is prepared by uniting, by trituration, equal parts of carbonate of potassa, oil of turpentine, and Venice turpentine. *Beef's marrow soap* is a fine animal oil soap, also included in the French standard of pharmacy. *Windsor soap* is a scented soda soap, made of one part of olive oil and nine parts of tallow. *Eau de luce* (*aqua luciæ*) is a kind of liquid soap, formed by mixing a tincture of oil of amber and balsam of Gilead with water of ammonia. *Transparent soap* is prepared by saponifying kidney fat with soda free from foreign salts, drying the resulting soap, dissolving it in alcohol, filtering and evaporating the solution, and running it into moulds when sufficiently concentrated. The soap is yellow or yellowish-brown, and preserves its transparency after desiccation. *Palm soap* is prepared from soda and palm oil, to which tallow is added to increase its firmness. If it be wanted white, the palm oil may be bleached by heat, bichromate of potassa with sulphuric acid, chlorine, or exposure to the sun. This soap has a yellowish colour, and the agreeable odour of violets derived from the oil. *Soap balls* are prepared by dissolving soap in a little water, and then forming it with starch into a mass of the proper consist-

ence. *Common yellow soap* (*rosin soap*) derives its peculiarities from an admixture of rosin and a little palm oil with the tallow employed; the oil being added to improve its colour. Silicate of soda has, to some extent, been substituted for rosin, as more economical. (*Am. Journ. of Pharm.*, Sept. 1863, p. 466.) Large quantities of lard oil (nearly pure olein) are manufactured into soap.*

All the varieties of soap, except a few of the fancy sort and the olive oil soaps, are manufactured in the United States. The latter, which are chiefly used for medicinal purposes, are imported from France.

Properties. Soap, whatever may be its variety, has the same general properties. Its aspect and consistence are familiar to every one. Its smell is peculiar, and taste slightly alkaline. It is somewhat heavier than water, and therefore sinks in that liquid. Exposed to heat it quickly fuses, swells up, and is decomposed. It is soluble in water, and more readily in hot than in cold. Potassa soaps and those containing oleic acid are far more soluble than the soda soaps, especially those in which the stearates and margarates predominate. Acids, added to an aqueous solution of soap, combine with the alkali, and set free the oily acids, which, being diffused through the water, give it a milky appearance. Its decomposition is also produced by metallic salts, which invariably give rise to insoluble soaps. Soap is soluble in cold, and abundantly in boiling alcohol. This solution constitutes the *tincture of soap*, and forms a very convenient test for discovering lime in natural waters. As the tincture sometimes gelatinizes, it is proposed by M. Bjorklund to remedy this inconvenience by employing soap in the nascent state, that is, containing a large proportion of water. (*Journ. de Pharm.*, 4e sér., ii. 179, A. D. 1865.) The efficacy of soap as a detergent depends upon its power of rendering grease and other soiling substances soluble in water, and therefore capable of being removed by washing. The chief adulterations in soap are lime, gypsum, heavy spar, steatite, and pipeclay. When adulterated with these substances, it will not be entirely soluble in alcohol. According to Dr. Riegel, glue is an occasional adulteration in Spanish soap, discoverable also by its insolubility in alcohol. The same impurity is sometimes found in other soaps.†

Olive oil soda soap (Sapo), otherwise called *Castile* or *Spanish soap*, is a hard soap, and is presented under two principal varieties, the white and the marbled. *White Castile soap*, when good, is of a pale grayish-white colour, incapable of giving an oily stain to paper, devoid of rancid odour or strong alkaline qualities, and entirely soluble both in water and alcohol. It should not feel greasy, nor grow moist, but, on the contrary, should become dry by exposure to the air, without exhibiting any saline efflorescence. This variety of soap contains about 21 per cent. of water. Sometimes it contains a larger proportion of water, with which the soap is made to combine by the manufacturer, with the fraudulent intention of increasing its weight. Soap, thus adulterated, is known by its unusual whiteness, and by its suffering a great loss of weight in a dry air. The proportion of water may be ascertained by introducing the soap into a saturated solution of chloride of sodium, and boiling; when the soap, nearly free from water, concretes into a solid mass. *Marbled Castile soap* is harder, more alkaline, and more constant in its composition than the other variety. It contains about 14 per cent. of water. Having less water than the white Castile, it is a stronger and more economical soap; but at the same time less pure. The impurity arises from the veins of marbling, consisting of ferruginous matter, as already explained. Soap made with animal fat, with the probable addition of

* Upon the supposition that the detergent property of soap depends exclusively on the alkali it contains, and is consequently proportionate to the quantity of that ingredient, a mode of estimating the relative value of soaps has been suggested by R. Graeger, based on the equivalent of the fatty constituent; those soaps being the strongest, of which the acid has the lowest combining number. (See *Am. Journ. of Pharm.*, July, 1861, p. 355.)

† For a mode of estimating the impurities in soap by the volumetric method, by which the character of any sample of soap may be hastily ascertained, with sufficient accuracy for ordinary purposes, see a paper, by M. Pons, in the *Journ. de Pharm. et de Chim.* (4e sér., i. 290).—*Note to the thirteenth edition.*

silicate of soda, has been sold for Castile soap. (*Am. Journ. of Pharm.*, March, 1864, p. 102.)

Animal oil soda soap (Sapo Vulgaris) is a hard soap, of a white colour, inclining to yellow. It is made from tallow and caustic soda. This soap possesses the same general properties as the olive oil soda soap.

Soft soap (Sapo Mollis), as made in this country, is semi-fluid, slippery, capable of being poured from one vessel to another, and of a dirty-brownish-yellow colour. This soap always contains an excess of alkali, which causes it to act more powerfully as a detergent than hard soap. It also contains the glycerin of the fatty matters, which is always separated from hard soap. In the Br. Pharmacopœia it is directed to be made from olive oil and potash; but Dr. Pereira states that he has not been able to meet with it in England. That made in France has a greenish colour and the consistence of soft ointment, and is composed of hempseed oil and potash. It is called, in the French Codex, *savon vert*. Sometimes it is manufactured from the dregs of olive oil.

Incompatibles. Soap is decomposed by all the acids, earths, and earthy and metallic salts. Acids combine with the alkali, and set free the oily acids of the soap; the earths unite with the oily acids and separate the alkali; while the earthy and metallic salts give rise, by double decomposition, to an insoluble soap of their base, and a saline combination between their acid and the alkali of the soap. Hard waters, in consequence of their containing salts of lime, decompose and curdle soap. They may be rendered soft, and fit for washing, by adding sufficient carbonate of soda or of potassa to precipitate all the lime.

Composition. It has been already explained that soap consists of certain oily acids, united with an alkali. As olive oil is a compound of margarin and olein, so the officinal "soap" is a mixed margarate and oleate of soda. The former officinal "common soap" is principally a stearate of soda; and "soft soap," as defined in the Br. Pharmacopœia, is a mixed margarate and oleate of potassa. The most important soaps have the following composition in the hundred parts. *Marseilles white soap*,—soda 10·24, margaric acid 9·20, oleic acid 59 20, water 21·36. (*Braconnot.*) *Castile soap*, very dry,—soda 9·0, oily acids 76·5, water 14·5. (*Ure.*) *Glasgow soft soap*,—potassa 9·0, oily acids 43·7, water 47·3. (*Ure.*) *French soft soap*,—potassa 9·5, oily acids 44, water 46·5. (*Thenard.*) Most soaps, it is perceived, contain a large proportion of water.

Medical Properties. Soap possesses the properties of a laxative, antacid, and antilithic. It is seldom given alone, but frequently in combination with rhubarb, the astringency of which it has a tendency to correct. Thus combined, it is often administered in dyspepsia, attended with constipation and torpor of the liver. As it is readily decomposed by the weakest acids, which combine with the alkali, it often proves useful in acidity of the stomach, and has been recommended as a remedy in the uric acid diathesis; but it possesses no power to dissolve calculi, as was once supposed. Externally, soap is a stimulating discutient, and as such has been used by friction in sprains and bruises. The late Dr. A. T. Thomson found much benefit to result from rubbing the tumid abdomen of children in mesenteric fever, morning and evening, with a strong lather of soap. For the cure of itch, Dr. Schubert recommends a mixture of soft soap and salt, in the proportion of eight ounces of the former to four of the latter, dissolved in a quart of water. With this solution, previously warmed, the patient is to be rubbed, night and morning, until a cure is effected, which generally takes place in three days. M. Thenard recommends a solution of soap as an infallible remedy against the bug (*punaise*, Fr.), which, as well as the egg, is destroyed by a hot solution, made by boiling together one part of soap with fifty parts of water. (*Journ. de Pharm.*, 3e sér., xxviii. 280.) In constipation of the bowels, particularly when arising from hardened feces in the rectum, a strong solution of soap, especially of soft soap, forms a useful enema. When the latter is used, two tablespoonfuls may be dissolved in a pint of warm water. In pharmacy, soap is frequently employed for the purpose of giving a proper consistence to pills; but care must be taken not to associate it with a substance which may be decomposed by it. It

is also an ingredient in some liniments and plasters. In toxicology it is used as a counter-poison for the mineral acids, and should always be resorted to, in poisoning by these agents, without a moment's delay, and its use continued until magnesia, chalk, or the bicarbonate of soda or of potassa can be obtained. The mode of administration, in these cases, is to give a teacupful of a solution of soap, made by dissolving it in four times its weight of water, every three or four minutes, until the patient has taken as much as he can swallow. The dose of soap is from five grains to half a drachm, given in the form of pill.

SARSAPARILLA. *U. S.*

Sarsaparilla.

The root of Smilax officinalis (*Humboldt and Bonpland*), and of other species of Smilax. *U. S.*

Off. Syn. SARSÆ RADIX. *Jamaica Sarsaparilla.* The dried root of Smilax officinalis. *Br.*

Salsepareille, *Fr.;* Sarsaparille, *Germ.;* Salsapariglia, *Ital.;* Zarzaparilla, *Span.*

SMILAX. *Sex. Syst.* Diœcia Hexandria. — *Nat. Ord.* Smilaceæ.

Gen. Ch. MALE. *Calyx* six-leaved. *Corolla* none. FEMALE. *Calyx* six-leaved. *Corolla* none. *Styles* three. *Berry* three-celled. *Seeds* two. *Willd.*

Formerly, *Smilax Sarsaparilla* was admitted by most of the standard authorities as the source of this drug; but it is probable that none of the sarsaparilla of the shops was ever obtained from it. *S. Sarsaparilla* is a native of the United States; and the medicine has never, within our knowledge, been collected in this country. It is not among the eleven species of *Smilax* described by Humboldt, Bonpland, and Kunth, who indicate *S. officinalis*, *S. syphilitica*, and *S. Cumanensis*, especially the first, as the probable sources of the drug exported from Mexico and the Spanish Main. In the present state of our knowledge, it is impossible to decide with certainty from what species the several commercial varieties of the drug are respectively derived. This much is certain, that they do not proceed from the same plant. Of the many species belonging to this genus, few possess any medicinal power; and Hancock states that of the six or eight which he found growing in the woods of Guiana, only one presented in any degree the sensible properties of the genuine sarsaparilla, the rest being insipid and inert. The root (rhizoma) of *Smilax China*, a native of China and Japan, has been employed under the name of *China Root* for similar purposes with the officinal sarsaparilla. As it occurs in commerce, it is in pieces from three to eight inches long and an inch or two thick, usually somewhat flattened, more or less knotty, often branched, of a brownish or grayish-brown colour externally, whitish or of a light flesh-colour internally, without odour, and of a taste flat at first, but afterwards very slightly bitterish and somewhat acrid, like that of sarsaparilla. The root of *Smilax aspera* is said to be employed in the south of Europe as a substitute for sarsaparilla; but it has little reputation. The East India Sarsaparilla, which was at one time referred to this species of Smilax, is the product of *Hemidesmus Indicus*. (See *Hemidesmus*.) We shall briefly describe S. Sarsaparilla, on account of its former officinal rank, and afterwards such other species as are believed to yield any portion of the drug. All of them are climbing or trailing plants, with prickly stems; a character expressed in the name of the medicine, which is derived from two Spanish words (*zarza* and *parilla*), signifying a small thorny vine.

Smilax Sarsaparilla. Willd. *Sp. Plant.* iv. 776; Woodv. *Med. Bot.* p. 161.

t. 62. The stem of this plant is long, slender, shrubby, angular, and beset with prickles. The leaves are unarmed, ovate-lanceolate with about five nerves, somewhat glaucous beneath, and supported alternately upon footstalks, at the bases of which are long tendrils. The flowers usually stand, three or four together, upon a common peduncle, which is longer than the leafstalk. This species is indigenous, growing in swamps and hedges in the Middle and Southern States.

S. officinalis. Humb. and Bonpl. *Plant. Æquinoct.* i. 271. In this species the stem is twining, angular, smooth, and prickly; the young shoots are unarmed; the leaves ovate-oblong, acute, cordiform, five or seven-nerved, coriaceous, smooth, twelve inches long and four or five broad, with footstalks an inch long, smooth, and furnished with tendrils. The young leaves are lanceolate-oblong, acuminate, and three-nerved. According to Humboldt, the plant abounds on the river Magdalena, in New Granada. Large quantities of the root are sent down the river to Mompox and Carthagena.

S. syphilitica. Willd. *Sp. Plant.* iv. 780. The stem is round and smooth; armed at the joints with from two to four thick, straight prickles; and furnished with oblong-lanceolate, acuminate, three-nerved, coriaceous, shining leaves, which are a foot in length, and terminate by a long point. The plant was seen by Humboldt and Bonpland in New Granada, upon the banks of the river Cassiquiare, and by Martius in Brazil, at Yupura and near the Rio Negro. It has been supposed to yield the Brazilian sarsaparilla.

S. papyracea. Poiret, *Encyc. Méth.* iv. 467. This is an under-shrub with a compressed stem, angular below, and furnished with spines at the angles. Its leaves are elliptical, acuminate, and three-nerved. It inhabits Cayenne and Brazil, chiefly upon the banks of the Amazon and its tributaries, and is thought to yield the variety of sarsaparilla denominated Brazilian. (*Am. Journ. of Pharm.*, xv. 277.) A particular description of a specimen of Smilax, supposed to belong to this species, is given by Professor Bentley in the *London Pharm. Journ.* (x. 470.) It was obtained from Guatemala, and was the source of a variety of commercial sarsaparilla, recently introduced into the market, which Professor Bentley proposes to name Guatemala sarsaparilla.

S. medica. Schlechtendahl, *Linnæa*, vi. 47; Carson, *Illust. of Med. Bot.* ii. 51, pl. 95. This species has an angular stem, armed with straight prickles at the joints, and a few hooked ones in the intervals. The leaves are smooth, bright-green on both sides, shortly acuminate, five-nerved, with the veins prominent beneath. They vary much in form, the lower being cordate, auriculate-hastate; the upper cordate-ovate. In the old leaves, the petiole and midrib are armed with straight subulate prickles. The inflorescence is an umbel of from eight to twelve flowers, with a smooth axillary peduncle, and pedicels about three lines long. Schiede found this plant on the eastern declivity of the Mexican Andes, where the root is collected to be taken to Vera Cruz.

The medicinal species of Smilax grow in Mexico, Guatemala, and the warm latitudes of South America. The roots are very long and slender, and originate in great numbers from a common head or rhizoma, from which the stems of the plant rise. The whole root with the rhizoma is usually dug up, and as brought into market exhibits not unfrequently portions of the stems attached, sometimes several inches in length. The sarsaparilla of commerce comes from different sources, and is divided into varieties according to the place of collection or shipment.

Honduras Sarsaparilla is the variety most used in this country. It is brought from the bay of Honduras, and comes in bundles two or three feet long, composed of several roots folded lengthwise, and secured in a compact form by a few circular turns. These are packed in bales imperfectly covered with skins, each bale containing one hundred pounds or more. The roots are usually connected at one extremity in large numbers in a common head, to which portions of the stems are also attached. In some bundles are many small fibres either lying loose, or still adhering to the roots. The colour of the roots externally is a dirty-grayish or reddish-brown; and the cortical portion beneath the epidermis often appears amylaceous when broken.

The *Jamaica* or *red sarsaparilla* of foreign writers is little known by that name in the United States. The island of Jamaica is merely its channel of exportation to Europe; and it is probably derived originally from Central America. It does not materially differ in properties from Honduras sarsaparilla; its chief peculiarity being the reddish colour of the epidermis, which is also sometimes found in that variety. It is said also to yield a larger proportion of extract, and to contain less starch. As found in commerce, it is in bundles from twelve to eighteen inches long, by four or five in thickness, consisting of long slender roots folded up, with numerous radical fibres attached.

Considerable quantities of the drug are imported from the Mexican ports of Vera Cruz and Tampico. The *Vera Cruz sarsaparilla* comes in large, rather loose bales, weighing about two hundred pounds, bound with cords or leather thongs, and usually containing the roots folded upon themselves, and separately packed. These, as in the Honduras sarsaparilla, consist of a head or caudex with numerous long radicles, which, however, are somewhat smaller than in that variety, and have a thinner bark. They are often also much soiled with earth. This variety was formerly little esteemed; but, from the acrid taste which it possesses, it is probably not inferior in real virtues to the other kinds. It is probably derived from Smilax medica.

Another variety is the *Caracas sarsaparilla*, brought in large quantities from La Guayra. It is in oblong packages, of about one hundred pounds, surrounded with broad strips of hide, which are connected laterally with thongs of the same material, leaving much of the root exposed. The roots, as in the last variety, are separately packed, but more closely and carefully. The radicles are often very amylaceous internally, in this respect resembling the following.

The *Brazilian*, or, as it is sometimes called in Europe, the *Lisbon sarsaparilla*, has been less used in the United States than in Europe, where it has commanded a higher price. Within a few years, however, it has been imported in considerable quantities. It comes from the ports of Para and Maranham, in cylindrical bundles of from three to five feet in length, by about a foot in thickness, bound about by close circular turns of a very flexible stem, and consisting of unfolded roots, destitute of caudex (rhizoma) and stems, and having few radical fibres. It is the variety of which Hancock speaks as celebrated throughout South America by the name of *sarsa of the Rio Negro*, and is considered as the most valuable variety of the drug. It is distinguished by the amylaceous character of its interior structure, and has considerable acrimony. It was said by Martius to be derived from Smilax syphilitica; but Dr. Hancock considers that portion of it which comes from the Rio Negro, and is shipped at Para, as the product of an undescribed species, certainly not S. syphilitica. According to Richard, it has been ascertained to be the product of the S. papyracea of Poiret. (See *Am. Journ. of Pharm.*, xv. 277.)

The variety described by Professor Bentley under the name of *Guatemala sarsaparilla* was collected in the province of Sacatapeques, about ninety miles from the sea. It is in cylindrical bundles about two feet eight inches long by four inches in diameter, composed of separate roots, arranged in parallel order, without rootstalk, and bound together by a few turns of the flexible stem of a monocotyledonous plant. The bundles resemble the Brazilian in arrangement, but are much less compact. It is amylaceous, has considerable acrimony, and is probably one of the most efficient varieties. Professor Bentley ascribes it to S. papyracea. For a particular description of the root, the reader is referred to the *Pharmaceutical Journal* (xii. 472).

Much sarsaparilla has been imported into England from Lima, Valparaiso, and other places on the Pacific coast of South America. It is described by Pereira as bearing a close resemblance to Jamaica sarsaparilla, but yielding a smaller proportion of extract. It is in bundles of about three feet long and nine inches thick, consisting of the roots folded with their heads or rhizomes attached. The epidermis is brown or grayish-brown. Sometimes roots of a light-clay colour are found in the bundles.

In a memoir read by Dr. Berthold Seeman before the London Linnæan Society, the author stated that, after careful examination, he was convinced that the commercial varieties of sarsaparilla, called Brazilian, Jamaica, and Guatemala sarsaparilla, are all the product of one species of Smilax, the *S. officinalis* of Humboldt and Bonpland, and moreover, that the *S. medica* of Schlechtendahl, and the *S. papyracea* of Poiret, are identical with that species. (*Pharm. Journ.*, Feb. 1854, p. 385.)

Properties. The dried sarsaparilla roots are several feet in length, about the thickness of a goose-quill, cylindrical, more or less wrinkled longitudinally, flexible, and composed of a thick exterior cortical portion, covered with a thin easily separable epidermis, of an inner layer of ligneous fibre, and of a central pith. The epidermis is of various colours, generally ash-coloured, grayish-brown, or reddish-brown, and sometimes very dark. The cortical portion is in some specimens whitish, in others brown, and not unfrequently of a pink or rosy hue. It is occasionally white, brittle, and almost powdery like starch. The woody part is usually very thin, and composed of longitudinal fibres, which allow the root to be split with facility through its whole length. The central medulla often abounds in starch.

Sarsaparilla in its ordinary state is nearly or quite inodorous, but in decoction acquires a decided and peculiar smell. To the taste it is mucilaginous and very slightly bitter, and, when chewed for some time, produces a disagreeable acrid impression, which remains long in the mouth and fauces. The root is efficient in proportion as it possesses this acrimony, which is said by some authors to be confined to the cortical portion; while the ligneous fibre and medullary matter are insipid and inert. Hancock avers that all parts are equally acrid and efficacious. The truth is probably between the two extremes; and, as in most medicinal roots, it must be admitted that the bark is more powerful than the interior portions, while these are not wholly inactive. The virtues of the root are communicated to water cold or hot, but are impaired by long boiling. They are extracted also by diluted alcohol. According to Hancock, the whole of the active matter is not extracted by water. He observes in his paper upon sarsaparilla, published in the *London Medico-Botanical Transactions*, when speaking of the sarsaparilla from Para and the Rio Negro, "after exhausting half a pound of this sort by two digestions, boiling, and pressure, I added to the dregs half a pint of proof spirit, and digested this with a gentle heat for a few hours in a close vessel, then affusing hot water to the amount of that taken off from the first boiling, and pressing again, I procured by the last operation about four pints of an infusion which possessed the acrid properties of the sarsa in a much higher degree even than that obtained by the first decoction with simple water." It appears that in South America it is the custom to prepare sarsaparilla by digestion in wine or spirit, or by infusion in water with additions which may produce the vinous fermentation, and thus add alcohol to the menstruum. The same result, as to the superior efficacy of alcohol as a solvent of the acrid principle of sarsaparilla, has been obtained by the French experimentalists.

According to M. Thubeuf, sarsaparilla contains, 1. a peculiar crystalline substance, which is probably the active principle of the root, 2. a colouring substance, 3. resin, 4. starch, 5. lignin, 6. a thick, aromatic fixed oil, 7. a waxy substance, and 8. chloride of potassium and nitrate of potassa. It is said also to contain a minute proportion of volatile oil, and Batka found gum, bassorin, albumen, gluten and gliadine, lactic and acetic acids, and various salts. The proportion of starch is large. Chatin found iodine in Honduras sarsaparilla; but Dr. Winckler, not having succeeded in detecting this principle in any one root, thinks it probable that the specimen examined by Chatin had been exposed to sea-water. (*Pharm. Cent. Blatt*, May 7, 1852.)

Sarsaparillin. (*Smilacin. Pariglin. Salseparine. Parillinic acid.*) The crystalline principle in which the virtues of sarsaparilla reside should be called *sarsaparillin.* It was first discovered by Dr. Palotta, who described it in 1824 under the name of *pariglin.* Subsequently, M. Folchi supposed that he had

found another principle which he called *smilacin*. In 1831, M. Thubeuf announced the discovery of a new substance in sarsaparilla which he named *salseparine*, from the French name of the root. Finally, Batka, a German chemist, towards the end of 1833, published an account of a principle which he had discovered in the root, and which, under the impression that it possessed acid properties, he called *parillinic acid*. M. Poggiale, however, has shown that these substances are identical, though procured by different processes. The following is the process of M. Thubeuf. The root is treated with hot alcohol till deprived of taste. The tincture is submitted to distillation, and seven-eighths of the alcohol drawn off. The remainder is treated with animal charcoal, and filtered at the end of twenty-four or forty-eight hours. The sarsaparillin is deposited in the form of a granular powder. This is dissolved in a fresh portion of alcohol, and crystallized. The alcoholic mother-liquors may be deprived of that portion of the principle which they retain by evaporating to dryness, dissolving the product in water, filtering, again evaporating to dryness, redissolving in alcohol, and crystallizing. *Sarsaparillin* is white, inodorous, almost tasteless in the solid state, but bitter, acrid, and nauseous when dissolved in alcohol or water. It is very slightly soluble in cold water, but more readily in boiling water, which deposits it on cooling. It is very soluble in alcohol, especially at the boiling temperature. Ether and the volatile oils also dissolve it. Its aqueous solution has the property of frothing very much by agitation. M. Beral states that he has procured it pure by distilling, by means of a salt-water bath, a tincture of sarsaparilla prepared with very dilute alcohol. In that case it must be volatile, and we can understand why sarsaparilla suffers in decoction. (See *Am. Journ. of Pharm.*, xii. 245.) The solutions of sarsaparillin are without acid or alkaline reaction. Batka erred in considering it an acid. M. Poggiale found it both in the cortical and medullary part of the root, but most largely in the former. Palotta gave it internally in doses varying from two to thirteen grains, and found it to produce nausea, and to diminish the force of the circulation. It is probably the principle upon which sarsaparilla depends chiefly, if not exclusively, for its remedial powers.

The sarsaparilla of the shops is apt to be nearly if not quite inert, either from age, or from having been obtained from inferior species of Smilax. This inequality of the medicine, with the improper modes of preparing it long in vogue, has probably contributed to its variable reputation. The only criterion of good sarsaparilla to be relied on is the taste. If it leave a decidedly acrid impression in the mouth after having been chewed for a short time, it may be considered efficient; if otherwise, it is probably inert.

Medical Properties and Uses. Few medicines have undergone greater changes of reputation. About the middle of the sixteenth century it was introduced into Europe as a remedy for the venereal complaint, in which it had been found very useful in the recent Spanish settlements in the West Indies. After a time it fell into disrepute, and was little employed till about a century ago, when it was again brought into notice by Sir William Fordyce and others, as a useful adjuvant and corrigent of mercury in lues venerea. Since that period very different opinions have been entertained of it. Some, among whom was Dr. Cullen, considered it wholly inert; others, on the contrary, have had the most unbounded confidence in its powers. The probable cause of much of this discrepancy has been already mentioned. Experience, both among regular practitioners and empirics, would seem to have placed its efficacy beyond reasonable doubt. Its most extensive and useful application is to the treatment of secondary syphilis and syphiloid diseases, and that shattered state of the system which sometimes follows the imprudent use of mercury in these affections. It is also employed, though with less obvious benefit, in chronic rheumatism, scrofulous affections, certain cutaneous diseases, and other depraved conditions of health. Its mode of action is less evident than its ultimate effects. It is said to increase the perspiration and urine; but, allowing it to do so, the effect is too slight to explain its remedial influence; and even that which is produced has been ascribed by

some to the medicines with which it is generally associated, or the liquid in which it is exhibited. In this ignorance of its precise *modus operandi* we call it an alterative, as those medicines are named which change existing morbid actions, without obvious influence over any of the functions.

Sarsaparilla may be given in powder, in the dose of half a drachm three or four times a day. It is, however, more conveniently administered in the form of infusion, decoction, syrup, or fluid extract. (See *these preparations* in *Part* II.) A beer, made by fermenting an infusion of the drug with molasses, is said to be a popular remedy in South America.* The smoke of sarsaparilla has been highly recommended in asthma. (*Journ. de Pharm.*, xviii. 221.)

SASSAFRAS MEDULLA. *U.S.*

Sassafras Pith.

The pith of the stems of Sassafras officinale. *U. S.*

SASSAFRAS RADICIS CORTEX. *U S.*

Bark of Sassafras Root.

The bark of the root of Sassafras officinale. *U. S.*

Off. Syn. SASSAFRAS RADIX. The dried root of Sassafras officinale. *Br.* Sassafras, *Fr.*, *Germ.;* Sassafras, Sassafrasso, *Ital.;* Sasafras, *Span.*

In the new distribution of the species composing the genus Laurus of Linnæus, the sassafras tree has been made the type of a distinct genus, denominated *Sassafras*, which is recognised by the U. S. and Br. Pharmacopœias.

SASSAFRAS. *Sex. Syst.* Enneandria Monogynia. — *Nat. Ord.* Lauraceæ.

Gen. Ch. Dicœcious. *Calyx* six-parted, membranous; segments equal, permanent at the base. MALES. *Fertile stamens* nine, in three rows, the three inner with double stalked distinct glands at the base. *Anthers* linear, four-celled, all looking inwards. FEMALES, with as many sterile stamens as the males or fewer; the inner often confluent. *Fruit* succulent, placed on the thick fleshy apex of the peduncle, and seated in the torn unchanged calyx. (*Lindley.*)

Sassafras officinale. Nees, *Laurin.* 488. — *Laurus Sassafras.* Willd. *Sp. Plant.* ii. 485; Bigelow, *Am. Med. Bot.* iii. 142; Michaux, *N. Am. Sylv.* ii. 144. This is an indigenous tree of middling size, rising in favourable situations from thirty to fifty feet, with a trunk about a foot in diameter. In the Southern States it is sometimes larger, and in the northern parts of New England is little more than a shrub. The bark of the stem and large branches is rough, deeply furrowed, and grayish; that of the extreme branches or twigs is smooth and beautifully green. The leaves, which are alternate, petiolate, and downy when young, vary much in their form and size even upon the same tree. Some are oval and entire, others have a lobe on one side; but the greater number are three-lobed. Their mean length is four or five inches. The flowers, which are frequently dicœcious, and appear before the leaves, are small, of a pale greenish-yellow colour, and disposed in racemes which arise from the branches below the leaves, and have linear bractes at their base. The corolla is divided into six

* The following is a formula recommended by Hancock. "Take of Rio Negro sarsa, bruised, 2lb.; bark of guaiac, powdered, 8oz.; raspings of guaiac wood, anise seeds, and liquorice root, each 4oz.; mezereon, *bark of the root*, 2oz.; treacle [molasses], 2lb.; and a dozen bruised cloves; pour upon these ingredients about four gallons of boiling water, and shake the vessel thrice a day. When fermentation has well begun, it is fit for use, and may be taken in the dose of a small tumblerful twice or thrice a day." This formula is worthy of attention; but the bark of guaiacum, which is not kept in the shops, might be omitted, or replaced by the wood.

oblong segments. The male flowers have nine stamens; the hermaphrodite, which are on a different plant, have only six, with a simple style. The fruit is an oval drupe, about as large as a pea, of a deep-blue colour when ripe, and supported on a red pedicel, enlarged at the extremity into a cup for its reception.

The sassafras is common throughout the United States, and extends into Mexico. It is said also to grow in Brazil and Cochin-China; but the plants observed in these countries are probably not of the same species. In the United States the sassafras is found both in woods and open places, and is apt to spring up in the neighbourhood of cultivation, and in neglected or abandoned fields. In Pennsylvania and New York, it blooms in the beginning of May, but much earlier at the South. The fresh flowers have a slightly fragrant odour, and almost all parts of the plant are more or less aromatic. The root is directed by the British Pharmacopœia; the bark of the root, and the pith of the twigs or extreme branches, by that of the U. States. The best time for collecting the pith is after the occurrence of frost in autumn; and the same is the case also with the bark of the root. The root is exported, and is the part chiefly used in British pharmacy. It consists of a brownish-white wood, covered with a spongy bark divisible into layers. The latter portion is by far the most active, and is usually kept separate in our shops.

1. *Sassafras Pith.* This is in slender cylindrical pieces, very light and spongy, with a mucilaginous taste, and in a slight degree the characteristic flavour of the sassafras. It abounds in a gummy matter, which it readily imparts to water, forming a limpid mucilage, which, though ropy and viscid, has much less tenacity than that of gum arabic, and will not answer as a substitute in the suspension of insoluble substances. It differs also from solutions of ordinary gum, in remaining limpid when added to alcohol. This mucilage is much employed as a soothing application in inflammation of the eyes; and forms an agreeable and useful drink in dysenteric, catarrhal, and nephritic diseases. It may be prepared by adding a drachm of the pith to a pint of boiling water.

2. *Bark of Sassafras Root.* As found in the shops, this is usually in small irregular fragments, sometimes invested with a brownish epidermis, sometimes partially or wholly freed from it, of a reddish or rusty cinnamon hue, very brittle, and presenting when freshly broken a lighter colour than that of the exposed surfaces. The living bark is nearly white, but becomes coloured, on exposure, immediately after collection. Its odour is highly fragrant, its taste sweetish and gratefully aromatic. These properties are extracted by water and alcohol. They reside in a volatile oil, which is obtained by distillation. (See *Oleum Sassafras.*) According to Dr. Reinsch, the bark contains a heavy and light volatile oil, camphorous matter, fatty matter, resin, wax, a peculiar principle resembling tannic acid called *sassafrid*, tannic acid, gum, albumen, starch, red colouring matter, lignin, and salts. The sassafrid bears some analogy to cinchonic red, and like it appears to be a derivative of the tannin, which exists in much larger proportion in the fresh than in that long kept. (Procter, *Am. Journ. of Pharm.*, Nov. 1866, p. 490.)

Medical Properties and Uses. The bark of sassafras root is stimulant, and perhaps diaphoretic; though its possession of any peculiar tendency to the skin, independently of its mere excitant property, is very doubtful. It is used almost exclusively as an adjuvant to other more efficient medicines, the flavour of which it improves; while it renders them more cordial to the stomach. The complaints for which it has been particularly recommended are chronic rheumatism, cutaneous eruptions, and scorbutic and syphiloid affections. As a remedy in lues venerea, in which it formerly had a high reputation, it is now considered as in itself wholly inefficient. It is most conveniently administered in the form of infusion. The oil may also be given.

Convolvulus Scammonia. Willd. *Sp. Plant.* i. 845; Woodv. *Med. Bot.* p. 243, t. 86; Carson, *Illust. of Med. Bot.* ii. 14, pl. 62. This species of Convolvulus has a perennial, tapering root, from three to four feet long, from nine to twelve inches in circumference, branching towards its lower extremity, covered with a light-gray bark, and containing a milky juice. The stems are numerous, slender, and twining, extending sometimes fifteen or twenty feet upon the ground, or on neighbouring plants, and furnished with smooth, bright-green, arrow-shaped leaves, which stand alternately upon long footstalks. The flowers are placed in pairs, or three together, upon the peduncles, which are round, axillary, solitary, and of nearly twice the length of the leaf. The plant is a native of Syria, Anatolia, and certain islands of the Archipelago. No part is medicinal except the root, which was found by Dr. Russel to be a mild cathartic. It is recognised in the Br. Pharmacopœia, being used for the extraction of resin.* (See *Scammoniæ Resina* in *Part* II.) Scammony is the concrete juice of the fresh root.

Scammony is collected, according to Russel, in the following manner. In the month of June, the earth is cleared away from about the root, the top of which is cut off obliquely about two inches from the origin of the stems. The milky juice which exudes is collected in shells, or other convenient receptacle, placed at the most depending part of the cut surface. A few drachms only are collected from each root. The juice from several plants is put into any convenient vessel, and concretes by time. In this state it constitutes genuine scammony, but is very seldom exported. It is generally prepared for the market by admixture, while it is yet soft, with the expressed juice of the stalks and leaves, with wheat flour, chalk, ashes, fine sand, &c.; and it has been supposed that scammony sometimes consists wholly or in great part of the expressed juice of the root, evaporated to dryness by exposure to the sun, or by artificial heat. According to Landerer, the roots from which the juice has been collected are in some places boiled with water in copper vessels, and the extract added to the juice, not so much with the purpose of adulteration, as under the impression that it favourably modifies the action of the drug. Scammony is exported chiefly from Smyrna,

* Not having had an opportunity of examining the root of the scammony plant, we give the following description by Dr. Otto Borg, Professor in Berlin, contained in Buchner's *Neues Repertorium* of 1864 (xiii. no. 10, p. 448).

The dried root, as it occurs in commerce, is in cylindrical pieces a foot or more in length, about three-fourths of an inch thick, of a pure brown externally, wrinkled in drying, with here and there slender branches, with a head at top, and at the lower end with the cut surface coarsely fibrous; the head being sometimes provided with remains of the stems from half a line to two lines thick. The surface when the root is cut transversely is roundish or rarely elliptical, and pale-brown within. The bark of the root is thin, of a dirty whiteness with dark resinous points. The wood consists of compressed, generally separate, pale-brown, coarsely porous, usually subdivided fibres, parted by a parenchyma similar to the bark. (*Note to the thirteenth edition.*)

though small quantities are said to be sent out of the country at Alexandretta, the seaport of Aleppo. Dr. Pereira was informed by a merchant who had resided in Smyrna, that it is brought upon camels in a soft state into that city, and afterwards adulterated by individuals called scammony makers. The adulteration appears to be conducted in conformity with a certain understood scale, more or less foreign matter being added according to the price. The materials employed are chiefly chalk and some kind of flour or meal. Very little comparatively is exported perfectly pure. We obtain scammony either directly from Smyrna, or indirectly through some of the Mediterranean ports.*

The name of *Aleppo scammony* was formerly given to the better kinds of the drug, and of *Smyrna scammony* to those of inferior quality; the distinction having probably originated in some difference in the character of the scammony obtained at these two places. But no such difference now exists; as scammony is brought from Smyrna of every degree of purity. It has been customary in this country to designate the genuine drug of whatever quality as Aleppo scammony; while the name of Smyrna scammony has been given to a spurious article manufactured in the south of France, and to other factitious substitutes. It is quite time that these terms should be altogether abandoned. We shall treat of the drug under the heads of genuine and factitious scammony.

* An interesting account of the collection and preparation of scammony in Anatolia, in the vicinity of Smyrna, has been communicated by Mr. S. H. Maltass to the *London Pharmaceutical Journ. and Trans.* (xiii. 264). The juice is collected in the same manner as described by Russel in reference to Syria. The product, however, of each plant is somewhat less. In some districts, according to Maltass, ten plants produce only a drachm of scammony; in others the average from each root is a drachm; and in a good soil a plant four years old will yield two drachms. The juice received in the shells is mixed with another portion scraped from the cut surface of the root; and this mixture is the pure or *lachryma scammony*. Only a small quantity of this is taken to Smyrna; the greater part being adulterated by the peasants before it reaches the markets. Sometimes the juice is worked up with a decoction of the roots, in which case it is black, heavier than the preceding, and not so easily broken. Sometimes they add a calcareous earth, in a proportion varying from 10 to 150 per cent. The kind thus prepared is usually kept for some time in Smyrna, and is apt to ferment, so as to become porous and lose its gloss. It is in irregular lumps, and is the kind usually sold in London as *lachryma scammony*. Another kind sold in London in rough lumps, and probably under the same name, is prepared in the interior of the country by mixing the juice with wheat starch, ashes, earthy matters, gum arabic or tragacanth, and sometimes wax, yelk of egg, pounded scammony roots and leaves, flour, or resin. A kind much used in Great Britain is prepared by the Jews in Smyrna, and is in the form of cakes as described in the text. It is of two qualities. The *first quality* is prepared by mixing *skilip* (which is an inferior kind of scammony prepared at Anjora, and consists of from 30 to 40 per cent. of juice and 60 to 70 of starch) with 60 per cent. of inferior scammony from the neighbourhood of Smyrna; the *second quality*, by mixing *skilip* with about 30 per cent. of the latter kind, and adding about 10 per cent. of gum arabic and blacklead. The *first quality* contains about 50 per cent. of resin, the *second* about 30 per cent. For an account of specimens of scammony sent by Mr. Maltass from Smyrna, see a paper by Mr. D. Hanbury in the *Pharm. Journ.* (xiii. 268).—*Note to the tenth edition.*

Prof. Ch. Boulier, of Algiers, gives the following account of the collection of scammony in the northwestern parts of Anatolia. The plant is not cultivated, but grows wild in rocky places covered with brushwood. At the flowering period, about the end of June and beginning of July, the peasants go forth in search of localities among the mountains where it is most abundant, and, having satisfied themselves on this point, return home, provide themselves with the requisite implements, and set out for the place of collection. Clearing away the brushwood and stems, the peasant digs deeply around the root, then cuts off the top obliquely, and affixes a muscle shell to the root so as to receive the juice as it flows from the dependent part. He then passes on to other plants upon which he operates in like manner. After a time he returns upon his steps, and empties the shells successively into a tinned copper vessel. Next day he goes over the same ground, and scrapes by a knife from the cut surface the juice which has in the mean time flowed out, and partially concreted. This he mixes with that previously collected, and, when his vessel is full, takes it to some neighbouring market, where it is bought up, and sent to the wholesale druggists at Constantinople and Smyrna. The juice reaches the market in a pasty state, and whitish like cheese except where exposed to the air. It is in these centres of trade, or on its way from the collectors, that the drug undergoes the various sophistications to which it is subjected; the peasant himself being honest, and seldom disposed to adulterate. (*Ibid.*, April, 1860, p. 521.)—*Note to the twelfth edition.*

Genuine Scammony. This is sent into commerce in drums or boxes, and is either in irregular lumps, in large solid masses of the shape of the containing vessel into which it appears to have been introduced while yet soft, or in circular, flattish or plano-convex cakes. It seldom reaches us in an unmixed state. Formerly small portions of pure scammony were occasionally to be met with in Europe, contained in the shells in which the juice was collected and dried. This variety, denominated *scammony in shells*, is now scarcely to be found. The pure drug is called *virgin scammony*. It is in irregular pieces, often covered with a whitish-gray powder, friable and easily broken into small fragments between the fingers, with a shining grayish-green fracture soon passing into greenish-black, and exhibiting under the microscope minute air-cells, and numerous gray semi-transparent splinters.* It is easily pulverized, affording a pale ash-gray powder. When rubbed with water it readily forms a milky emulsion. It has a rather strong, peculiar odour, compared to that of old cheese. The taste is feeble at first, and afterwards somewhat acrid, but without bitterness. It gives no evidence, when the requisite tests are applied, of the presence of starch or carbonate of lime, leaves but a slight residue when burned, and yields about 80 per cent. of its weight to ether. Considerable quantities of what is called virgin scammony have been imported into this country since the drug-law went into operation; but, though some specimens are tolerably pure, on the whole the drug falls far short of the proper standard. Dr. E. R. Squibb examined many specimens, and found the proportion of resin to vary from 25 to 79·7 per cent.; only two or three, out of more than 30 examined, approaching the latter degree of purity within 10 per cent. (*Am. Journ. of Pharm.*, Jan. 1863, p. 51.)†

The form of scammony chiefly found in our markets is that in circular cakes. These are sometimes flattish on both sides, but generally somewhat convex on one side and flat on the other, as if dried in a saucer, or other shallow vessel. They are from four to six inches in diameter, and from half an inch to an inch and a half, or even two inches thick in the centre. As found in the retail shops, they are often in fragments. They are hard and heavy, with a faintly shining roughish fracture; and when broken exhibit in general a structure very finely porous, sometimes almost compact, and in a very few instances cavernous. Their colour externally is a dark-ash or dark-olive, or slate colour approaching to black; internally somewhat lighter and grayish, with an occasional tinge of green or yellow, but deepening by exposure. The small fragments are sometimes slightly translucent at the edges. The mass, though hard, is pulverizable without great difficulty, and affords a light-gray powder. It imparts to water with which it is triturated a greenish milky appearance. The smell is rather disagreeable, and similar to that of the pure drug. The taste, very slight at first, becomes feebly bitterish and acrid. This kind of scammony is never quite pure, and much of it is considerably adulterated. In some of the cakes carbonate of lime is the chief impurity; in others the adulterating substance is probably meal, as evidences of the presence of starch and lignin are afforded; and in others again both these substances are found. Christison discovered in the chalky specimens from 15 to 38 per cent. of carbonate of lime; in the amylaceous, from 13 to 42 per cent. of impurity. It was probably to the flat, dark-coloured, compact, difficultly pulverizable, and more impure cakes that the name of

* According to Maltass, the purest scammony has a reddish-black fracture, unless it has been mixed with water in its preparation, in which case it is black and very glossy (*Pharm. Journ.*, xiii. 266.)

† Dr. Squibb gives the following description of the drug recently imported as *virgin scammony*. "It generally occurs in soldered square tin boxes, containing 25 to 28 pounds each. Occasionally, however, it is in round wooden boxes or drums of a similar capacity. The scammony is in irregular, rough and fissured masses of various sizes, sometimes porous, but commonly solid, hard, and semi-resinous, having a tough, dull fracture. It is of a very dark grayish-green colour internally, often nearly black, but more of an ash colour externally. It is rarely dry enough to be pulverulent, yet still more rarely too moist to be rubbed into coarse powder, and it generally loses 6 per cent. in drying sufficiently to make a fine powder." (*Am. Journ. of Pharm.*, Jan. 1863, p. 49.)—*Note to the twelfth edition.*

Smyrna scammony was formerly given. These have been erroneously ascribed by some to *Periploca Secamone*, a plant growing in Egypt.*

Scammony is ranked among the gum-resins. It is partially dissolved by water, much more largely by alcohol and ether, and almost entirely, when pure, by boiling diluted alcohol. Its active ingredient is resin, which constitutes from 80 to 90 per cent. of pure dry scammony. (See *Resina Scammonii*.) The gum-resin has been analyzed by various chemists, but the results are uncertain; as the character of the specimens examined is insufficiently determined by the terms Aleppo and Smyrna scammony, employed to designate them. Thus, Bouillon-Lagrange and Vogel obtained, from 100 parts of Aleppo scammony, 60 of resin, 3 of gum, 2 of extractive, and 35 of insoluble matter; from the same quantity of Smyrna scammony, 29 parts of resin, 8 of gum, 5 of extractive, and 58 of vegetable remains and earthy substances. It is obvious that both the specimens upon which they operated were very impure. Marquart found in pure scammony (*scammony in shells*) 81·25 per cent. of resin, 3·00 of gum with salts, 0·75 of wax, 4·50 of extractive, 1·75 of starchy envelopes, bassorin, and gluten, 1·50 of albumen and lignin, 3·75 of ferruginous alumina, chalk, and carbonate of magnesia, and 3·50 of sand. Christison found different specimens of pure scammony to contain, in 100 parts, from 77 to 83 parts of resin, from 6 to 8 of gum, from 3·2 to 5 of lignin and sand, and from 7·2 to 12·6 of water, with occasionally a little starch, probably derived accidentally from the root, and not in sufficient quantity to cause a cold decoction of the gum-resin to give a blue colour with iodine. Mr. Hanbury, of London, found 91·1 per cent. of resin in the purest scammony in shells; and Mr. B. W. Bull, of New York, 86·88 per cent. in a specimen in irregular lumps, received from Constantinople as Aleppo Scammony. (*N. Y. Journ. of Pharm.*, June, 1852.) As already

* Dr. Pereira, in his work on Materia Medica, describes as follows the varieties of scammony as they exist in the London market.

1. *Virgin Scammony. Pure Scammony. Lachryma Scammony.* The description of this corresponds with that of pure scammony given in the text. In addition, the following particulars may be mentioned. The whitish powder often found upon the surface effervesces with muriatic acid, and consists of chalk, in which the lumps have probably been rolled. The sp. gr. of the masses is 1·210. In the same pieces it sometimes happens that certain portions are shining and black, while others are dull-grayish. Virgin scammony readily takes fire, and burns with a yellowish flame. This variety is now much more abundant in the shops of London than formerly.

2. *Scammony of second quality.* This is called *seconds* in commerce. It is in two forms. 1. In *irregular pieces.* This, in external appearance, brittleness, odour, and taste, resembles virgin scammony; but is distinguished by its greater sp. gr., which is 1·463, by its dull, very slightly shining fracture, and its grayish colour. The freshly broken surface effervesces with muriatic acid, but the cold decoction does not give a blue colour with iodine. It therefore contains chalk, but not fecula. 2. In *large regular masses.* This has the form of the drum or box in which it was imported, and into which it was probably introduced while soft. It has a dull grayish fracture, and the sp. gr. 1·359. It exhibits, with the appropriate tests, evidence of the presence both of chalk and fecula. It is sometimes found of a soft or cheesy consistence.

3. *Scammony of third quality.* This is called *thirds* in commerce. It is in circular, flat cakes, about five inches in diameter and one inch thick. The cakes are dense, heavy, and more difficult to break than the preceding varieties. The fracture is sometimes resinous and shining, sometimes dull, and exhibits air cavities, and numerous white specks, which consist of chalk. The colour is grayish or grayish-black. The sp. gr. varies from 1·276 to 1·543. Both chalk and flour are detected by tests. In five different cakes, the quantity of chalk employed in the adulteration was stated by the importer to be, in 100 parts of the cakes respectively, 13·07, 23·1, 25·0, 31·05, and 37·54, numbers which correspond very closely, in the two extremes, with the results obtained by Christison. This is the variety of scammony referred to in the text as the one chiefly used in the United States.

A valuable paper by Dr. Carson, on the varieties of scammony imported into this country, was published in the *Am. Journ. of Pharm.* (xx. i.), to which the reader is referred. Besides the kinds described in the text, namely the virgin scammony, and those which are adulterated with chalk or meal or both, Dr. Carson describes two, under the names of *gummy* and *black gummy* scammony, in which the chief adulteration appears to be tragacanth, or some analogous substance, which is associated in the dark variety with bone-black. They afforded from 6 to 13 per cent. of resin. They are in circular cakes, hard, compact, of difficult pulverization, and viscid when moistened. (*Note to the eighth edition.*)

stated, scammony is seldom quite pure as found in our shops. Much of it contains not more than 50 per cent. of the resin, some not more than 42 per cent., and the worst varieties as little as 10 per cent., or even less.* Sometimes the cakes are of good quality on the outside, and inferior within. (Bull, *N. Y. Journ. of Pharm.*, i. 7.) It has been suggested, in this uncertainty as to the strength of the scammony of the shops, whether it might not be best to abandon its internal use altogether, and to employ only the resin, which is of uniform strength. Indeed, the resin has been officinally substituted for the gum-resin in that important preparation, the compound extract of colocynth.

In the U. S. Pharmacopœia it is directed that 75 per cent. of the drug should be soluble in ether, in the British from 80 to 90 per cent Both require that it should not effervesce with muriatic acid, and that water heated with it should not give a blue colour with tincture of iodine; the former test indicating the absence of chalk, the latter of farinaceous matters.

Factitious Scammony. Montpellier Scammony. Much spurious scammony is manufactured in the south of France, said by Guibourt to be made from the expressed juice of *Cynanchum Monspeliacum*, incorporated with various resins, and other purgative substances. M. Thorel, however, a pharmaceutist of Avallon, denies that this plant is employed in its preparation. (*Journ. de Pharm.*, xx. 107.) It has been occasionally imported into the United States, and sold as Smyrna scammony. It is usually in flat semicircular cakes, four or five inches in diameter, and six or eight lines thick, blackish both externally and within, very hard, compact, rather heavy, of a somewhat shining and resinous fracture, a feeble balsamic odour wholly different from that of genuine scammony, and a very bitter nauseous taste. When rubbed with the moistened finger it becomes dark-gray, unctuous, and tenacious. We have seen another substance sold as Smyrna scammony, which was obviously spurious, consisting of blackish, circular, flat cakes, or fragments of such cakes, rather more than half an inch thick, very light, penetrated with small holes, as if worm-eaten, and when broken exhibiting an irregular, cellular, spongy texture. Dr. Pereira described a factitious substance sold as *Smyrna scammony*, which was in circular flat cakes about half an inch thick, blackish, and of a slaty aspect, breaking with difficulty, of a dull black fracture, and of the sp. gr. 1·412. Moistened and rubbed it had the smell of guaiac, which could also be detected by chemical tests.

Medical Properties and Uses. Scammony is an energetic cathartic, apt to occasion griping, and sometimes operating with harshness. It was known to the ancient Greek physicians, and was much employed by the Arabians, who not only gave it as a purgative, but also applied it externally for the cure of various cutaneous diseases. It may be used in all cases of torpid bowels, when a powerful impression is desired; but, on account of its occasional violence, it is seldom administered, except in combination with other cathartics, the action of which it promotes, while its own harshness is mitigated. It should be given in emulsion with mucilage, sugar, almonds, liquorice, or other demulcent; and its disposition to gripe may be counteracted by the addition of an aromatic. The dose is from five to fifteen grains of pure scammony, from ten to thirty of that commonly found in the market.

Squill.

The bulb of Scilla maritima. *U. S.* The sliced and dried bulb of Urginea Scilla, *Steinheil. Br.*

Scille, *Fr.;* Meerzwiebel, *Germ.;* Scilla, *Ital.;* Cebolla, albarrana, *Span.*

Scilla. *Sex. Syst.* Hexandria Monogynia. — *Nat. Ord.* Liliaceæ.

Gen. Ch. Corolla six-petaled, spreading, deciduous. *Filaments* thread-like. *Willd.*

Scilla maritima. Willd. *Sp. Plant.* ii. 125; Woodv. *Med. Bot.* p. 745, t. 255 — *Squilla maritima.* Lindley, *Flor. Med.* p. 591; Carson, *Illust. of Med. Bot.* ii. 46, pl. 89. This is a perennial plant, with fibrous roots proceeding from the bottom of a large bulb, which sends forth several long, lanceolate, pointed, somewhat undulated, shining, deep-green leaves. From the midst of the leaves a round, smooth, succulent flower-stem rises, from one to three feet high, terminating in a long, close spike of whitish flowers. These are destitute of calyx, and stand on purplish peduncles, at the base of each of which is a linear, twisted, deciduous floral leaf. The squill grows on the sea-coast of Spain, France, Italy, Greece, and the other countries bordering on the Mediterranean. The bulb is the officinal portion. It is generally dried for use; but is sometimes imported into this country in the recent state packed in sand.

Properties. The fresh bulb is pear-shaped, usually larger than a man's fist, sometimes as large as the head of a child, and consists of fleshy scales attenuated at their edges, closely applied over each other, and invested by exterior scales so thin and dry as to appear to constitute a membranous coat. There are two varieties, distinguished as the *red* and *white squill.* In the former, the exterior coating is of a deep reddish-brown colour, and the inner scales have a whitish rosy or very light pink epidermis, with a yellowish-white parenchyma; in the latter, the whole bulb is white. They do not differ in medicinal virtue. The bulb abounds in a viscid, very acrid juice, which causes it to inflame and even excoriate the skin when much handled. By drying, this acrimony is very much diminished, with little loss of medicinal power. The bulb loses about four-fifths of its weight in the process. Vogel found 100 parts of fresh squill to be reduced to 18 by desiccation. The process is somewhat difficult, in consequence of the abundance and viscidity of the juice. The bulb is cut into thin transverse slices, and the pieces dried separately by artificial or solar heat. The outer and central scales are rejected, the former being dry and destitute of activity, the latter too fleshy and mucilaginous.

Dried squill, as found in our shops, is in irregular oblong pieces, often more or less contorted, of a dull yellowish-white colour with a reddish or rosy tint, sometimes entirely white, slightly diaphanous, brittle and pulverizable when perfectly dry, but often flexible from the presence of moisture, for which they have a great affinity. Occasionally a parcel will be found consisting of vertical slices, some of which adhere together at the base. The odour is very feeble, the taste bitter, nauseous, and acrid.

The virtues of squill are extracted by water, alcohol, and vinegar. It was analyzed by Vogel; and, more recently (A. D. 1856), by M. J. H. Marais, who found, in 100 parts, 30 of mucilage, 15 of sugar, 8 of tannin, 10 of a red, acid colouring matter, 2 of a yellow, acid, odorous colouring matter, 1 of fatty matter, 1 of *scillitin*, 5 of salts, and traces of iodine. (*Journ. de Pharm.*, Fév. 1857, p. 127.) Examined by the microscope, the bulb is seen to be pervaded by innumerable minute acicular crystals, consisting of the salts of squill, chiefly, according to M. Marais, carbonate of lime, with a little chloride of calcium. (*Ibid.*) Water distilled from it had neither taste nor smell, and was drunk by Vogel to the amount of six ounces without effect. The acrid principle, therefore, is not volatile. The substance named *scillitin* by Vogel was soluble in water, alcohol, and vinegar; but was considered by M. Tilloy, of Dijon, to be

a compound of the proper active principle of squill with gum and uncrystallizable sugar. The *scillitin*, obtained by the latter experimenter, was insoluble in water and dilute acids, soluble in alcohol, exceedingly acrid and bitter, and very powerful in its influence on the system. A single grain produced the death of a strong dog. The process of Tilloy may be seen in former editions of this work. The scillitin obtained by him was still impure. Labourdais believed that he had obtained it in an isolated state by means of animal charcoal. A decoction of squill was first treated with acetate of lead to separate the viscid matters, was then filtered and agitated in the cold with purified animal charcoal in fine powder, and afterwards allowed to rest. The charcoal gradually subsided, carrying with it the bitter and colouring principles. The liquid being decanted, the solid matter was dried, and treated with hot alcohol, which acquired an insupportable bitterness. The alcohol, being distilled off, left a milky liquid, which was allowed to evaporate spontaneously. The scillitin thus procured was solid, uncrystallized, easily decomposable by heat, almost caustic to the taste, not deliquescent, neuter, but slightly soluble in water, to which, however, it imparted a very great bitterness, very soluble in alcohol, and dissolved, but at the same time decomposed by concentrated sulphuric and nitric acids, imparting to the former a purple colour, instantly becoming black. (*Ann. de Thérap.*, 1849, p. 145.) L. F. Bley succeeded in obtaining scillitin, by the process of Labourdais, in long flexible needle-shaped crystals, by simply allowing the last alcoholic solution to evaporate spontaneously. (*Arch. der Pharm.*, lxi. 141.) Landerer obtained a crystalline principle from fresh squill, by treating the bruised bulb with dilute sulphuric acid, concentrating the solution, neutralizing it with lime, drying the precipitate, exhausting this with alcohol, and evaporating the tincture, which, on cooling, deposited the substance in question in prismatic crystals. It was bitter, but not acrid, insoluble in water or the volatile oils, slightly soluble in alcohol, and, according to Landerer, capable of neutralizing the acids. (*Christison's Dispensatory.*) Wittstein inferred from his experiments that the bitterness and acrimony of squill reside in distinct principles. (See *Pharm. Journ.*, x. 359.) By a more recent analysis, Tilloy was induced to believe that there were two active principles in squill; one a resinoid substance very acrid and poisonous, soluble in alcohol and not in ether, the other a very bitter principle, yellow, and soluble in water and alcohol. The acrid principle, in the dose of about three-quarters of a grain, killed a dog. The bitter principle is much less powerful. Both are contained in the matters extracted from squill by means of animal charcoal. (*Journ. de Pharm.*, xxiii. 410.)

M. Marais obtained results somewhat different from those of his predecessors. The *scillitin* procured by him is uncrystallizable, hygrometric but not deliquescent, insoluble in water, and very soluble in alcohol and ether, even cold. It is in minute semitransparent spangles, of a pale-yellow colour, and of an intense, pungent bitterness, which is increased by the presence of water. Sulphuric acid dissolves it, producing a colour precisely similar to that which the same acid causes with cod-liver oil. Nitric acid also dissolves it, causing a bright-red colour, which rapidly disappears. Muriatic acid has no effect on it. The hydrated alkalies disengage ammonia, showing that it contains nitrogen. Ammonia and potassa do not dissolve it, but remove its bitterness. Tannic acid gives with it a pale-yellow precipitate. It approaches the alkaloids in character; as it has an alkaline reaction, combines with acetic acid, and contains nitrogen. In its effects on the system, it resembles the acrid narcotics, proving fatal in the dose of three-quarters of a grain. It first vomits and purges violently, then acts as a narcotic, and finally paralyzes the heart. In fatal doses it occasions violent inflammation of the alimentary canal. Applied endermically, it acts much more rapidly than by the mouth, and now almost exclusively as a narcotic. A vigorous dog was killed in twenty-two minutes by six-tenths of a grain applied in this way. M. Marais obtains it by making a concentrated tincture of dry squill with alcohol of 0·56, precipitating with milk of lime, shaking the whole with ether, decanting the supernatant liquid, wash-

ing the magma with a fresh portion of ether till wholly deprived of bitterness, uniting the liquors, and distilling until there remains in the retort only alcohol with the scillitin and a little fatty matter. This is then evaporated as quickly as possible with a gentle heat, and the residue treated with alcohol of 0·90, which dissolves the scillitin, and leaves the fatty matter. The alcoholic solution, evaporated to dryness, yields the scillitin, which is to be immediately enclosed in a well-stopped bottle. (*Ibid.*, xxi. 128, Fév. 1857.)

When kept in a dry place, squill retains its virtues for a long time; but if exposed to moisture it soon becomes mouldy.

Medical Properties and Uses. Squill is expectorant, diuretic, and in large doses emetic and purgative. In overdoses it has been known to occasion hypercatharsis, strangury, bloody urine, and fatal inflammation of the stomach and bowels. The Greek physicians employed it as a medicine; and it has retained to the present period a deserved popularity. As an expectorant, it is used both in cases of deficient and of superabundant secretion from the bronchial mucous membrane; in the former case usually combined with tartar emetic or ipecacuanha, in the latter frequently with the stimulant expectorants. In both instances, it operates by stimulating the vessels of the lungs; and, where the inflammatory action in this organ is considerable, as in pneumonia and severe catarrh, the use of squill should be preceded by depletory measures. In dropsical diseases it is very much employed, especially in connection with calomel, which is supposed to excite absorption, while the squill increases the secretory action of the kidneys. It is thought to succeed best in these complaints, in the absence of general inflammatory excitement. A remarkable case of greatly enlarged spleen, which was entirely removed under the use of fifteen drops of tincture of squill, given five times a day, and operating as a diuretic, is recorded by Dr. Hennigké in the Medical Gazette of Strasburg. The cure was effected in three weeks. (*Ann. de Thérap.*, 1867, p. 91.) On account of its great uncertainty and occasional harshness, it is very seldom prescribed as an emetic, except in infantile croup or catarrh, in which it is usually given in the form of syrup or oxymel. When given in substance it is most conveniently administered in the form of pill. The dose, as a diuretic or expectorant, is one or two grains repeated two or three times a day, and gradually increased till it produces slight nausea, or evinces its action upon the kidneys or lungs. From six to twelve grains will generally vomit. The vinegar and syrup of squill are officinal, and are much used. An *acetic extract* has been prepared by Mr. F. D. Niblett, by digesting a pound of squill with three fluidounces of acetic acid and a pint of distilled water, with a gentle heat, for forty-eight hours, then expressing, and, without filtration, evaporating to a proper consistence. One grain is equal to about three of the powder. (*Pharm. Journ.*, xii. 133.)

Gen. Ch. Calyx bilabiate, upper lip generally entire, lower somewhat three-toothed. *Vexillum* ovate, broad. *Carina* very obtuse, enclosing the stamens and pistils. *Stamens* monadelphous. *Legume* plano-compressed, many-seeded, not glandular. (*De Cand.*)

Cytisus Scoparius. De Cand. *Prodrom.* ii. 154. — *Spartium Scoparium.* Willd. *Sp. Plant.* iii. 933; Woodv. *Med. Bot.* p. 413, t. 150. This is a common

European shrub, cultivated in our gardens, from three to eight feet high, with numerous straight, pentangular, bright-green, very flexible branches, and small, oblong, downy leaves, usually ternate, but on the upper part of the plant sometimes simple. The flowers are numerous, papilionaceous, large, showy, of a golden-yellow colour, and solitary upon short axillary peduncles. The seeds are contained in a compressed legume, which is hairy at the sutures.

The whole plant has a bitter nauseous taste, and, when bruised, a strong peculiar odour. The tops of the branches are the officinal portion; but the seeds also are used, and, while they possess similar virtues, have the advantage of keeping better. Water and alcohol extract their active properties. According to Cadet de Gassicourt, the flowers contain volatile oil, fatty matter, wax, chlorophyll, yellow colouring matter, tannin, a sweet substance, mucilage, osmazome, albumen, and lignin. Dr. Stenhouse has separated from them two principles, one of which, called *scoparin*, he believes to be the diuretic principle, and the other, named *spartein*, to be narcotic. The former is in stellate crystals, easily dissolved by boiling water and alcohol, and is obtained by purifying a yellow gelatinous substance deposited upon the evaporation of the decoction. It may be given in the dose of four or five grains. The latter was obtained by distillation from the mother-waters of the scoparin. It is a colourless liquid, having a peculiar bitter taste, and all the properties of a volatile organic base. It appears to have narcotic properties. But we need more definite information on the subject. (*Annuaire de Thérap.*, 1853, p. 153.)

Medical Properties and Uses. Broom is diuretic and cathartic, and in large doses emetic, and has been employed with great advantage in dropsical complaints, in which it was recommended by Mead, Cullen, and others. Cullen prescribed it in the form of decoction, made by boiling half an ounce of the fresh tops in a pint of water down to half a pint, of which he gave a fluidounce every hour till it operated by stool or urine. It is a domestic remedy in Great Britain, but is seldom used in this country. The seeds may be given in powder, in the dose of ten or fifteen grains.

SCUTELLARIA. *U. S. Secondary.*

Scullcap.

The herb of Scutellaria lateriflora. *U. S.*

Scutellaria. *Sex. Syst.* Didynamia Gymnospermia. — *Nat. Ord.* Labiatæ. *Gen. Ch. Calyx* bilabiate; lips entire; mouth closed by a helmet-shaped lid after the corolla falls. *Corolla* bilabiate, upper lip vaulted, lower dilated, convex; tube of the corolla bent.

Several species of Scutellaria have attracted attention. *Scutellaria galericulata*, or common *European scullcap*, which also grows wild in this country, has a feeble, somewhat alliaceous odour, and a bitterish taste. It has been employed in intermittents, and externally in old ulcers. Dr. R. W. Evans, of Canada West, has found it useful in epilepsy; but to effect a cure it must be continued, he says, for five or six months. He makes an infusion with two ounces of the herb and eight ounces of water, and gives a fluidounce every eight hours, doubling the quantity after a week. (See *Am. Journ. of Med. Sci.*, xvii. 495.) Another indigenous species, the *S. integrifolia*, of which *S. hyssopifolia*, Linn, is considered by some as a variety, is intensely bitter, and might probably be found useful as a tonic. S. lateriflora is the only officinal species.

Scutellaria lateriflora. Willd. *Sp. Plant.* iii. 172; Gray, *Manual of the Bot. of North. U. S.*, p. 315. This is an indigenous perennial herb, with a stem erect, much branched, quadrangular, smooth, and one or two feet high. The leaves are ovate, acute, dentate, subcordate upon the stem, opposite, and supported upon long petioles. The flowers are small, of a pale-blue colour, and disposed in long, lateral, leafy racemes. The tube of the corolla is elongated, the upper

lip concave and entire, the lower three-lobed. The plant grows in moist places by the sides of ditches and ponds in all parts of the Union.

To the senses scullcap does not indicate, by any peculiar taste or smell, the possession of medicinal virtues. It is even destitute of the aromatic properties which are found in many of the labiate plants. When taken internally, it produces no very obvious effects. Notwithstanding this apparent inertness, it obtained, at one period, extraordinary credit throughout the United States, as a preventive of hydrophobia, and was even thought to be useful in the disease itself. A strong infusion of the plant was given in the dose of a teacupful, repeated several times a day, and continued for three or four months after the bite was received; while the herb itself was applied to the wound. Strong testimony was adduced in favour of its prophylactic powers; but it has already shared the fate, which in this case is no doubt deserved, of numerous other specifics against hydrophobia, which have been brought into temporary popularity, only to be speedily abandoned. Nevertheless, it is thought by some practitioners to have valuable therapeutic properties; and Drs. Ariel Hunton and C. H. Cleaveland, of Vermont, speak in strong terms of its efficacy as a nervine. They have employed it in neuralgic and convulsive affections, chorea, delirium tremens, and nervous exhaustion from fatigue or over-excitement, and have found it highly advantageous. Dr. Cleaveland says that he prefers it to all other nervines or antispasmodics, except where an immediate effect is desirable. He prefers the form of infusion, which he prepares by adding half an ounce of the dried leaves to a teacupful of water, and allows the patient to drink *ad libitum.* (*Am. Journ. of Pharm.*, xxiii. 370; also *N. J. Med. Reporter*, v. 13.)

Two preparations are now used; one called *scutellarine*, though erroneously, as it has no claim to be considered a pure proximate principle, the other a *fluid extract.* The so-called scutellarine is prepared by mixing a concentrated tincture with water, precipitating by alum, and then washing and drying. Dr. Cleaveland gives it in a dose varying from one to three or four grains, and finds very happy effects from it in quieting nervous disorders. (*N. J. Med. Reporter*, viii. 121.) The fluid extract, prepared by the Messrs. Tilden, is used in the dose of one or two fluidrachms. Dr. Joseph Bates, of New Lebanon, N. Y., speaks highly of it as a nervine. (*Bost. Med. and S. Journ.*, lii. 337.) W.

SENEGA. *U. S.*

Seneka.

The root of Polygala Senega. *U. S.*

Off. Syn. SENEGÆ RADIX. *Senega Root.* The dried root of Polygala Senega. *Br.*

Polygale de Virginie, *Fr.;* Klapperschlangenwurzel, *Germ.*; Poligala Virginiana, *Ital.*

POLYGALA. *Sex. Syst.* Diadelphia Octandria.—*Nat. Ord.* Polygalaceæ.

Gen. Ch. Calyx five-leaved, with two leaflets wing-shaped and coloured. *Legume* obcordate, two-celled. *Willd.*

Besides *P. Senega*, two other species have attracted some attention in Europe —*P. amara* and *P. vulgaris*—as remedies in chronic pectoral affections; but as they are not natives of this country, and are never used by practitioners here, they do not merit particular notice.

Polygala Senega. Willd. *Sp. Plant.* iii. 894; Bigelow, *Am. Med. Bot.* ii. 97; Barton, *Med. Bot.* ii. 111. This unostentatious plant has a perennial branching root, from which several erect, simple, smooth, round, leafy stems annually rise, from nine inches to a foot in height. The stems are occasionally tinged with red or purple below, but are green near the top. The leaves are alternate or scattered, lanceolate, pointed, smooth, bright-green on the upper surface, paler beneath, and sessile or supported on very short footstalks. The flowers are small and white, and form a close spike at the summit of the stem. The calyx is their most conspicuous part. It consists of five leaflets, two of which are wing-shaped, white, and larger than the others. The corolla is small and closed.

The capsules are small, much compressed, obcordate, two-valved and two-celled, with two oblong-ovate, blackish seeds, pointed at one end.

This species of Polygala, commonly called *Seneka snakeroot*, grows wild in all parts of the United States, but most abundantly in the southern and western sections, where the root is collected for sale. It is brought into market in bales weighing from fifty to four hundred pounds.

Properties. As the root occurs in commerce, it is of various sizes, from that of a straw to that of the little finger, presenting a thick knotty head, which exhibits traces of the numerous stems. It is tapering, branched, variously twisted, often marked with crowded annular protuberances, and with a projecting keel-like line, extending along its whole length. The epidermis is corrugated, transversely cracked, of a yellowish-brown colour in the young roots, and brownish-gray in the old. In the smaller branches the colour is a lighter yellow. The bark is hard and resinous, and contains the active principles of the root. The central portion is ligneous, white, and quite inert, and should be rejected in the preparation of the powder. The colour of this is gray. The odour of seneka is peculiar, strong in the fresh root, but faint in the dried. The taste is at first sweetish and mucilaginous, but after chewing becomes somewhat pungent and acrid, leaving a peculiar irritating sensation in the fauces. These properties, as well as the medical virtues of the root, are extracted by boiling water and by alcohol. Diluted alcohol is an excellent solvent. The root has been analyzed by Gehlen, Peschier of Geneva, Feneulle of Cambray, Dulong D'Astafort, Folchi, and Trommsdorff, and more recently by M. Quevenne. The *senegin* of Gehlen, though supposed at one time to be the active principle, has been ascertained to be a complex substance, and to have no just claim to the rank assigned to it. From a comparison of the results obtained by the above-mentioned chemists, it would appear that seneka contains, 1. a peculiar acrid principle, which M. Quevenne considers to be an acid, and has named *polygalic acid;* 2. a yellow colouring matter, of a bitter taste, insoluble or nearly so in water, but soluble in ether and alcohol; 3. a volatile principle considered by some as an essential oil, but thought by Quevenne to possess acid properties, and named by him *virgineic acid;* 4. pectic acid or pectin; 5. tannic acid of the variety which precipitates iron green; 6. gum; 7. albumen; 8. cerin; 9. fixed oil; 10. woody fibre; and 11. saline and earthy substances, as the carbonates, sulphates, and phosphates of lime and potassa, chloride of potassium, alumina, magnesia, silica, and iron. The virtues of seneka appear to reside chiefly, if not exclusively, in the acrid principle which M. Quevenne called polygalic acid, and which he considered closely analogous to saponin. He obtained it pure by the following process. Powdered seneka is exhausted by alcohol of 33°, and so much of the alcohol is distilled off as to bring the resulting tincture to the consistence of syrup. The residue is treated with ether, in order to remove the fatty matter. The liquid upon standing deposits a precipitate, which is separated by filtration, and is then mixed with water. To the turbid solution thus formed alcohol is added, which facilitates the production of a white precipitate, consisting chiefly of polygalic acid. The liquid is allowed to stand for several days, that the precipitate may be fully formed. The supernatant liquid being decanted, the precipitate is drained upon a filter, and, being removed while yet moist, is dissolved by the aid of heat in alcohol of 36°. The solution is boiled with purified animal charcoal, and filtered while hot. Upon cooling it deposits the principle in question in a state of purity. Thus obtained, polygalic acid is a white powder, inodorous, and of a taste at first slight, but soon becoming pungent and acrid, and producing a very painful sensation in the throat. It is fixed, unalterable in the air, inflammable, soluble in water slowly when cold and rapidly with the aid of heat, soluble in all proportions in boiling absolute alcohol, which deposits most of it on cooling, quite insoluble in ether and in the fixed and volatile oils, and possessed of the properties of reddening litmus and neutralizing the alkalies. Its constituents are carbon, hydrogen, and oxygen. M. Quevenne found it, when given to dogs, to occasion vomiting, and much embarrassment in respi-

ration, and in large quantities to destroy life. Dissection exhibited evidences of inflammation of the lungs; and frothy mucus was found in the stomach, œsophagus, and superior portion of the trachea, showing the tendency of this substance to increase the mucous secretion, and explaining in part the beneficial influence of seneka in croup. (*Journ. de Pharm.*, xxii. 449, and xxiii. 227.) M. Bolley confirms the opinion of Quevenne as to the strong analogy between *polygalic acid* or *senegin* and saponin, if not their absolute identity, and considers them both as glucosides, resolvable by muriatic acid into glucose and a peculiar substance called *sapogenin*. He represents the composition of senegin by the formula $C_{36}H_{24}O_{30}$. (See *Am. Journ. of Pharm.*, xxvii. 45.)

From the experiments of M. Quevenne it also appears that seneka yields its virtues to water, cold or hot, and to boiling alcohol; and that the extracts obtained by means of these liquids have the sensible properties of the root. But, under the influence of heat, a portion of the acrid principle unites with the colouring matter and coagulated albumen, and thus becomes insoluble in water; and the decoction, therefore, is not so strong as the infusion, if time is allowed, in the formation of the latter, for the full action of the menstruum. If it be desirable to obtain the virtues of the root in the form of an aqueous extract, the infusion should be prepared on the principle of displacement; as it is thus most concentrated, and consequently requires less heat in its evaporation. In forming an infusion of seneka, the temperature of the water, according to M. Quevenne, should not exceed 104° F.

The roots of *Panax quinquefolium* or ginseng are frequently mixed with the seneka, but are easily distinguishable by their shape and taste. Another root has been occasionally observed in parcels of seneka, supposed to be that of Gillenia trifoliata. This would be readily distinguished by its colour and shape (see *Gillenia*), and by its bitter taste without acrimony. One of the most characteristic marks of seneka is the projecting line running the whole length of the root, and appearing as though a thread were placed beneath the bark, and, being attached at the upper end, were drawn at the lower, so as to give the root a contorted shape.

Medical Properties and Uses. Seneka is a stimulating expectorant and diuretic, and in large doses emetic and cathartic. It appears indeed to excite more or less all the secretions, proving occasionally diaphoretic and emmenagogue, and increasing the flow of saliva. Its action, however, is especially directed to the lungs; and its expectorant virtues are those for which it is chiefly employed. It was introduced into practice about a century ago by Dr. Tennant, of Virginia, who recommended it as a cure for the bite of the rattlesnake, and in various pectoral complaints. As an expectorant it is employed in cases not attended with acute inflammatory action, or in which the inflammation has been in great measure subdued. It is peculiarly useful in chronic catarrhal affections, the secondary stages of croup, and in peripneumonia notha after sufficient depletion. By Dr. Archer, of Maryland, it was recommended in the early stages of croup; but is now seldom given, unless in combination with squill and an antimonial, as in the *Syrupus Scillæ Compositus*. Employed so as to purge and vomit, it has proved useful in rheumatism; and some cases of dropsy are said to have been cured by it. It has also been recommended in amenorrhœa.

The dose of powdered seneka is from ten to twenty grains; but the medicine is more frequently administered in decoction. (See *Decoctum Senegæ*.) A syrup and alcoholic extract are officinal. The dose of the former is one or two fluidrachms, of the latter from one to three grains. A tincture is directed in the Br. Pharmacopœia. Polygalic acid may be employed in the dose of from the fourth of a grain to a grain, and may be administered either in pill or powder, or dissolved in hot water, with the addition, in any of its forms, of gum and sugar to obtund its acrimony. A formula for its preparation, by Professor Procter, has been published in the *Am. Journ. of Pharm.*, March, 1860, p. 150.

Cassia. See CASSIA FISTULA.

The plants which yield senna belong to the genus Cassia, of which several species contribute to furnish the drug. These were confounded together by Linnæus in a single species, which he named Cassia Senna. Since his time the subject has been more thoroughly investigated, especially by Delile, who accompanied the French expedition to Egypt, and had an opportunity of examining the plant in its native country. Botanists at present distinguish at least three species, C. acutifolia, C. obovata, and C. elongata, as the source of commercial senna; and it is probable that two others, *C. lanceolata* of Forskhal and *C. Æthiopica* of Guibourt, contribute towards it. The first three are recognised by the U. S. Pharmacopœia.

1. *Cassia acutifolia.* Delile, *Flore d'Égypte,* lxxv. tab. 27, f. 1.—*C. lanceolata.* De Candolle; Carson, *Illust. of Med. Bot.* i. 34, pl. 27. This is described as a small undershrub, two or three feet high, with a straight, woody, branching, whitish stem; but, according to Landerer, the senna plant attains the height of eight or ten feet in the African deserts. The leaves are alternate and pinnate, with glandless footstalks, and two small narrow pointed stipules at the base. The leaflets, of which from four to six pairs belong to each leaf, are almost sessile, oval-lanceolate, acute, oblique at their base, nerved, from half an inch to an inch long, and of a yellowish-green colour. The flowers are yellow, and in axillary spikes. The fruit is a flat, elliptical, obtuse, membranous, smooth, grayish-brown, bivalvular legume, about an inch long and half an inch broad, scarcely if at all curved, and divided into six or seven cells, each containing a hard, heart-shaped, ash-coloured seed. C. acutifolia grows wild in great abundance in Upper Egypt, Nubia, Sennaar, and other parts of Africa. This species furnishes the greater part of the variety known in commerce by the name of Alexandria senna.

2. *Cassia obovata.* Colladon, *Monographie des Casses;* De Cand. *Prodrom.* ii. 492; Carson, *Illust. of Med. Bot.* i. 35, pl. 28. The stem of this species is rather shorter than that of C. acutifolia, rising to the height of only a foot and a half. The leaves have from five to seven pairs of leaflets, which are obovate, very obtuse, sometimes mucronate, in other respects similar to those of the preceding species. The flowers are in axillary spikes, of which the peduncles are longer than the leaves of the plant. The legumes are very much compressed, curved almost into the kidney form, of a greenish-brown colour, and covered with a very short down, which is perceptible only by the aid of a magnifying glass. They contain from eight to ten seeds. The *C. obtusata* of Hayne, with obovate, truncated, emarginate leaflets, is probably a mere variety of this species. The plant, which according to Merat is annual, grows wild in Syria, Egypt, and Senegambia; and is said to have been cultivated successfully in Italy, Spain, and the West Indies. At present it grows wild so abundantly in some parts of Jamaica as to have suggested, to a resident of the island, the propriety of cultivating it for the English and American markets. (*Pharm. Journ. and Trans.,* Sept. 1867, p. 143.) It yields the variety of senna called in Europe Aleppo senna, and contributes to the Alexandrian.

3. *Cassia elongata.* Lemaire, *Journ. de Pharm.* vii. 345; Fée, *Journ. de Chim. Méd.* vi. 232; Carson, *Illust. of Med. Bot.* i. 36, pl. 29. This name was conferred by M. Lemaire upon the plant from which the India senna of com-

merce is derived. The botanical description was completed by M. Fée, from dried specimens of the leaves and fruit found by him in unassorted parcels of this variety of senna. Dr. Wallich afterwards succeeded in raising the plant from seeds found in a parcel of senna taken to Calcutta from Arabia; and it has been described by Dr. Royle, Wight & Arnott, and Dr. Lindley. As usually grown, it is annual; but with care it may be made to live through the year, and then assumes the character of an undershrub. It has an erect, smooth stem, and pinnate leaves, with from four to eight pairs of leaflets. These are nearly sessile, lanceolate, obscurely mucronate, oblique at the base, smooth above and somewhat downy beneath, with the veins turned inwards so as to form a wavy line immediately within the edge of the leaflet. The most striking character of the leaflet is its length, which varies from an inch to twenty lines. The petioles are without glands; the stipules minute, spreading, and semi-hastate. The flowers are bright-yellow, and arranged in axillary and terminal racemes, rather longer than the leaves. The legume is oblong, membranous, tapering abruptly at the base, rounded at the apex, and an inch and a half long by somewhat more than half an inch broad. This plant is a native of the southern parts of Arabia. It has been said also to grow in the interior of India, and is at present cultivated at Tinnevelly for medical use.

Besides the three officinal species above described, the *C. lanceolata* of Forskhal, found by that author growing in the deserts of Arabia, is admitted by Lindley and others as a distinct species. Some difference, however, of opinion exists upon this point. De Candolle considered it a variety of the C. acutifolia of Delile, from which it differs chiefly in having leaflets with glandular petioles; and, as Forskhal's description preceded that of Delile, he designated the species by the name of C. lanceolata. Forskhal's plant has been supposed by some to be the source of the India or Mocha senna; but the leaflets in this variety are much longer than those of C. lanceolata, from which the plant differs also in having no gland on the petiole. Niebuhr informs us that he found the Alexandria senna growing in the Arabian territory of *Abuarish*, whence it is taken by the Arabs to Mecca and Jedda. This is probably the C. lanceolata of Forskhal. It is highly probable that this species is the source of a variety of senna which has been brought to this market under the name of Mecca senna.*

Cassia Æthiopica of Guibourt (*C. ovata* of Merat), formerly confounded with C. acutifolia, is considered by Dr. Lindley as undoubtedly a distinct species. It grows in Nubia, Fezzan to the south of Tripoli, and probably, according to Guibourt, throughout Ethiopia. It is from this plant that the *Tripoli senna* of commerce is derived.

Commercial History. Several varieties of this valuable drug are known in commerce. Of these, four have been received in America, the Alexandria, the Tripoli, the India, and the Mecca senna.

1. *Alexandria Senna.* Though the name of this variety is derived from the Egyptian port at which it is shipped, it is in fact gathered very far in the interior. The Alexandria senna does not consist exclusively of the product of one species of Cassia. The history of its preparation is not destitute of interest. The senna plants of Upper Egypt yield two crops annually, one in spring and the other in autumn. They are gathered chiefly in the country beyond Sienne.

* The following are the botanical characters of this and the next-mentioned species.

1. *C. lanceolata.* Forskhal; Lindley, *Flor. Med.* p. 259. "Leaflets in four or five pairs, never more; oblong, and either acute or obtuse, not at all ovate or lanceolate, and perfectly free from downiness even when young; the petioles have constantly a small round brown gland, a little above the base. The pods are erect, oblong, tapering to the base, obtuse, turgid, mucronate, rather falcate, especially when young, at which time they are sparingly covered with coarse scattered hairs." (*Lindley.*)

2. *C. Æthiopica.* Guibourt, *Hist. Ab. des Drogues, &c.* ii. 219; Lindley, *Flor. Med.* p. 259. The plant is about eighteen inches high. The footstalks have a gland at the base, and another between each pair of leaflets. There are from three to five pairs of leaflets, which are pubescent, oval-lanceolate, from seven to nine lines in length, and three or four in breadth, rather shorter and less acute than those of C. acutifolia. The legume is flat, smooth, not reniform, rounded, about an inch long, with from three to five seeds.

The natives cut the plants, and, having dried them in the sun, strip off the leaves and pods, which they pack in bales, and send to Boulac, in the vicinity of Cairo, the great entrepot for this article of Egyptian commerce. This senna from Upper Egypt, consisting chiefly though not exclusively of the product of C. acutifolia, was here formerly mixed with the leaflets of C. obovata, brought from other parts of Egypt, and even from Syria, with the leaves of *Cynanchum oleæfolium* (*C. Argel* of Delile), known commonly by the name of *argel* or *arguel*, and sometimes with those of *Tephrosia Apollinea* of De Candolle, a leguminous plant growing in Egypt and Nubia. According to M. Royer, the proportions in which the three chief constituents of this mixture were added together, were five parts of C. acutifolia, three of C. obovata, and two of Cynanchum. Thus prepared, the senna was again packed in bales, and transmitted to Alexandria. But at present there is no such uniformity in the constitution of Alexandria senna; and, though the three chief ingredients may still sometimes be found in it, they are not in the same fixed proportions; and not unfrequently the Cynanchum leaves are wholly wanting. This variety of senna is often called in French pharmaceutic works *sênê de la palthe*, a name derived from an impost formerly laid upon it by the Ottoman Porte.

A parcel of Alexandria senna, as it was formerly brought to market, consisted of the following ingredients:—1. The leaflets of C. acutifolia, characterized by their acute form, and their length, almost always less than an inch; 2. the leaflets of C. obovata, known by their rounded very obtuse summit, which is sometimes furnished with a small projecting point, and by their gradual diminution in breadth towards their base; 3. the pods, broken leafstalks, flowers, and fine fragments of other parts of one or both of these species; 4. the leaves of Cynanchum oleæfolium, which are distinguishable by their length, almost always more than an inch, their greater thickness and firmness, the absence of any visible lateral nerves on their under surface, their somewhat lighter colour, and the regularity of their base. In this last character they strikingly differ from the genuine senna leaflets, which, from whatever species derived, are always marked by obliquity at their base, one side being inserted in the petiole at a point somewhat lower than the other, and at a different angle. Discrimination between this and the other ingredients is of some importance, as the Cynanchum must be considered an adulteration. It is said by the French writers to produce hypercatharsis and much irritation of the bowels; but was found by Christison and Mayer to occasion griping and protracted nausea, with little purgation. The flowers and fruit of the Cynanchum were also often present, the former white, and in small corymbs, the latter an ovoid follicle rather larger than an orange seed. Besides the above constituents of Alexandria senna, it occasionally contained leaflets of genuine senna, much longer than those of the acutifolia or obovata, equalling in this respect the Cynanchum, which they also somewhat resembled in form. They were distinguishable, however, by their greater thinness, the distinctness of their lateral nerves, and the irregularity of their base. The leaflets and fruit of *Tephrosia Apollinea*, which have been an occasional impurity in this variety of senna, may be distinguished, the former by their downy surface, their obovate-oblong, emarginate shape, their parallel unbranched lateral nerves, and by being usually folded longitudinally; the latter, by its dimensions, being from an inch to an inch and a half long, and only two lines broad. As now imported, Alexandria senna is often quite free from the leaves of Cynanchum, and may have few or none of the leaflets of obovate senna. It is probably brought directly to Alexandria from Upper Egypt, without having undergone intermixture at Boulac or other intervening place. In Europe, this senna is said to have been sometimes adulterated with the leaflets of *Collutea arborescens* or bladder senna, and the leaves of *Coriaria myrtifolia*, a plant of Southern Europe, said to be astringent and even poisonous. An account of the former of these plants is given in *Part* III. The leaflets of the Coriaria are ovate-lanceolate, grayish-green with a bluish tint, and are readily known, when not too much broken up, by their strongly marked midrib, and two lateral nerves running from the base

nearly to the summit. They are chemically distinguished by giving a whitish precipitate with solution of gelatin, and a bluish-black one with the salts of sesquioxide of iron, proving the presence of tannin. Their poisonous properties are denied by Peschier. According to Bouchardat, they are closely analogous to strychnia in their effects. Another addition to Alexandria senna has been detected by M. Lacroix, of Macon, in France, in the leaves of the *Globularia Turbith* (*Globularia alypum*, Linn.), which seem to have taken the place of the *Colutea arborescens*, because more closely resembling the senna leaflet. The leaves of the Globularia are spatulate, much enlarged towards the upper end, rounded at the extremity, but always terminating in a short sharp point. Besides, they are brown, thick, firm, and hard to the touch; while those of the Colutea are green, very thin, and soft. They have an acrid, very bitter taste, but are without nauseous odour. They are asserted to be cathartic, but milder than senna, and capable of being substituted for it in twice the dose. (*Journ. de Pharm.*, 4e sér., i. 413.) According to Prof. Bentley, the adulteration of Alexandria senna with argel, though for some time suspended, has of late years been resumed, and is now practised to a considerable extent, at least in relation to the drug as it reaches the English market. (*Pharm. Journ.*, April, 1861, p. 497.)

2. *Tripoli Senna.* Genuine Tripoli senna consists in general exclusively of the leaflets of one species of Cassia, formerly considered as a variety of *C. acutifolia*, but now admitted to be distinct, and named *C. Æthiopica*. The leaflets, however, are much broken up; and it is probably on this account that the variety is usually less esteemed than the Alexandrian. The aspect given to it by this state of comminution, and by the uniformity of its constitution, enables the eye at once to distinguish it from the other varieties of senna. The leaflets, moreover, are shorter, less acute, thinner, and more fragile than those of C. acutifolia in Alexandria senna; and their nerves are much less distinct. The general opinion at one time was, that it was brought from Sennaar and Nubia to Tripoli in caravans; but it is reasonably asked by M. Fée, how it could be afforded at a cheaper price than the Alexandrian, if thus brought on the backs of camels a distance of eight hundred leagues through the desert. It is probably collected in Fezzan, immediately south of Tripoli.

3. *India senna.* This variety is in Europe sometimes called *Mocha senna*, probably because obtained originally from that port. It derives its name of India senna from the route by which it reaches us. Though produced in Arabia, it is brought to this country and Europe from Calcutta, Bombay, and possibly other ports of Hindostan. It consists of the leaflets of Cassia elongata, with some of the leafstalks and pods intermixed. The eye is at once struck by the great length and comparative narrowness of the leaflets, so that the variety may be readily distinguished. The pike-like shape of the leaflet has given rise to the name of *sênè de la pique*, by which it is known in French pharmacy. Many of the leaflets have a yellowish, dark-brown, or blackish colour, probably from exposure after collection; and the variety has commonly in mass a characteristic dull tawny hue. It is generally considered inferior in purgative power. Leaflets of a senna resembling the Indian were brought by Dr. Livingstone from Southern Africa, where the plant grows abundantly. (Bentley, *Pharm. Journ.*, xvii. 499.)

A variety of India senna has reached this country, which is the produce of Hindostan, being cultivated at Tinnevelly, and probably other places in the south of the Peninsula. The plant was originally raised from seeds obtained from the Red Sea, and is the same as that from which the common India senna is derived. The drug is exported from Madras to England, where it is known by the name of *Tinnevelly senna*. It is a fine unmixed variety, consisting of unbroken leaflets, from one to two or more inches long, and sometimes half an inch in their greatest breadth, thin, flexible, and of a fine green colour. Mr. T. B. Groves, however, states as the result of his experiments, that Tinnevelly senna contains much less of the active principle than the Alexandrian; the latter yielding half as much again as the former. (*Pharm. Journ. and Trans*, Oct. 1868, p. 202.)

4. *Mecca senna.* After the publication of the fifth edition of this Dispensatory, a variety of senna was imported under the name of *Mecca senna*, consisting of the leaflets, pods, broken stems, and petioles of a single species of Cassia. The leaflets were oblong-lanceolate, on the average longer and narrower than those of C. acutifolia, and shorter than those of C. elongata. The variety in mass had a yellowish or tawny hue, more like that of India than that of Alexandria senna. May it not have been the product of the C. lanceolata of Forskhal? We might infer so from the name, and from the character of the leaflet. Landerer, however, speaks of a valuable variety of senna, characterized by the large size of the leaflets, and sold under the name of Mecca senna, which he says comes from the interior of Africa.

Commercial senna is prepared for use by picking out the leaflets, and rejecting the leafstalks, the small fragments, and the leaves of other plants. The pods are also rejected by some apothecaries; but they possess considerable cathartic power, though said to be milder than the leaves.

Properties. The odour of senna is faint and sickly; the taste slightly bitter, sweetish, and nauseous. Water and diluted alcohol extract its active principles. Pure alcohol extracts them but imperfectly. (Bley and Diesel, *Pharm. Central Blatt*, Feb. 1849, p. 126.) The leaves are said to yield about one-third of their weight to boiling water. The infusion is of a deep reddish-brown colour, and has the odour and taste of the leaves. When exposed to the air for a short time, it deposits a yellowish insoluble precipitate, supposed to result from the union of extractive matter with oxygen. The nature of this precipitate, however, is not well understood. Decoction also produces some change in the principles of senna, by which its medicinal virtues have been supposed to be impaired; but some experiments of B. Heerlein would seem to show that this opinion is incorrect. An extract prepared by boiling down an infusion, redissolving the residue, and again boiling down to a solid consistence, was found to operate actively in a dose equivalent to a drachm of the leaves. (*Pharm. Cent. Blatt*, 1851, p. 909.) To diluted alcohol it imparts the same reddish-brown colour as to water; but rectified alcohol and ether, digested upon the powdered leaves, become of a deep olive-green. The analysis of senna by MM. Lassaigne and Feneulle furnished the following results. The leaves contain — 1. a peculiar principle called cathartin; 2. chlorophyll, or the green colouring matter of leaves; 3. a fixed oil; 4. a small quantity of volatile oil; 5. albumen; 6. a yellow colouring matter; 7. mucilage; 8. salts of the vegetable acids, viz., malate and tartrate of lime and acetate of potassa; and 9. mineral salts. The pods are composed of the same principles, with the exception of chlorophyll, the place of which is supplied by a peculiar colouring matter. (*Journ. de Pharm.*, vii. 548, and ix. 58.) *Cathartin* was thought to be the active principle of senna; but upon trial it has proved to possess little power; and it is now believed to be a complex body, consisting, according to Bley and Diesel, of a mixture of resinous and extractive matter. It is an uncrystallizable substance, having a peculiar smell, a bitter, nauseous taste, and a reddish-yellow colour; is soluble in every proportion in water and alcohol, but insoluble in ether; and in its dry state attracts moisture from the air. It is prepared in the following manner. To a filtered decoction of senna the solution of acetate of lead is added; and the precipitate which forms is separated. A stream of hydrosulphuric acid is then made to pass through the liquor in order to precipitate the lead, and the sulphuret produced is removed by filtration. The liquid is now evaporated to the consistence of an extract; the product is treated with rectified alcohol; and the alcoholic solution is evaporated. To the extract thus obtained sulphuric acid diluted with alcohol is added, in order to decompose the acetate of potassa which it contains; the sulphate of potassa is separated by filtration; the excess of sulphuric acid by acetate of lead; the excess of acetate of lead by hydrosulphuric acid; and the sulphuret of lead by another filtration. The liquid being now evaporated yields cathartin. This substance must not be confounded with a purgative principle, also called cathartin, which exists in Rhamnus catharticus. Bley and Diesel found in senna a peculiar

yellow resin which they named *chrysoretin*, a brown resin and brown extractive which they could not fully separate, pectin, gummy extractive, chlorophyll, fatty matter, and various salts. (*Pharm. Cent. Blatt*, Feb. 1849, p. 126.) M. Batka, besides the components enumerated by MM. Lassaigne and Feneulle, found chrysophanic acid, previously discovered by Martius, legumin (instead of albumen), gum, sugar, *sennacrin* (instead of cathartin, without bitterness), *sennaretin*, magnesia and soda, and the sennatannic, oxalic, carbonic, silicic, phosphoric, sulphuric, and muriatic acids. (*Journ. de Pharm.*, 4e sér., i. 136.)

At length there is good reason to believe that the real active principle of senna has been isolated. The substance obtained by Mr. Robert Rau, of Bethlehem, Pa., and believed by him to be the purgative ingredient, has not withstood the test of subsequent investigation. (*Am. Journ. of Pharm.*, May, 1866, p. 193.) Mr. Thos. B. Groves, of London, was on the point of isolating the principle, when its existence was announced by Dragendorf and Kubly, to whom the credit of the discovery belongs, and who have named it *cathartic acid.* It appears to be a glucoside, and has an extraordinarily complex composition, containing sulphur as well as nitrogen; and its formula is stated as $C_{180}H_{36}N_2SO_{82}$. This accounts for its great facility of decomposition, and the great difficulty of its discovery. It is insoluble in water, strong alcohol, and ether, but its saline compounds with the alkalies and earth are readily dissolved. Its ammonia salt is precipitated by the salts of silver, tin, mercury, copper, and lead; but tannin, the antimonial salts, and the yellow and red prussiates have no effect on it. Alkalies with heat decompose it; and, boiled with a mineral acid, it separates into a variety of glucose and a peculiar acid called the *cathartogenic.* It is prepared by partially precipitating with alcohol a watery infusion of senna, concentrating to a syrupy consistence *in vacuo*, filtering, treating the filtrate with a large proportion of absolute alcohol, and repeatedly dissolving in water and precipitating by alcohol the precipitate thus obtained. It is purified by submitting it, dissolved in moderately strong muriatic acid, to dialysis on a diaphragm of parchment paper; cathartic acid having strong collodial properties. Mr. Groves found that cathartate of ammonia purged moderately in the dose of $3\frac{3}{4}$ grains, with considerable griping; and that of certain mixed cathartates $7\frac{1}{2}$ grains purged violently with much griping and sickness, and continued to act through most of a day. He considers 4 grains as a fair dose. It should be given in connection with an aromatic and a saline cathartic. The cathartate of magnesia is soluble. The salts of this acid in watery solution are decomposed and rendered inert by long exposure to heat in contact with the air. (Groves, *Pharm. Journ. and Trans.*, Oct. 1868, pp. 200–1.) The same chemists found chrysophanic acid in small proportions, two substances called respectively *sennacrol* and *sennapicrin*, and a peculiar non-fermentable saccharine principle, with the formula $C_{42}H_{44}O_{38}$, which they have named *catharto-mannite.* (*Journ. de Pharm.*, 4e sér., v. 475.)

Incompatibles. Many substances produce precipitates with the infusion of senna; but it does not follow that they are all medicinally incompatible; as they may remove ingredients which have no therapeutical effect, and leave the active principles untouched. Cathartin is precipitated by infusion of galls and solution of subacetate of lead. Acetate of lead and tartarized antimony, which disturb the infusion, have no effect upon the solution of this substance.

Medical Properties and Uses. Senna was first used as a medicine by the Arabians. It was noticed in their writings so early as the ninth century; and the name itself is Arabic. It is a prompt, efficient, and very safe purgative, well calculated for fevers and febrile complaints, and other cases in which a decided but not violent impression is desired. A disadvantage is that it is apt to produce severe griping. This effect, however, may be obviated by combining with the senna some aromatic, and some one of the alkaline salts, especially bitartrate of potassa, tartrate of potassa, or sulphate of magnesia. The explanation which attributes the griping property to the oxidized extractive, and its prevention by the saline substances to their influence in promoting the solubility of that

principle, is not satisfactory. The purgative effect of senna is considerably increased by combination with bitters; a fact noticed by Cullen, and abundantly confirmed by subsequent experience. The decoction of guaiac is said to exert a similar influence. Senna yields one or more of its principles to the urine; as, from twenty to thirty minutes after it has been taken, this secretion acquires the property of being reddened by ammonia. (*Journ. de Pharm.*, Août, 1863, p 161.) The dose of senna in powder is from half a drachm to two drachms; but its bulk renders it of inconvenient administration; and it is not often prescribed in this state. Besides, the powder is said to undergo decomposition, and to become mouldy on exposure to a damp air. The form of infusion is almost universally preferred. (See *Infusum Sennæ.*) The medicine is also used in the forms of confection, fluid extract, syrup, and tincture, all of which are officinal.

Senna taken by nurses is said to purge sucking infants, and an infusion injected into the veins operates as a cathartic.

SERPENTARIA. *U.S.*

Serpentaria. Virginia Snakeroot.

The root of Aristolochia Serpentaria, of Aristolochia reticulata, and of other species of Aristolochia. *U. S.*

Off. Syn. SERPENTARIÆ RADIX. *Serpentary Root.* The dried rhizome of Aristolochia Serpentaria. *Br.*

Serpentaire de Virginie, *Fr.;* Virginianische Schlangenwurzel, *Germ.;* Serpentaria Virginiana, *Ital., Span.*

ARISTOLOCHIA. *Sex. Syst.* Gynandria Hexandria.—*Nat Ord.* Aristolochiaceæ.

Gen. Ch. Calyx none. *Corolla* one-petaled, ligulate, ventricose at the base. *Capsules* six-celled, many-seeded, inferior. *Willd.*

Many species of Aristolochia have been employed in medicine. The roots of all of the mare tonic and stimulant; and their supposed possession of emmenagogue properties has given origin to the name of the genus. *A. Clematitis*, *A. longa*, *A. rotunda*, and *A. Pistolochia* are still retained in many officinal catalogues of the continent of Europe, where they are indigenous. The root of *A. Clematitis* is very long, cylindrical, as thick as a goosequill or thicker, variously contorted, beset with the remains of the stems and radicles, of a grayish-brown colour, a strong peculiar odour, and an acrid bitter taste; that of *A. longa* is spindle-shaped, from a few inches to a foot in length, of the thickness of the thumb or thicker, fleshy, very brittle, grayish externally, brownish-yellow within, bitter, and of a strong disagreeable odour when fresh; that of *A. rotunda* is tuberous, roundish, heavy, fleshy, brownish on the exterior, grayish-yellow internally, and similar to the preceding in odour and taste; that of *A. Pistolochia* consists of numerous slender yellowish or brownish fibres, attached to a common head, and possessed of an agreeable aromatic odour, with a taste bitter and somewhat acrid. Many species of Aristolochia growing in the West Indies, Mexico, and South America, have attracted attention for their medicinal properties; and some, like our own snakeroot, have acquired the reputation of antidotes for the bites of serpents. In the East Indies, *A. Indica* is employed for similar purposes with the European and American species; and the Arabians are said by Forskhal to use the leaves of *A. sempervirens* as a counter-poison. We have in the United States six species, of which four—*A. Serpentaria*, *A. hirsuta*, *A. hastata*, and *A. reticulata*—contribute to furnish the snakeroot of the shops.

Aristolochia Serpentaria. Willd. *Sp. Plant.* iv 159; Bigelow, *Am. Med. Bot.* iii. 82; Barton, *Med. Bot.* ii. 41. This species of Aristolochia is an herbaceous plant, with a perennial root, which consists of numerous slender fibres proceeding from a short horizontal caudex. Several stems often rise from the same root. They are about eight or ten inches in height, slender, round, flexuose, jointed at

irregular distances, and frequently reddish or purple at the base. The leaves are oblong-cordate, acuminate, entire, of a pale yellowish-green colour, and supported on short petioles at the joints of the stem. The flowers proceed from the joints near the root, and stand singly on long, slender, round, jointed peduncles, which are sometimes furnished with one or two small scales, and bend downwards so as nearly to bury the flower in the earth or decayed leaves. There is no calyx. The corolla is purple, monopetalous, tubular, swelling at the base, contracted and curved in the middle, and terminating in a labiate border with lanceolate lips. The anthers—six or twelve in number—are sessile, attached to the under part of the stigma, which is roundish, divided into six parts, and supported by a short fleshy style upon an oblong, angular, hairy, inferior germ. The fruit is a hexangular, six-celled capsule, containing several small flat seeds.

The plant grows in rich shady woods, throughout the Middle, Southern, and Western States, abounding in the valley of the Ohio, and in the mountainous regions of our interior. It flowers in May and June. The root is collected in Western Pennsylvania and Virginia, in Ohio, Indiana, and Kentucky, and is brought eastward chiefly by the routes of Wheeling and Pittsburg. As it reaches Philadelphia, it is usually in bales containing about one hundred pounds, and is often mixed with the leaves and stems of the plant, and with dirt from which it has not been properly cleansed at the time of collection.

A. hirsuta. Muhlenberg, *Catalogue*, p. 81; Bridges, *Am. Journ. of Pharm.*, xiv. 121. In Muhlenberg's Catalogue this species was named without being described; and botanists, supposing from the name that it was identical with *A. tomentosa*, generally confounded the two plants But they are entirely distinct. A description of *A. hirsuta* in the handwriting of Muhlenberg, and a labelled specimen of the plant, in the possession of the Academy of Natural Sciences of this city, have been found to correspond with a dried specimen received by the author from Virginia. *A. tomentosa* is a climbing plant, growing in Louisiana on the banks of the Mississippi, and ascending to the summit of the highest trees. A plant in the garden of the author has a thick, creeping root, entirely different in shape from that of the officinal species, though possessed of an analogous odour. *A. hirsuta* has a root like that of *A. Serpentaria*, consisting of a knotty caudex, sending out numerous slender simple fibres, sometimes six inches in length. From this arise several jointed, flexuose, pubescent stems, less than a foot high, with one or two pubescent bractes, and several large roundish-cordate leaves, of which the lower are obtuse, the upper abruptly acuminate, and all pubescent on both sides and at the margin. From the joints near the root originate from one to three solitary peduncles, each bearing three or four leafy bractes and one flower. The peduncles, bractes, and corolla are all hairy. This species grows in Virginia, and perhaps other parts of the Western and Southern States. It probably contributes to afford the serpentaria of commerce; as its leaves have been found in bales of the drug.

A. hastata. Nuttall, *Gen. of N. Am. Plants*, p. 200.—*A. sagittata.* Mubl. *Catal.* This species, if indeed it can be considered a distinct species, differs from A. Serpentaria in having hastate, acute, somewhat cordate leaves, and the lip of the corolla ovate. It flourishes on the banks of the Mississippi, in the Carolinas, and elsewhere. Its root scarcely differs from that of the officinal plant, and is frequently mixed with it, as proved by the presence of the characteristic leaves of *A. hastata* in the parcels brought into market.

A. reticulata. Nuttall; Bridges, *Am. Journ. of Pharm.*, xvi. 118; Carson, *Illust. of Med. Bot.* ii. 32, pl. 77. This plant was probably first observed by Mr. Nuttall; as a specimen labelled "*A. reticulata*, Red river," in the handwriting of that botanist, is contained in the Herbarium of the Academy of Natural Sciences of Philadelphia. From this specimen, as well as from others found in parcels of the drug brought into market, a description was drawn up by Dr. Robert Bridges, and published in the *Am. Journ. of Pharmacy.* From a root, similar to that of *A. Serpentaria*, numerous short, slender, round, flexuose, jointed stems arise, usually simple, but sometimes branched near the root. The older

stems are slightly villous, the young densely pubescent. The leaves, which stand on very short villous petioles, are round or oblong-cordate, obtuse, reticulate, very prominently veined, and villous on both sides, especially upon the veins. From the lower joints of the stem four or five hairy, jointed peduncles proceed, which bear small leafy villous bractes at the joints, and several flowers on short pedicels. The flowers are small, purplish, and densely pubescent, especially at the base and on the germ. The hexangular capsule is deeply sulcate. This species grows in Louisiana, Texas, Arkansas, and the Indian Territory west of that State.

Bales of a new variety of serpentaria were some years since brought to Philadelphia, which is certainly the product of this species; as specimens of all parts of the plant have been found in the bales, and the roots, which differ somewhat from those before known, are homogeneous in character. One of these bales was brought from New Orleans, and was said to have come down the Red river, and to have been collected by the Indians. The chief difference between this and ordinary Virginia snakeroot is in the size of the radicles, which are much thicker and less interlaced in the new variety. Each root has usually a considerable portion of one or more stems attached to the caudex. The colour is yellowish. The odour and taste are scarcely if at all distinguishable from those of common serpentaria; and there is no doubt that the root is equally effectual as a medicine. From a chemical examination by Mr. Thomas S. Wiegand, it appears to have the same constituents, and to differ only in containing a somewhat larger proportion of gum, extractive, and volatile oil.

Properties. Virginia snakeroot, as found in the shops, is in tufts of long, slender, frequently interlaced, and brittle fibres, attached to a short, contorted, knotty head or caudex. The colour, which in the recent root is yellowish, becomes brown by time. That of the powder is grayish. The smell is strong, aromatic, and camphorous; the taste warm, very bitter, and also camphorous. The root yields all its virtues to water and alcohol, producing with the former a yellowish-brown infusion, with the latter a bright-greenish tincture, rendered turbid by the addition of water. Chevallier found in the root volatile oil, a yellow bitter principle soluble in water and alcohol, resin, gum, starch, albumen, lignin, and various salts. Bucholz obtained from 1000 parts, 5 of a green, fragrant volatile oil, 28·5 of a yellowish-green resin, 17 of extractive matter, 181 of gummy extract, 624 of lignin, and 144·5 of water. The active ingredients are probably the volatile oil, and the yellow bitter principle of Chevallier, which that chemist considers analogous to the bitter principle of quassia. The volatile oil passes over with water in distillation, rendering the liquid milky, and impregnating it with the odour of the root. Dr. Bigelow states that the liquid, on standing, deposits small crystals of camphor.

The roots of *Spigelia Marilandica* are sometimes found associated with serpentaria. They may be distinguished by the absence of the bitter taste, and, when the stem and foliage are attached, by the peculiar character of these parts of the plant. (See *Spigelia.*) We have occasionally seen the young roots of *Polygala Senega* mixed with serpentaria. Independently of their difference in odour and taste, they may be readily distinguished by being simple, and by a projecting line running from one end to the other of the root.

Medical Properties and Uses. Serpentaria is a stimulant tonic, acting also as a diaphoretic or diuretic, according to the mode of its application. Too largely taken, it occasions nausea, griping pains in the bowels, sometimes vomiting and dysenteric tenesmus. It is adapted to the treatment of typhoid fevers, whether idiopathic or symptomatic, when the system begins to feel the necessity for support, but is unable to bear active stimulation. In exanthematous diseases in which the eruption is tardy or has receded, and the grade of action is low, it is thought to be useful by promoting the cutaneous affection. It has also been highly recommended in intermitttent fevers; and, though itself generally inadequate to the cure of the complaint, often proves serviceable as an adjunct to Peruvian bark or sulphate of quinia. With the same remedies it is frequently

associated in the treatment of typhous diseases. It is sometimes given in dyspepsia, and is employed as a gargle in malignant sorethroat.

The dose of the powdered root is from ten to thirty grains; but the infusion is almost always preferred. (See *Infusum Serpentariæ.*) The decoction or extract would be an improper form; as the volatile oil, upon which the virtues of the medicine partly depend, is dissipated by boiling. There is, however, an officinal fluid extract, which is an efficient preparation.

Sesamum orientale. Willd. *Sp. Plant.* iii. 358; Rheed. *Hort. Malab.* ix. 54. "Leaves ovate-oblong, entire."

Sesamum Indicum. Willd. *Sp. Plant.* iii. 359; Curtis, *Bot. Mag.* vol. xli. t. 1688. "Leaves ovate-lanceolate, the inferior three-lobed, the superior undivided. Stem erect." There is reason to believe that this species is the one chiefly cultivated in our Southern States. At least we have found plants, raised in Philadelphia from seeds obtained from Georgia, to have its specific character, as given by Willdenow.

The benne plant of our Southern States is annual, with a branching stem four or five feet high, and bearing opposite, petiolate leaves, varying considerably in their shape. Those on the upper part of the plant are ovate-lanceolate, irregularly serrate, and pointed; those near the base three-lobed and sometimes ternate; and lobed leaves are not uncommon at all distances from the ground. The flowers are reddish-white, and stand solitarily upon short peduncles in the axils of the leaves. The fruit is an oblong capsule, with small, oval, yellowish seeds.

These two species of Sesamum are natives of the East Indies, and have been cultivated from time immemorial in various parts of Asia and Africa. From the latter continent it is supposed that seeds were brought by the negroes to the United States, where, as well as in the West Indies, one or both species are now cultivated to a considerable extent. The plant above described will grow vigorously in the gardens so far north as Philadelphia, though it does not usually ripen its seeds in this vicinity.

The seeds are employed as food by the negroes, who parch them over the fire, boil them in broths, make them into puddings, and prepare them in various other modes. By expression they yield a fixed oil, which, as well as the leaves, has been introduced into the secondary catalogue of the U. S. Pharmacopœia. M. Berjot obtained 53 per cent. of the oil by means of bisulphide of carbon.

1. *Benne Leaves.* These abound in a gummy matter, which they readily impart to water, forming a rich, bland mucilage, much used in the Southern States as a drink in various complaints to which demulcents are applicable; as in cholera infantum, diarrhœa, dysentery, catarrh, and affections of the urinary passages. The remedy has attracted attention also in the North, and has been

employed with favourable results in Philadelphia. One or two fresh leaves of full size, stirred about in half a pint of cool water, will soon render it sufficiently viscid. If dried, they should be introduced into hot water. The leaves also serve for the preparation of emollient cataplasms.

2. *Benne Oil.* This is inodorous, of a bland, sweetish taste, and will keep long without becoming rancid. It bears some resemblance to olive oil in its properties, and may be used for similar purposes. It is not a drying oil. At 55° F., it has the sp. gr. 0·919; and its point of congelation is 23° F. It is temporarily rendered green by a mixture of sulphuric and nitric acids; a property by which it may be detected when used to adulterate olive or almond oil. (Fluckiger, *Journ. de Pharm.*, 4e sér., v. 157; from *Schweitzer Wochenschrift für Pharm.*, 1866, no. 37.) It was known to the ancient Persians and Egyptians, and is highly esteemed by the modern Arabs and other people of the East, both as food, and as an external application to promote softness of the skin. Like olive oil, it is laxative in large doses. W.

SEVUM. *U. S.*

Suet.

The prepared suet of Ovis Aries. *U. S.*

Off. Syn. SEVUM PRÆPARATUM. *Prepared Suet.* The internal Fat of the abdomen of the sheep, Ovis Aries, purified by melting and straining. *Br.*

Suif, Graisse de mouton, *Fr.;* Hammelstalg, *Germ.;* Grasse duro, *Ital.;* Sebo, *Span.*

Suet is the fat of the sheep, taken chiefly from about the kidneys. It is prepared by cutting the fat into pieces, melting it with a moderate heat, and straining it through linen or flannel. In order to avoid too great a heat, the crude suet is sometimes purified by boiling it in a little water.

Mutton suet is of a firmer consistence, and requires a higher temperature for its fusion than any other animal fat. It is very white, sometimes brittle, inodorous, of a bland taste, insoluble in water, and nearly so in alcohol. Boiling alcohol, however, dissolves it, and deposits it upon cooling. It consists, according to Chevreul, of stearin, olein, and a small proportion of hircin. The two first-mentioned principles are described under the *Fixed Oils* (pages 581, 582). *Hircin* is a liquid like olein, from which it differs in being much more soluble in alcohol, and in yielding *hircic acid* by saponification.

Suet acquires by time an unpleasant smell, and becomes unfit for pharmaceutic purposes. It is employed to give a proper consistence to ointments, cerates, and plasters, and sometimes as a dressing to blisters.

QUASSIA. See QUASSIA.

Quassia Simaruba. Willd. *Sp. Plant.* ii. 568; Woodv. *Med. Bot.* p. 569, t. 203. — *Simaruba officinalis.* De Cand. *Prodrom.* i. 733. — *S. amara,* Aublet; Lindley, *Flor. Med.* p. 207. As this plant is unisexual, it belongs to the genus Simaruba of De Candolle and Lindley, those only being placed by these botanists in the genus Quassia which are hermaphrodite. But, as the Linnæan arrangement was adhered to in the case of Quassia excelsa, we continue to adhere to it in relation to this plant. (See *Quassia.*) It is a tree of considerable height and thickness, having alternate branches, with a bark which in the old tree is black and somewhat furrowed, in the young is smooth, gray, and marked

here and there with broad yellow spots. The leaves are alternate and abruptly pinnate, with a naked petiole, to which the leaflets are alternately attached by short footstalks. The leaflets are nearly elliptical, on the upper surface smooth and deep-green, on the under whitish. The flowers are yellow, and in long axillary panicles. In some descriptions they are stated to be monœcious, in others diœcious. According to Dr. Wright, the female flowers are never found in Jamaica on the same tree with the male. The number of stamens is ten.

The tree is found in the West Indies and Guyana. In Jamaica it is called the *mountain damson*. *Simaruba amara* of Aublet, which grows in Guyana, and has generally been considered identical with *Q. Simaruba*, is believed by Hayne to be a distinct species; the Jamaica plant having diœcious, while this has monœcious flowers. The bark of the root is the part employed; the wood itself being nearly tasteless and inert.

Simaruba bark is in long pieces, some inches in breadth, folded lengthwise, light, flexible, tenacious, very fibrous, externally of a light brownish-yellow colour, rough, warty, and marked with transverse ridges, internally of a pale-yellow. It is without smell, and of a bitter taste. It readily imparts its virtues, at ordinary temperatures, to water and alcohol. The infusion is at least equally bitter with the decoction, which becomes turbid as it cools. Its constituents, according to M. Morin, are a bitter principle identical with *quassin*, a resinous matter, a volatile oil having the odour of benzoin, malic acid, gallic acid in very minute proportion, an ammoniacal salt, malate and oxalate of lime, some mineral salts, oxide of iron, silica, ulmin, and lignin.

Medical Properties and Uses. Simaruba possesses the same tonic properties as other simple bitters, and may be employed for the same purposes. In large doses it is said to purge and vomit. It was introduced into France in 1713 from Guyana, where it had previously been used as a remedy for dysentery. In the treatment of this disease and of obstinate diarrhœa, it afterwards obtained much credit in Europe; but Cullen was right in denying to it any specific control over these complaints. It operates simply as a tonic; and, though occasionally beneficial in relaxed and debilitated states of the alimentary canal, would do much harm if indiscriminately prescribed in dysenteric cases. On account of its difficult pulverization, it is seldom given in substance. The best mode of administration is by infusion. The dose is from a scruple to a drachm.

Sinapis nigra. Willd. *Sp. Plant.* iii. 555; Woodv. *Med. Bot.* p. 403, t. 146. Common or black mustard is an annual plant, with a stem three or four feet in height, divided and subdivided into numerous spreading branches. The leaves are petiolate and variously shaped. Those near the root are large, rough, lyrate-pinnate, and unequally toothed; those higher on the stem are smooth and less lobed; and the uppermost are entire, narrow, smooth, and dependent. The flowers are small, yellow, with a coloured calyx, and stand closely together upon peduncles at the upper part of the branches. The pods are smooth, erect, nearly parallel with the branches, quadrangular, furnished with a short beak, and occupied by numerous seeds.

Sinapis alba. Willd. *Sp. Plant.* iii. 555; Smith, *Flor. Brit.* 721. The white mustard is also annual. It is rather smaller than the preceding species. The lower leaves are deeply pinnatifid, the upper sublyrate, and all irregularly toothed, rugged, with stiff hairs on both sides and pale-green. The flowers are in racemes, with yellow petals, and linear, green calycine leaflets. The pods are spreading, bristly, rugged, roundish, swelling in the position of the seeds, ribbed, and provided with a very long ensiform beak.

Both plants are natives of Europe and cultivated in our gardens; and *S. nigra* has become naturalized in some parts of this country. Their flowers appear in June. The seeds are kept in the shops, both whole and in the state of very fine powder, as prepared by the manufacturers for the table.

Black mustard seeds are small, globular, of a deep-brown colour, slightly rugose on the surface, and internally yellow. In the entire state they are inodorous, but have a distinct smell in powder, and, when rubbed with water or vinegar, exhale a strong pungent odour, sufficient in some instances to excite a flow of tears. Their taste is bitterish, hot, and pungent, but not permanent. *White mustard seeds* are much larger, of a yellowish colour, and less pungent taste. Both afford a yellow powder, which has a somewhat unctuous appearance, and cakes when compressed. This is commonly called *flour of mustard*, or simply *mustard*, and is prepared by crushing and pounding the seeds, and then sifting them; the purest flour being obtained by a second sifting. Both the black and the white seeds are used in its preparation. It is often adulterated with wheat flour coloured by turmeric, to which red pepper is added to render the mixture sufficiently hot. The skin of white mustard seeds contains a mucilaginous substance, which is extracted by boiling water. When bruised or powdered, both kinds impart their active properties wholly to water, but in a very slight degree to alcohol. They yield upon pressure a fixed oil, called *oil of mustard*, of a greenish-yellow colour, little smell, and a mild not unpleasant taste; and the portion which remains is even more pungent than the unpressed seeds. The fixed oil of mustard yields, upon saponification, a peculiar acid, for which the name of *erucic acid* has been proposed. (*Chem. Gaz.*, vii. 163.)

It has been long known that black mustard seeds yield by distillation with water a very pungent volatile oil, containing sulphur. Guibourt conjectured, and Robiquet and Boutron proved, that this oil does not pre-exist in the seeds, but is produced by the action of water. Hence the absence or very slight degree of odour in the seeds when bruised in a dry state, and their pungency when water is added. It seemed reasonable to suppose that the reaction in this case was similar to that exercised by water upon bitter almonds (see *Amygdala Amara*); and this has been proved to be the fact by the experiments of Simon, Bussy, Boutron, and Frémy. According to M. Bussy, there are two peculiar principles in black mustard seeds, one named by him *myronic acid*, existing in the seeds in the state of *myronate of potassa;* the other *myrosyne*, closely analogous in character to the albuminous constituent of almonds called *emulsin.* When water is added to black mustard seed, the myrosyne, acting the part of a ferment, determines a reaction between the water and myronate of potassa, which results in the production of the volatile oil. The same thing happens when any one of the myronates is brought into contact with water and myrosyne. The presence of the last-mentioned principle is essential. Like emulsin, it

becomes inoperative when coagulated by heat, alcohol, or the acids; and, if black mustard seeds be subjected to either of these agencies previously to the addition of water, they will yield no volatile oil. The myrosyne, however, sometimes partially recovers its power by continued contact with water. This substance is found also in white mustard seeds, but without myronate of potassa. If, therefore, white mustard seeds be added to the black in which the myrosyne has been coagulated, the volatile oil will be generated on the application of water. Though closely analogous to emulsin, myrosyne is yet distinct, as its place cannot be supplied by emulsin with the same effect. (*Journ. de Pharm.*, xxvi. 39.) Simon obtained results somewhat different from those of M. Bussy. The former chemist succeeded in procuring a peculiar crystalline principle from the seeds which he called *sinapisin*, and which, upon contact with water and the albuminous principle of the seeds, emitted the odour of the oil of mustard. Dr. S. von Thielau asserts that, though the volatile oil is produced by the reaction between myrosyne and some principle existing in black mustard, yet this principle is not myronate of potassa, the existence of the so-called myronic acid being fabulous. (See *Am. Journ. of Pharm.*, Nov. 1858, p. 540.) MM. Ludgwig and Lange, however, have found myronic acid in abundance in black mustard seeds. They have also found along with it another substance, apparently the acid salt of a nitrogeno-sulphur alkaloid, which likewise yields the volatile oil of mustard with myrosyne. (*Journ. de Pharm.*, Mars, 1861, p. 236.)

Oleum Sinapis. The *volatile oil of mustard* is usually obtained from seeds which have been deprived of their fixed oil by pressure. It is a colourless or pale-yellow liquid, rather heavier than water, of an exceedingly pungent odour, of an acrid burning taste, and of the sp. gr. 1·015. It boils at about 298°; is slightly soluble in water, and readily so in alcohol and ether; with alkaline solutions yields sulphocyanides; and consists, according to M. Löwig and Dr. Will, of nitrogen, carbon, hydrogen, and sulphur; its formula being $NC_8H_5S_2$. Dr. Will considers it a sulphocyanide of *allyl* (C_6H_5), the compound radical of oil of garlic, which is considered a sulphuret of allyl.* (*Chem. Gaz.*, nos. 62 and 64.) It is the principle upon which black mustard seeds depend for their activity. According to Zeller, the seeds yield from 0·33 to 0·63 per cent. of the oil. As it is often adulterated with other oils, a test has been proposed consisting of concentrated sulphuric acid, 50 drops of which are to be mixed with 5 drops of the suspected oil in a small glass tube. If the oil is pure, little change of colour is produced; but if any adulterating oil be present, a red or brown colour will soon appear. Rectified oil of petroleum is the only exception, as the colour of this is not affected by the acid; but it would be recognised by its insolubility in sulphuric acid. (See *Am. Journ. of Pharm.*, July, 1865, p. 285.) Adulteration with alcohol is readily detected by its much lower boiling point, which also enables it to be separated by distillation. The volatile oil of mustard has recently been employed as a substitute for the mustard plaster. For this purpose one part may be mixed with sixty parts of alcohol, and the mixture applied sprinkled not too thickly on piline. It acts speedily and efficiently. (*Pharm. Journ. and Trans.*, July, 1865, p. 34.)

White mustard seeds do not yield volatile oil when treated with water; but an acrid fixed principle is developed, which renders these seeds applicable to the same purposes as the other variety. MM. Robiquet and Boutron, who ascertained this fact, concluded that the acrid principle resulted from the reaction of water upon *sulpho-sinapisin*, discovered in the seeds by MM. Henry, jun., and Garot. Their reason for this belief was that mustard, which had been deprived of this ingredient, was incapable of developing the acrid principle. The myro-

* Volatile oil of mustard has been produced artificially, by MM. Berthelot and S. de Luca, by treating iodide of propionyl (identical with allyl) (C_6H_5I) with sulphocyanuret of potassium. The iodine unites with potassium, and the liberated radical (C_6H_5) combines with the sulphocyanogen (NC_2S_2) to form volatile oil of mustard ($NC_8H_5S_2$). Iodide of propionyl is procured by treating glycerin with iodide of phosphorus, and differs from volatile oil of garlic (sulphuret of allyl), only in containing iodine instead of sulphur. (*Journ. de Pharm.*, Août, 1855, p. 124.)

syne is equally essential to the change here, as to that which occurs in black mustard; and the reaction equally fails, if this principle be previously rendered inert by heat, alcohol, or the acids. MM. Boutron and Frémy state that not only the acrid principle of white mustard, but hydrosulphocyanic acid also results from the reaction above explained; and this observation renders still closer the analogy between the changes that take place, upon contact with water, in mustard seeds and bitter almonds. (*Journ. de Pharm.*, xxvi. 50.)*

* As some may desire to push these investigations further, we give the properties of these peculiar principles, and the modes of procuring them.

Myronic acid is a fixed inodorous substance, of a bitter and sour taste, and acid reaction. When obtained separate from its bases, it forms a colourless solution; which by evaporation becomes of a thick consistence like molasses, without crystallizing. It is soluble in water and alcohol, but not in ether; and forms soluble salts with the alkalies, baryta, lime, and the oxides of lead and silver, all of which yield volatile oil of mustard, when mixed with an aqueous solution of myrosyne. It contains sulphur, besides nitrogen, carbon, hydrogen, and oxygen. It is obtained from the myronate of potassa by adding to 100 parts of that salt 38 parts of crystallized tartaric acid, concentrating the solution by evaporation, and then adding weak alcohol, which precipitates the bitartrate of potassa, and retains the myronic acid in solution. To obtain *myronate of potassa* from black mustard seeds, the powder, having been dried at 212°, and deprived of its fixed oil by pressure, is treated with strong alcohol in a displacement apparatus, and, when thus nearly exhausted of everything soluble in that liquid, is pressed and treated with water. The aqueous solution is evaporated, and, before it is too much concentrated, weak alcohol is added, which precipitates a glutinous matter. The solution being then carefully evaporated, deposits crystals of myronate of potassa, which may be obtained very pure and white by washing the mass with diluted alcohol. This salt is easily crystallizable in fine, large, transparent crystals, is unalterable in the air, very soluble in water, insoluble in pure alcohol, and of a bitter taste. MM. Ludgwig and Lange, who procured the myronate of potassa, by a process essentially the same as that of M. Bussy, in the quantity of 1 part from 500 parts of black mustard, give its composition as represented by the formula $KO,NC_{20}H_{19}S_4O_{18}$. (*Journ. de Pharm.*, Juin, 1861, p. 432.)

Myrosyne, when dry, has the character of an albuminous substance. It is soluble in water, forming a viscid solution which froths when agitated, and is coagulated by heat, alcohol, and the acids. It is obtained by treating white mustard seed with cold water, filtering the solution, evaporating it by a heat not exceeding 100°, and, when it is of the consistence of syrup, carefully adding alcohol, which causes a precipitate easily separable by decantation. If this be dissolved in water, and the solution evaporated as before, myrosyne is obtained, though not entirely pure. (*Journ. de Pharm.*, xxvi. 39.)

The *sinapisin* of Simon is in brilliant, white scaly crystals, sublimable by heat, soluble in alcohol, ether, and the fixed and volatile oils, but insoluble in acids and alkalies. To obtain it he exhausted black mustard seed with strong alcohol, distilled off the greater part of the alcohol, treated the residue several times with four or five times its weight of ether, from the ethereal solutions distilled off all the ether, treated the extract again with a smaller quantity of ether so as to leave behind insoluble substances, and repeated this process until the extract formed a perfectly clear solution without residue. The extract was then dissolved in cold strong alcohol, and the solution, having been decolorized with animal charcoal, was allowed to evaporate in the air. Simon obtained from 55 pounds of the seeds only 80 grains of crystallized sinapisin. (*Annal. der Pharm.*, xxvi. 291.)

Sulpho-sinapisin, the peculiar ingredient of white mustard seed, is white, crystallizable, inodorous, bitter, and soluble in alcohol and water, forming a yellow solution. It was at first thought by MM. Henry and Garot to be an acid, but they afterwards ascertained that it was neuter. It consists of nitrogen, carbon, hydrogen, sulphur, and oxygen. It may be obtained from white mustard seeds, previously deprived of the fixed oil by expression, by boiling them in water, evaporating the decoction to the consistence of honey, mixing the residue with 6 or 8 times its volume of anhydrous alcohol which precipitates various substances, then distilling off the alcohol, and setting aside the syrupy residue to crystallize. The crystals may be purified by repeated solution and crystallization in alcohol. (Berzelius, *Traité de Chimie.*) This principle, which has also been called *sinapin*, is considered by L. von Babo and Hirschbrunn to be the sulphocyanide of an alkaloid, to which they propose to confine the name of *sinapin*, and for which they give the formula $C_{32}H_{26}NO_{16}$. The *sulphocyanide of sinapin* is obtained from seeds, already so far exhausted by cold alcohol as to yield only a pale-yellow colour to that liquid by boiling them in alcohol of the sp. gr. 0·833, evaporating the liquor, and crystallizing. It has an appearance like that of crystallized sulphate of quinia, is soluble with difficulty in cold water and alcohol, but readily in both liquids when hot, and is nearly insoluble in ether. When boiled with alkalies, it yields an acid called *sinapic acid*. It is difficult to separate the organic base sinapin from it, because this is decomposed by alkalies. It does not appear that sulphocyanide of sinapin yields with synaptase the acrid principle developed in white mustard

From the foregoing account of the chemical relations of mustard, it is obvious that admixture with alcohol or the acids, or the application of a boiling heat, can only have the effect of impairing its medical virtues, and that the best vehicle, whether for external or internal use, is water at common temperatures.

Medical Properties and Uses. Mustard seeds swallowed whole operate as a laxative, and have acquired some reputation as a remedy in dyspepsia, and other complaints attended with torpid bowels and deficient excitement. The white seeds are preferred, and are taken in the dose of a tablespoonful once or twice a day, mixed with molasses, or previously softened and rendered mucilaginous by immersion in hot water. They probably act in some measure by mechanically stimulating the bowels. The bruised seeds or powder, in the quantity of a large teaspoonful, operate as an emetic. Mustard in this state is applicable to cases of great torpor of stomach, especially that resulting from narcotic poisons. It rouses the gastric susceptibility, and facilitates the action of other emetics. In smaller quantities it is useful as a safe stimulant of the digestive organs; and, as it is frequently determined to the kidneys, has been beneficially employed in dropsy. Whey, made by boiling half an ounce of the bruised seeds or powder in a pint of milk and straining, is a convenient form for administration. It may be given in the dose of a wineglassful repeated several times a day. But mustard is most valuable as a rubefacient. Mixed with water in the form of a cataplasm, and applied to the skin, it very soon produces redness with burning pain, which in less than an hour usually becomes insupportable. When a speedy impression is not desired, especially when the sinapism is applied to the extremities, the powder should be diluted with an equal portion of rye meal or wheat flour. Care should be taken not to allow the application to continue too long, as vesication with obstinate ulceration, and even sphacelus, may result. This caution is particularly necessary when the patient is insensible, and the degree of pain can afford no criterion of the sufficiency of the action. The volatile oil, which is powerfully rubefacient, and capable of producing speedy vesication, has been considerably used in Germany. For external application as a rubefacient, 30 drops may be dissolved in a fluidounce of alcohol, or 6 or 8 drops in a fluidrachm of almond or olive oil. To form a *sinapism* it has been recommended to mix 20 drops of the volatile oil with 3·5 drachms of glycerin and 5 drachms of starch. (See *Am. Journ. of Pharm.*, Nov. 1861, p. 569.) It has been given internally in colic, two drops being incorporated with a six-ounce mixture, and half a fluidounce given for a dose. (*Ibid.*, xi. 9.) In overdoses it is highly poisonous, producing gastro-enteric inflammation, and probably perverting the vital processes by pervading the whole system. Its odour is perceptible in the blood, and it is said to impart the smell of horseradish to the urine. A *spirit of mustard* may be prepared by macerating, for two hours, 250 parts of powdered black mustard with 500 parts of cold water, then adding 120 parts of alcohol of 86 per cent., and distilling over 120 parts of spirit. Though not so precise in composition as the alcoholic solution of the oil, it is more economical. (*Ann. de Thérap.*, 1864, p. 126.)*

seeds by water; but the authors state that another substance rich in sulphur has been ascertained by Simon to exist in white mustard seeds, which plays an important part in the production of the pungent matter. (See *Chem. Gaz.*, March 1, 1853, p. 81.)—*Notes to former editions.*

A practical application of the principles developed in the foregoing paragraphs has been suggested by M. Lebaigue, who proposes applying to one sheet of paper a concentrated solution of *myronate of potassa*, and to a second a concentrated solution of *myrosyne*, and drying them. When used the leaves are to be moistened and applied to the surface, one over the other. Volatile oil of mustard is formed by the reaction of the two principles, and the effects of a sinapism are obtained. (*Journ. de Pharm.*, Août, 1868, p. 118.)—*Note to the thirteenth edition.*

* *Rigollot's and Rueff's Mustard-papers.* In consequence of the various inconveniences attendant upon the application of ordinary mustard cataplasms, *mustard-papers* have

SODIUM.

Sodium.

Sodium, *Fr.;* Natrium, Natronmetall, *Germ.;* Sodio, *Ital., Span.*

Sodium is a peculiar metal, forming the radical of the alkali soda. It was discovered by Sir H. Davy in 1807, who obtained it in small quantity by decomposing the alkali by the agency of galvanic electricity. It was afterwards procured in much larger quantities by Gay-Lussac and Thenard, by bringing the alkali in contact with iron turnings heated to whiteness. The iron became oxidized, and the metallic radical of the soda was liberated. Since the discovery of a mode for obtaining aluminium in bars, by Deville, in 1854, the process for procuring sodium, which is the decomposing agent, has been very much improved and cheapened. (See *page* 101.) Sodium is now obtained on a large scale by igniting an intimate mixture of dry carbonate of soda, coal, and chalk.

Sodium is a soft, malleable, sectile solid, of a silver-white colour. It possesses the metallic lustre in a high degree, when protected from the action of the air, by which it is quickly tarnished and oxidized. Its sp. gr. is 0·97, fusing point about 200°, equivalent number 23·3, and symbol Na. Its chemical affinities resemble those of potassium, but are less energetic. Like potassium it has a strong attraction for oxygen. When thrown upon cold water it instantly fuses into a globule without inflaming, and traverses the surface in different directions with rapidity; on hot water it inflames. In both cases the water is decomposed, hydrogen is liberated, and a solution of soda generated. Like potassium also, if exposed with a bright surface to the air, it undergoes a slow combustion, which renders it luminous in the dark. It combines also with a larger proportion of oxygen than exists in soda, forming a *teroxide.* This oxide is always formed when the metal is burnt in the open air.

Sodium is a constituent of a number of important medicinal preparations, and is briefly described in this place as an introduction to these compounds. Its protoxide only is salifiable, constituting the alkali soda, which, united to acids, gives rise to a numerous class of compounds, called salts of soda. These are characterized by communicating to the blowpipe flame a rich yellow colour, and by not being precipitable by any reagent, except the metantimoniate of potassa. (See *page* 701.) Protoxide of sodium (*dry soda*) consists of one eq. of sodium 23·3, and one of oxygen 8=31·3. United with one eq of water 9, it forms hydrate of soda (*caustic soda*), weighing 40·3. It appears that the salts of sodium, long theoretically presumed to be isomorphous with those of lithium, have recently been proved to be so by a comparison of the crystals of the hyposulphites of the two alkalies. (*Journ. de Pharm.*, 4e sér., iv. 72.)

been contrived by M. Rigollot, in France, and Herr Rueff, in Germany, which aim to obviate these inconveniences.

1. *Rigollot's Mustard-paper* is prepared in the following manner. To a leaf of paper, sufficiently stiff, a layer of the flour of mustard, a millimeter in thickness, is attached by means of a solution of caoutchouc in the sulphide of carbon or a volatile oil. The solvent evaporates, leaving the flour of mustard entangled in a net of fibres adhering to the paper, and permeable by water as would be the meshes of a sieve. All that is necessary, when it is used, is to steep the mustard-paper, for 12 or 15 seconds, in water cold or warm, before applying it to the skin. Ninety grains of flour of mustard, employed in this method, are sufficient to redden strongly a surface of about four inches square. Mustard has its rubefacient power increased by depriving it of its fixed oil, which may be done by pressure, or by sulphide of carbon, which M. Rigollot prefers, while it keeps much better than that which retains its fixed oil. (*Journ. de Pharm.*, Oct. 1867, p. 269.)

2. *Rueff Mustard-paper.* This appears to have been prepared in the interests of the shop; for the mode of preparing it is not given in the highly laudatory notice of it contained in Buchner's *Neues Repertorium* (A. D. 1868, xvii. 182). It differs from Rigollot's preparation, is kept in well-closed stiff paper capsules, and retains its excellent properties unchanged. When to be used as a sinapism, all that is necessary is to cut off a piece of the required size, and having dipped it for a few seconds in lukewarm water, to apply it to the skin with some pressure, and, if needful, to confine it with a bandage. It is stated, in the communication concerning it, that it is likely to supersede mustard as a cataplasm. (*Note to the thirteenth edition.*)

The officinal combinations containing sodium are caustic soda, chloride of sodium, the solutions of soda and chlorinated soda, the acetate, arseniate, borate, carbonate, bicarbonate, phosphate, sulphate, sulphite, and valerianate of soda, and the tartrate of potassa and soda. The description of some of these combinations will immediately follow; and the remainder will be noticed, under their respective titles, in *Part* II. B.

SODÆ ACETAS. *U. S., Br.*

Acetate of Soda.

$NaO,C_4H_3O_3 + 6HO$. *Br.*

Terra foliata tartari, *Lat.;* Acétate de soude, *Fr.;* Essigsaures Natron, *Germ.;* Acetato di soda, *Ital.*

Acetate of soda, being obtained on a large scale from the manufacturing chemist, is properly placed in the catalogues of the Materia Medica of the U. S. and Br. Pharmacopœias.

Acetate of soda is prepared by the manufacturer of crude pyroligneous acid, for the purpose of being decomposed, so as to yield the officinal acetic acid, by the action of sulphuric acid. The steps of the process by which it is made from the crude acid have been given under the head of *Acidum Aceticum* (*page* 19).

Properties, &c. Acetate of soda is a white salt, crystallizing in long striated prisms, and possessing a sharp, bitterish, not disagreeable taste. Exposed to a dry air it effloresces slowly, and loses about 40 per cent. of its weight. It is soluble in about 3 parts of cold water, and in 24 of alcohol. Subjected to heat it undergoes first the aqueous and then the igneous fusion, and is finally decomposed; the residue being a mixture of carbonate of soda and charcoal. By the addition of sulphuric acid it is decomposed, the acetic acid being liberated, known by its acetous odour, and sulphate of soda formed. The salt should be perfectly neutral to test paper, and not precipitated by chloride of barium, nitrate of silver, or bichloride of platinum. The non-action of these tests shows the absence of sulphates, chlorides, and the salts of potassa. For the proper action of the nitrate of silver test, the solution should be dilute; as, if it be strong, there will be a crystalline precipitate of acetate of silver, which dissolves on the addition of water. Acetate of soda, when crystallized, consists of one eq. of acetic acid 51, one of soda 31·3, and six of water 54 = 136·3.

Medical Properties and Uses. Acetate of soda is diuretic, and possesses generally the same medical properties as acetate of potassa, to which article the reader is referred. It is, however, more convenient for exhibition than the latter salt, as it is not deliquescent. The dose is from a scruple to two drachms. It is employed principally to yield acetic acid by the action of sulphuric acid.

SODÆ BORAS. *U. S.*

Borate of Soda.

Off. Syn. BORAX. *Borax.* $NaO,2BO_3 + 10HO$. *Br.*

Borate de soude, Borax, *Fr.;* Boraxsaures Natron, Borax, *Germ.;* Borace, *Ital.;* Borax, *Span.;* Boorak, *Arab.*

Borax was known to the ancients, but its chemical nature was first ascertained by Geoffroy in 1732. It exists native, and may be obtained by artificial means. It occurs in several localities in Europe, in Peru, and in beds, associated with borate of lime, in the district of Iquique, in the Republic of Ecuador. This mineral (*cinkalzite*) which has become an article of commerce, and is considerably used as a substitute for borax, contains, according to T. L. Phillipson, 34 per cent. of water, 11·95 of soda, 14·45 of lime, 34·71 of boracic acid, 1·34 of

chlorine, 1·10 of sulphuric acid, 0·60 of silica, and 2 of sand; and may be considered as a compound essentially of one eq. of crystallized borate of soda and two of borate of lime, more two eqs of water. (*Chem. News*, Oct. 5, 1861, p. 183.) It is said also to contain usually some iodine and bromine. (*G. Sims.*) Borax is found abundantly in certain lakes of Thibet and Persia, from which it is obtained by spontaneous evaporation. The impure borax, called in commerce *tincal* or *crude borax*, concretes on the borders of these lakes. As thus obtained it is in the form of crystalline masses which are sometimes colourless, sometimes yellowish or greenish, and always covered with an earthy coating, greasy to the touch, and having the odour of soap. The greasy appearance is derived from a fatty matter, saponified by soda. The tincal is transferred to the seaports of India, especially Calcutta, from which it is exported to this country in chests. Besides Indian tincal, there is another commercial variety of borax which comes from China, and which is partially refined. Both varieties require to be purified before being used in medicine or the arts.

A new and abundant source of borax has recently been developed within the limits of the United States. The existence of a borax lake in California was first made known by Dr. J. A. Veatch, who visited it in September, 1856, and, upon examining its waters, found borax among its constituents. The borax lake is a small offset of a large sheet of water, called *Clear Lake*, which is situated in the midst of a volcanic region, about 36 miles from the Pacific, and about 100 miles north of San Francisco. The smaller lakelet is separated from the larger by a low ridge of volcanic materials loosely massed together. It is of variable dimensions according to the season, being sometimes dry, at others filled with water to the extent of about a mile in length and half a mile in breadth. In September, 1863, the water, being analyzed by Mr. T. E. Moore, was found to contain in a gallon 2401·56 grains of solid matter, of which about one-half was common salt, one-quarter carbonate, and the remainder chiefly borate of soda, equivalent to 535·08 grains of the crystallized biborate to the gallon. The borax, being the least soluble of the saline constituents, from time to time, as the water becomes saturated, crystallizes out, and being deposited at the bottom of the lake, has accumulated there in large quantities. The crystals of borax, from the minutest speck up to a diameter of two or three inches, intermixed with blue mud, form a layer at the bottom of the lake of variable thickness, but 18 inches in one place that was examined. This deposit forms an apparently inexhaustible supply of borax, for as fast as removed in one place it is deposited in another by crystallization from the water, which, supplied from the volcanic regions around, promises to continue furnishing the borax for an indefinite period. Already the lake has supplied large quantities of borax to commerce. Iron coffer dams are sunk to the bottom of the lake, the water pumped out, and the mixed mud and crystals removed. The crystals are picked out, and the earth, which is strongly impregnated with borax, is lixiviated, and the solution thus obtained evaporated in boilers till crystals form. At the last accounts 4000 pounds of the salt are collected daily, and it is said that the quantity will be greatly increased on the completion of the works. (Prof. J. D. Whitney, *Silliman's Journ.*, March, 1866; and D. J. Macgowan, *Am. Journ. of Pharm.*, March, 1867, p. 155.)

Purification. The method of refining borax was originally possessed as a secret by the Venetians and Dutch, but is now practised in several European countries. The process pursued in France, as reported by Robiquet and Marchand, is as follows. The tincal is placed in a large wooden vessel, and covered to the depth of three or four inches with water; in which state it is allowed to remain for five or six hours, being agitated from time to time. Slaked lime is now added, in the proportion of 1 part to 400 of the impure salt; and the whole, being thoroughly mixed, is allowed to remain at rest till the succeeding day. The salt is next separated by means of a sieve, the crystals being crumbled between the hands, and placed so as to drain. The object of this treatment is to separate the soapy matter, with which the lime forms an insoluble soap; and at

the same time sulphate of soda and chloride of sodium are removed, with only a minute loss of the borax. The borax being drained is next dissolved, by the assistance of heat, in two and a half times its weight of water, and the solution treated with one-fiftieth of its weight of chloride of calcium, in order to complete the separation of the soapy matter; after which it is strained through a coarse bag. The liquor is then concentrated by heat, and run into wooden vessels, lined with lead, having the shape of an inverted quadrangular pyramid. If care be taken that the cooling proceed very gradually, distinct crystals will be obtained, such as are found in commerce; otherwise, crystalline crusts will be formed. The Chinese borax is purified in a similar manner; but, being less impure than the common tincal, does not require to be washed.

Preparation of Artificial Borax. Large quantities of borax are now made by the direct combination of *native boracic acid* with soda. The acid is found abundantly in the crater of Vulcano, one of the Lipari Islands; but principally in a volcanic region of Tuscany, occupying a space of ten or twelve miles. Within this region are found numerous hillocks and fissures, the latter of which emit hot aqueous vapour, containing boracic acid and certain gases. Around one or several of these fissures, a circular basin of masonry is built, which is filled with water, and called a lagoon. By the jets of vapour, constantly breaking through it, the water becomes gradually impregnated with boracic acid, and heated. A series of such lagoons are made to communicate with each other on the declivity of a hill, and the lowest to discharge itself into a reservoir, where the solution is allowed to rest, and deposit mechanical impurities. From this reservoir the solution is made to pass into leaden evaporating pans, heated by the natural vapour, where it receives sufficient concentration to fit it for being conducted into wooden tubs, where it is allowed to cool and crystallize. The crude acid, thus obtained, contains, on an average, 84 per cent. of boracic acid; the impurities consisting chiefly of alum, the double sulphate of ammonia and magnesia, and sulphate of lime. The product of the Tuscany lagoons in 1855 was over 1800 tons. (A. Péchiney-Rangot, *Journ. de Pharm.*, xxviii. 358.) The crude acid is converted into borax by dissolving it to saturation in a solution of carbonate of soda, heated by steam; and the liquor, after boiling, is allowed to stand for ten or twelve hours. It is then drawn off into wooden vessels lined with lead, where it crystallizes. The impure crystals, thus obtained, are refined by dissolving them in water heated by steam, adding carbonate of soda to the solution, and crystallizing. The merit of introducing the process for obtaining artificial borax belongs to Cartier and Payen, who succeeded in establishing its manufacture in France. According to Dr. Veatch, boracic acid exists in the sea-water on the coast of California.

Another method of neutralizing the Italian boracic acid is now in practice in England. Instead of combining the acid and alkali in solution, the manufacturer mixes the acid in a solid state with a proper proportion of soda ash, and exposes the mixture to the heat of a reverberatory furnace; provision being made for the collection of a large quantity of ammonia, which is always present in the crude acid, and escapes during the process. The remaining operations are similar to those performed in the preparation of carbonate of soda from the cake. (*Am. Journ. of Pharm.*, July, 1867, p. 339; from the *Druggists' Circular*, Feb. 1867.)

Properties. Borax is a white salt, generally crystallized in flattened hexahedral prisms, terminated by triangular pyramids, and possessing a sweetish, feebly alkaline taste, and an alkaline reaction. It dissolves in twelve times its weight of cold, and twice its weight of boiling water. Exposed to the air it effloresces slowly, and the surface of the crystals becomes covered with a white powder. Subjected to a moderate heat it undergoes the aqueous fusion, swells considerably, and finally becomes a dry porous mass, with loss of half its weight. Above a red heat it melts into a limpid liquid, which, after cooling, concretes into a transparent solid, called *glass of borax*, much used as a flux in assays with the blowpipe. Borax has been found, in the English market, adulterated to the ex-

tent of 20 per cent. with phosphate of soda. This may be detected by exposing the suspected borax to the heat of a drying room for a few hours, when the phosphate, if present, will effloresce, and may be picked out.

Borax has the property of rendering cream of tartar very soluble in water, and forms a combination with it called *soluble cream of tartar*, which is sometimes used in medicine. This preparation is made by boiling 6 parts of cream of tartar and 2 of borax in 16 of water for five minutes, allowing the solution to cool, and then filtering to separate some tartrate of lime. Soluble cream of tartar attracts moisture from the air, and is soluble in its own weight of cold, and half its weight of boiling water. A similar preparation may be made by substituting boracic acid for the borax. *Boracic acid soluble cream of tartar* was directed by the French Codex of 1837, and was made by the following formula. Four hundred parts of cream of tartar and 100 of the acid are dissolved in a silver basin, at the boiling temperature, in 2400 parts of water. The solution is kept boiling until the greater part of the water is consumed. The fire is then moderated, and the solution continually stirred while the evaporation proceeds. When the matter has become very thick, it is removed by portions, which are flattened in the hand, completely dried by the heat of a stove, powdered, and kept in well-stopped bottles. This form of soluble cream of tartar is more soluble than that made with borax. According to M. E. Robiquet, in order to obtain soluble cream of tartar, made with boracic acid, of good quality, it is necessary to use a large quantity of water, and to boil for a long time. By proceeding thus, the boracic acid undergoes a molecular modification, equivalent to a change from the crystallized to the vitreous condition, and a preparation, readily and totally soluble in cold water, is ensured. The product should not be powdered, but kept in large grains. (*Journ. de Pharm.*, xxi. 197.)

Composition. Borax consists of two eqs. of boracic acid 69·8, and one of soda 31·3 = 101·1. It ordinarily crystallizes in prisms, and contains ten eqs. of water (*prismatic borax*); but a variety of the salt exists, which crystallizes in octohedrons, and contains only five eqs. of water (*octohedral borax*). The latter is obtained in the artificial production of borax, by crystallizing from a concentrated solution at a temperature between 174° and 133°. When a solution of borax is evaporated at 212°, the salt is left as a transparent, amorphous, brittle mass, containing four eqs. of water. (*Schweitzer.*) In composition borax is a *biborate*, though sometimes called a subborate on account of its possessing an alkaline reaction.

Boracic acid may be obtained artificially by decomposing a hot saturated solution of borax with sulphuric acid, which unites with the soda to form sulphate of soda, and sets free the acid. As thus obtained it is in white, shining, scaly crystals, characterized by the property of imparting a light-green colour to the flame of burning alcohol. Boracic acid consists of one eq. of boron 10·9, and three of oxygen 24 = 34·9.* *Boron* is a non-metallic element, which, like carbon, exists in three allotropic states, called amorphous, graphitoidal, and crystallized boron, representing severally charcoal, graphite, and diamond. Crystallized boron is very brilliant, and of different colours, from garnet-red to a nearly colourless honey-yellow. Its density is 2·68, and hardness very great. Wöhler and Deville distinguish three varieties of crystals, containing from 2 to 4 per cent. of carbon; and one specimen, in addition to carbon, about 7 per cent. of aluminium. The hardest variety was as hard as diamond. (See *Chem. Gaz.*, Aug. 1, 1857, p. 281.)

* *Reactions of Boracic Acid.* From the researches of M. C. Tissier, it appears that boracic acid, in boiling solution, is capable of dissolving the protoxides of calcium, magnesium, manganese, iron, cobalt, nickel, zinc, and cadmium, but not those of copper, lead, or tin, nor the sesquioxides of aluminium, chrome, or iron. In other words, it dissolves the protoxides of all the metals which decompose water in the presence of acids, and is without action on those of other metals, as well as on all the higher oxides, such as sesquioxides and binoxides. It dissolves only one of the insoluble metallic sulphurets, namely, the sulphuret of manganese. (*Journ. de Pharm.*, Juillet, 1858, p. 98.)

Medical Properties. Borax is a mild refrigerant and diuretic. It is supposed also to exercise a specific influence over the uterus, promoting menstruation, facilitating parturition, and favouring the expulsion of the placenta. Dr. Binswanger denies its specific power of exciting uterine contractions, or promoting menstruation. Nevertheless, Dr. Daniel Stahl, of Indiana, has found it useful in dysmenorrhœa, occurring in sanguineous constitutions, venesection being premised. He gives it in doses of about nine grains every two hours, in a tablespoonful of flaxseed tea, for two days before the time of the expected return of the menses. Virey deemed it aphrodisiac; and, according to Dr. J. C. Hubbard, it is eminently so when used in the form of enema. Binswanger considers borax as the best remedy that can be used in nephritic and calculous complaints, dependent on an excess of uric acid. It probably acts in such cases as an alkali, the soda of the salt neutralizing the uric acid occurring in the urinary passages, and the boracic acid being set free. The dose is from thirty to forty grains. In infantile diarrhœa, unattended by lesions of the intestinal mucous membrane, M. Bouchut has found borax peculiarly efficacious, given in the form of enema, made by dissolving from two to five drachms in four fluidounces of water. Cream of tartar is conveniently rendered more soluble by borax or boracic acid, when it is desirable to administer it in large quantities. Externally the solution of borax is used as a wash in scaly eruptions. A solution, formed by dissolving a drachm of the salt in two fluidounces of distilled vinegar, has been found, both by Dr. Abercrombie and Dr. Christison, an excellent lotion for ringworm of the scalp. Borax has been employed with good effect by Dr. Brinton in an inveterate case of cracked tongue, applied as a lotion, made by dissolving two scruples of borax in an ounce of glycerin, and four fluidounces of water. This salt is very much used as a detergent in aphthous affections of the mouth in children. When employed for this purpose, it is generally applied in powder, either mixed with sugar in the proportions of one part to seven, or rubbed up with honey. (See *Mel Boracis.*)

Borax is used in the arts for soldering metals, its effect being to keep the surfaces free from oxidation. It is said also to have come into use, in some places, in washing clothes, as a substitute for soap, which it resembles in its effects, while it does not disturb the colours. It is used in very small proportion. (*Neues Repertorium*, A. D. 1864, xiii. 423.)

SODÆ CARBONAS. *U. S., Br.*

Carbonate of Soda.

$NaO,CO_2 + 10HO$. *Br.*

Carbonate de soude, *Fr.;* Einfach Kohlensaures Natron, *Germ.;* Carbonato di soda, *Ital.;* Carbonato de soda, *Span.*

In the U. S. Pharmacopœia this salt has always been placed in the list of the Materia Medica; the crystallized carbonate of soda, obtained on a large scale by the manufacturing chemist, being sufficiently pure, without further preparation, for medicinal use; and the same position is given to it in the British Pharmacopœia.

Before entering upon the consideration of the carbonate of soda, we shall speak generally of the sources of the alkali soda. These may be divided into the natural and artificial. The natural sources are the minerals of native soda, and certain marine plants which yield the alkali in their ashes; the artificial are certain salts which furnish it by chemical decomposition.

Native soda, sometimes called *natron*, is found chiefly in Hungary, Egypt, and South America, and exists, in these countries, either in the earth of the surface, which often exhibits a saline efflorescence, or in solution in small lakes, from which it is extracted by taking advantage of the drying up of the water during the heats of summer. The native soda from Egypt, called *trona*, is a *sesquicarbonate;* while that from South America is less carbonated. Native

soda, in the form of sesquicarbonate, has been found in a soda lake in the territory of the Nizam, in Hindostan. Dr. Barth, in his *Travels in Africa*, states that natron is largely collected on the shores of Lake Tsad, and in some other localities in Negroland or Central Africa. (*Am. ed.*, 1857, i. 312, and ii. 63–8.) A similar product exists abundantly in low places along the sea-coast of Arabia, near Aden. (R. Haines, *Pharm. Journ.*, July, 1863.)

Impure soda, derived from the ashes of plants growing on the surface or borders of the sea, is called barilla or kelp, according to the character of the plants incinerated. Barilla is obtained from several vegetables, principally belonging to the genera *Salsola*, *Salicornia*, and *Chenopodium*. In Spain, Sicily, and some other countries, these plants are cultivated for the purpose of yielding soda by their combustion. When ripe, they are cut down, dried, and burnt in heaps. The ashes form a semi-fused, hard, and compact saline mass, which is broken up into fragments by means of pickaxes, and thrown into commerce. Kelp, called *varec* in France, is procured by the incineration of various kinds of sea-weeds, principally the algæ and fuci, which grow on the rocky coasts of many countries. The Orkneys and Hebrides, and the rocky coasts of Wales, Scotland, and Ireland furnish large quantities of these weeds. The plants are fermented in heaps, then dried, and afterwards burnt to ashes in ovens roughly made of brick or stone, and built in the ground. The alkali in the ashes melts, and forms the whole into one solid mass. When cold, it is broken up with iron instruments into large heavy masses, in which state it is found in commerce. About twenty-four tons of sea-weeds produce one of kelp.

Barilla, when of good quality, is in hard, dry, porous, sonorous, grayish-blue masses, which become covered with a saline efflorescence on exposure. It possesses a peculiar odour and an alkaline taste. *Spanish barilla* contains from 25 to 40 per cent. of carbonated alkali; the residue being made up of sulphate of soda, sulphuret and chloride of sodium, carbonate of lime, alumina, silica, oxidized iron, and a small portion of charcoal which has escaped combustion. Before the introduction of artificial soda, barilla formed the source of the crystallized carbonate employed in medicine. At present it is principally used in the manufacture of soap.

Kelp is in hard, vesicular masses, of a dark-gray, bluish, or greenish colour, sulphurous odour, and acrid, caustic taste. It is still less pure than barilla, containing only from 5 to 8 per cent. of carbonated soda; the rest being made up of a large proportion of the sulphates of soda and potassa, and the chlorides of potassium and sodium, a small quantity of iodide of sodium, and insoluble and colouring matters. Large quantities of kelp were formerly manufactured in Great Britain and the neighbouring islands, particularly the Orkneys; but the demand and production have greatly fallen off, since the introduction of artificial soda at a comparatively low price. At present kelp is used principally in the manufacture of iodine. (See *Iodinium*.)

Artificial Soda. This is made from common salt by two steps; first, by converting the salt by sulphuric acid into sulphate of soda, and secondly, by decomposing the sulphate by carbonate of lime and charcoal at a high temperature, so as to yield carbonate of soda. The sulphate, first dried, is mixed with its own weight of ground limestone, and half its weight of small coal, ground and sifted, and the whole is heated in a reverberatory furnace, where it fuses, and forms a black mass called *black ash*, *soda ball*, or *British barilla*. The coal, at the temperature employed, converts the sulphate of soda into sulphuret of sodium. This reacts with the limestone, so as to form sulphuret of calcium and carbonate of soda (NaS and $CaO,CO_2 = CaS$ and NaO,CO_2). If this compound were digested in water, sulphuret of sodium and carbonate of lime would be reproduced. To prevent this result a large excess of lime is used, which gives rise to the formation of an oxysulphuret of calcium ($3CaS,CaO$), which is insoluble in water, and without action on carbonate of soda. British barilla contains about 36 per cent. of alkali, imperfectly carbonated on account of the high heat used; the remainder being principally oxysulphuret of calcium, caustic

lime, and coaly matter. It is next digested in warm water, which takes up the alkali and other soluble matters, and leaves the insoluble impurities, called *soda waste*, which is now largely utilized in the manufacture of hyposulphite of soda. (*Chem. News*, Sept. 28, 1861, p. 174.) The solution is evaporated to dryness, and the mass obtained is calcined with one-fourth of its weight of sawdust, in order to convert the alkali fully into carbonate, by means of the carbonic acid resulting from the combustion of the sawdust. The product is redissolved in water, and the solution evaporated to dryness. The alkali, in this stage of its purification, contains about 50 per cent. of carbonate of soda, and is called *soda-ash*. It is brought to the state of crystallized carbonate of soda, by dissolving it in water, straining the solution, evaporating it to a pellicle, and setting it aside to crystallize. On the subject of the products of the soda manufacture, see an elaborate paper by John Brown, Esq., in the *Philos. Mag.* for Jan. 1849.

The process here described, for obtaining soda from common salt, was discovered in 1784 by Leblanc; and the first manufactory for procuring it on a large scale was established in 1790, near Paris, by Leblanc and Dizé. The process is pursued on an immense scale in Great Britain, especially at Liverpool and Glasgow, and produces soda at so small a cost, that barilla and kelp are nearly superseded as sources of the alkali.

A new process for manufacturing artificial soda from sulphate of soda has been proposed by M. Emile Kopp, and has been successfully carried into operation on a large scale, near Manchester, England. It consists in decomposing the sulphate by sesquioxide of iron and coal. The advantages claimed for this process are that the whole of the sulphur of the sulphate may be recovered, instead of being lost in the waste oxysulphuret of calcium of the old process, and that it is more independent of the skill of the workmen. (See *Journ. de Pharm.*, Nov. 1856, p. 360.)

Mr. A. G. Hunter, of Rockcliff Hall, near Flint, has made a discovery which bids fair materially to modify Leblanc's method of preparing carbonate of soda. It is known that caustic baryta will decompose sulphate of soda, uniting with the acid, and leaving caustic soda in solution. But baryta is so costly as to render this property practically nugatory. Mr. Hunter's discovery consists in the fact, that caustic lime has the same effect, if aided by a pressure considerably exceeding that of the atmosphere, brought to bear on the solution of the sulphate of soda, after the addition of the lime. The caustic soda thus obtained in solution may be converted into the carbonate by direct union with carbonic acid. (*Am. Journ. of Pharm.*, March, 1866, p. 172.)

Another source of this carbonate has lately been found in *cryolite*, a mineral existing in great abundance on the coast of Greenland, and largely imported into this country by a manufacturing company, which enjoys to a certain extent a monopoly of the mineral under the Danish authorities. Cryolite consists mainly of a double fluoride of aluminium and sodium, containing in 100 parts 13 of aluminium, 34 of sodium, and 53 of fluorine. Carbonate of soda is obtained by boiling cryolite with lime, whereby the fluoride of calcium is formed, which, being insoluble, is deposited, and alumina and soda combined in solution. The soda is converted into carbonate by passing carbonic acid through the solution; and the alumina, separated from the soda, becomes insoluble, and is deposited. (*Am. Journ. of Pharm.*, Jan. 1868, p. 71.) Cryolite is also largely used in Denmark and Germany in the preparation of carbonate of soda and of alumina, the latter of which is employed in the manufacture of alum and aluminium. The cryolite is mixed thoroughly with chalk, in the state of powder, and the mixture is calcined. The fluorine combines with the calcium of the lime, which gives its oxygen to the sodium and aluminium, converting them into soda and alumina. The soda is extracted by lixiviation, and carbonic acid passed through the solution. The carbonate of soda thus formed is obtained by evaporation and crystallization. (*Ibid.*, May, 1863, pp. 244 and 255.)*

* *Cryolite.* Besides the preparation of carbonate of soda, cryolite is employed for other important purposes. Its only known locality, at least in large amount, is Greenland,

The different kinds of impure carbonate of soda, whether barilla, kelp, or soda-ash, being exceedingly variable in composition, it is important to have a ready method of determining the quantity of real carbonated alkali which they contain. The mode in which this is done, by means of an instrument called an alkalimeter, has been already explained. (See *page* 700.) These various forms of carbonated soda are largely consumed in dyeing and bleaching, and in the manufacture of soap and glass.

The following are descriptions of the different grades of artificial soda, known under the names of British barilla, soda-ash, and carbonate of soda.

British barilla, so called to distinguish it from Spanish barilla, which has its source in the ashes of maritime plants, is a blackish-brown substance, becoming darker by exposure to the air. When broken it exhibits an imperfect metallic lustre, and a close striated texture. Its taste is hepatic and caustic. By exposure to a moist atmosphere, it becomes covered with a yellow efflorescence, and quickly falls to powder, with disengagement of heat and sulphuretted hydrogen; at the same time increasing in weight by the absorption of carbonic acid and water.

Soda-ash is in white or gray compact masses, and contains about half its weight of foreign salts, consisting principally of chloride of sodium and sulphate of soda.

Carbonate of soda is a colourless salt, possessing a disagreeable taste and alkaline reaction, and crystallizing usually in large oblique rhombic prisms, which speedily effloresce when exposed to the air. When heated it undergoes the aqueous fusion; and, if the heat be continued, it dries and finally suffers the igneous fusion. Of the crystallized salt, 100 parts of water dissolve 60 at 57°, 833 at 97°, its temperature of maximum solubility, and 445 at 219°, or the boiling point of the solution. (*Payen.*) This salt presents other anomalies in solubility, as ascertained by M. Henri Lœwel. Carbonate of soda is insoluble in alcohol. The most usual impurities in it are sulphate of soda and common salt, which may be detected by converting it into a nitrate, and testing separate portions of this severally with chloride of barium and nitrate of silver. Common salt is seldom entirely absent, but good specimens are free from sulphate of soda. When badly prepared, it is liable to contain sulphuret of sodium, which may be detected by the production of the smell of sulphuretted hydrogen upon dissolving the salt in water. Carbonate of soda is incompatible with acids, acidulous salts, lime-water, muriate of ammonia, and earthy and metallic salts. It consists of one eq. of carbonic acid 22, and one of soda 31·3 = 53·3. When fully crystallized it contains ten eqs. of water 90, giving as the number representing the crystallized salt 143 3. It is thus perceived that this salt, when perfectly crystallized, contains nearly two-thirds of its weight of water; but the quantity actually present in it, as found in the shops, is variable, being dependent on the extent to which it may have undergone efflorescence.

Medical Properties and Uses. Carbonate of soda is antacid, antilithic, and resolvent. It is given principally in diseases attended with acidity of the stomach; such as gout, uric acid gravel, and certain forms of dyspepsia. It is more frequently exhibited than carbonate of potassa; as, from its less acrid taste, it

where it is found near Cape Farewell, existing in beds, of which one is said to be 80 feet thick and 300 long. It is said that the manufacturing company referred to in the text, the "Pennsylvania Salt Company," imported in 1865 and 1866 thirteen cargoes, amounting to 9000 tons, into Philadelphia, and in the year 1867 were expected to import 8000 tons. It is a handsome mineral, hard, brittle, and translucent, sometimes almost transparent, but generally of a frosty whiteness, which has probably suggested its name of *cryolite* or *kryolite*, from the Greek κρυος, frost. Though homogeneous in great degree, it exhibits here and there in its substance dark spots, sometimes mere specks, sometimes of considerable size, which appear to be crystalline centres of substances mixed with it at the time of solidification, such as galena, sulphuret of lead, carbonate of iron, copper and iron pyrites, &c. It is employed in the making of soap, in the preparation of sulphate of alumina, and in the formation of a beautiful variety of glass, which is made by melting one part of it with from two to four parts of pure silex. (Evan T. Ellis, *Proceed. of Am. Pharm. Association*, 1867.)—*Note to the thirteenth edition.*

is more easily taken. It has also been recommended in hooping-cough, scrofula, and bronchocele. In the latter disease, Dr. Peschier, of Geneva, considered it more efficacious than iodine. It is also employed with advantage, internally and externally, in skin diseases, especially those of a papulous and scaly character. A lotion suitable for these cases may be formed by dissolving from two to three drachms of the carbonate in a pint of water. For a bath, from eight to sixteen ounces of the salt may be dissolved in the necessary quantity of water. A suitable ointment may be made by mixing from eight to sixty grains with an ounce of lard, according to the character of the affection. Carbonate of soda is given in doses of from ten grains to half a drachm, either in powder, or dissolved in some bitter infusion. In consequence of the variable state in which it exists in the shops, as to the amount of water of crystallization which it contains, the dose cannot be indicated with precision. It is on this account that the salt is most conveniently administered in the dried state, which admits of its being given in the pilular form. (See *Sodæ Carbonas Exsiccatus.*) When taken in an overdose it acts as a corrosive poison. The best antidotes are the fixed oils, acetic acid, and lemon-juice.

SODÆ HYPOSULPHIS.

Hyposulphite of Soda. Br. Appendix.

Hyposulphite of Soda crystallized, $NaO,S_2O_2+5HO=124$. *Br.*

This salt was introduced into the British Pharmacopœia as a test, and for the formation of the *Volumetric Solution of Hyposulphite of Soda.* It is readily prepared, according to Walchner, by mixing a pound of dry carbonate of soda, in fine powder, with five ounces of sulphur, heating the mixture gradually in a porcelain vessel until the sulphur melts, and stirring the agglutinated mass, still kept hot, in order that every portion of it may come in contact with the air. The sulphuret of sodium, first formed, is thus converted into sulphite of soda. This is dissolved in water, and the filtered solution, being boiled with sulphur, becomes one of hyposulphite of soda, from which, after filtration and concentration, the salt is deposited in crystals. It may be obtained also by digesting the solution of sulphite of soda, at a high temperature but short of ebullition, with finely divided sulphur. The sulphurous acid (SO_2) takes an additional eq. of sulphur, becoming hyposulphurous (*dithionous*) acid (S_2O_2), which combines with the soda to form the hyposulphite (NaO,S_2O_2). This acid exists only in combination; and its salts were formerly considered simply as sulphuretted sulphites.

Properties. Hyposulphite of soda is in large colourless transparent crystals, of a mild, saline, sulphurous taste, freely soluble in water, and insoluble in alcohol. Its solution dissolves chloride of silver and all other insoluble compounds of that metal, except the sulphuret, and that resulting from the decomposition of a silver salt by light. Though without action on iodide of potassium, it dissolves iodine, decomposes iodic acid with the liberation of iodine, and destroys the blue colour of iodide of starch. (*Brande and Taylor.*) In dissolving iodine it forms with it iodide of sodium and tetrathionate of soda; as represented by the formula $2(NaO,S_2O_2)+I=NaI+NaO,S_4O_5$. It dissolves also sulphate and iodide of lead, and sulphate of lime much more freely than water. (*Journ*

de Pharm., Avril, 1864, p. 363.) Its relations to iodine render it valuable as a means of estimating the quantity of free iodine, for which purpose it is used in the Br. Pharmacopœia, in the form of a *volumetric solution*. In consequence of its peculiar solvent properties it is much used in photography. The daguerreotypists employ it for the purpose of dissolving the sensitive coating of iodide of silver from the plate, after the action of the light, and thus fixing the image already formed. For an account of the several tests of this salt, the reader is referred to the *Chemical News* (Dec. 12, 1863, p. 283). One of the most delicate is that of iodine and starch. The blue colour produced by the mixture of very small quantities of these two substances in solution is instantly discharged by a solution containing a trace of the hyposulphite. Mr. M. Carey Lea has discovered a new test in ruthenium. When a solution of a salt of this metal, made alkaline with ammonia, is boiled with the hyposulphite, it gradually becomes rose-coloured, and ultimately of a rich carmine, which in strong solution becomes almost black; and then, if diluted, the shade is magnificent, rivalling the aniline red in richness. (*Am. Journ. of Sci. and Arts*, Sept. 1867, p. 222.)

Medical Properties. Hyposulphite of soda has recently come into use, in consequence of its extraordinary powers in destroying the life of the lower organic beings, such as have been found, through microscopic investigation, to infect various parts of the human system, and are sometimes the cause of troublesome, if not serious disease. When taken internally it appears to have deoxidizing powers, probably through the passage of the hyposulphurous into sulphuric acid. It has been found, in its action on the urine, to diminish urea and increase uric acid, to increase the sulphates, and to cause the presence of sugar and oxalic acid in the urine. (Kletzinsky, *Ann. de Thérap.*, A. D. 1860, p. 109.) The use of this salt has been suggested, by Dr. G. Polli, in various diseases supposed to be dependent on the presence of substances in the blood which act as ferments. Along with its destructive action on microscopic fungi, it has an extraordinary power of arresting fermentation; and with those who believe that this process is essentially connected with organic growths, the two properties may be considered identical. The theory is plausible, and to a certain extent is supported by the experiments of Dr. Polli. Low febrile and malignant diseases, purulent infections, and the contagious exanthemata are included in the category referred to; and the medicine might very properly be tried in these affections, in connection with the ordinary remedies. Many reports have been made of its favourable influence in diseases denominated zymotic. In the U. States it has been used with much success in malarial fevers. Among others, Dr. W. H. Baxter, of Moscow, Iowa, seems to have been peculiarly successful, having given the remedy exclusively in more than 100 cases of intermittent and remittent fever, without a single failure. (*Am. J. of Med. Sci.*, Oct. 1866, p. 584.) With a view to its poisonous influence on the sarcina ventriculi which attends yeasty vomiting, it has been employed in that complaint; and, as a local application, it may be used in all the parasitic affections of the skin and mouth. It may be given in the dose of from ten to twenty grains three times a day, simply dissolved in water, or in the form of syrup. For external use a drachm may be dissolved in a fluidounce of water. As the effects of this salt proceed from its acid constituent, other hyposulphites may be employed for the same purposes; and *hyposulphite of lime* has been recommended. For the mode of preparing the latter salt, the reader is referred to an article in the *Am. Journ. of Pharm.* for May, 1863 (p. 223). W.

SODÆ NITRAS. *Br.*

Nitrate of Soda.

NaO,NO_5. A native salt, purified by crystallization from water. *Br.*

This salt, called also *cubic nitre*, which has been recognised as officinal in the British Pharmacopœia, because necessary in the preparation of their *arseniate of soda*, must now be treated in this part of the Dispensatory, which

embraces all the strictly officinal medicines recognised as such in the U. S. or British Pharmacopœias. We, therefore, bring hither the following article by the late Dr. Bache from the third part of the work, where it has long held a place.

Nitrate of soda is imported from S. America, where it is found naturally in the desert of Atacama and elsewhere in Peru, forming beds of vast extent. Attempts were made between 1820 and 1830 to export it to England and the United States; but the cargoes were unsalable. Soon afterwards, however, its value became known; so that at present large quantities are exported from Peru, being consumed in the manufacture of sulphuric and nitric acids, and as a fertilizer. The salt has also been found largely in Brazil, in the Province of Bahia, near the river San Francisco. (*Am. Journ. of Pharm.*, Nov. 1861, p. 502.) For a particular account of the nitrate of soda deposits of Peru, in a commercial point of view, see *Ibid.*, March, 1862, p. 263.

The crude salt, as it comes from Peru, is in saline lumps, rather soft and friable, and damp on the surface. It is distinguished into varieties according to its colour and state of aggregation, as *white compact, yellow, gray compact, gray crystalline, white crystalline*, and varies very much in purity, containing from 85 to only 20 per cent. of the pure salt. Some of the varieties contain iodine. The impurities consist of common salt, sulphate and carbonate of soda, and chloride of calcium. Occasionally borate of lime, associated with borate of soda, is found under the beds of the nitrate.

Arrangements have been made for treating the crude nitrate, so as to deliver it to commerce in a state of great purity. Exposure of the mineral to an open fire, which seems to have been first employed, has been entirely superseded by mechanical methods aided by steam, to prepare it for the subsequent steps of solution, crystallization, and desiccation. The Peruvian nitre, prepared by the "Nitre Association of Tarapaca," the province in which the mineral exists, never contains more than 0·5 or 0·667 per cent. of impurities. It is white, pearly, dry, and light; and does not require to be refined for the practical uses to which it is applied. (Thiercelin, *Journ. de Pharm.*, Juin, 1868, p. 439.)

Nitrate of soda, when pure, is a white salt, crystallizing in rhomboidal prisms, and having a sharp, cooling, and bitter taste. It attracts moisture slightly from the air, and dissolves in about twice its weight of water, at 60°. Like nitrate of potassa, it deflagrates when thrown on the fire; but is distinguished by giving rise to an orange-yellow flame, and by the rhomboidal shape of its crystals, those of nitre being long six-sided prisms. According to the Br. Pharmacopœia, it evolves ruddy flames when warmed in a test tube with sulphuric acid and copper wire. "The solution gives no precipitate with nitrate of silver or chloride of barium" (*Br.*), indicating the absence of chlorides, carbonates, and sulphates.

Medical Uses. This salt has been praised as a remedy in dysentery by two German physicians, Drs. Velsen and Meyer, given in the quantity of from half an ounce to an ounce in the course of the day, dissolved in gum-water, or other mucilaginous liquid. It has been used with success in the same disease by Dr. Rademacher, of Vienna, who recommends it in a number of other diseases having nothing in common. (*Ann. de Thérap.*, 1854.) Dr. J. B. Brown also bears very emphatic testimony to the value of nitrate of soda as a speedy and safe remedy in dysentery and dysenteric diarrhœa. (*Charleston Med. Journ.*, May, 1854, p. 398; from *North-Western Med. and Surg. Journ.*)

SODÆ SULPHAS. *U. S., Br.*

Sulphate of Soda.

NaO,SO_3+10HO. *Br*

Vitriolated soda. Glauber's salt; Sulfate de soude, *Fr.;* Schwefelsaures Natron, Glaubersalz, *Germ.:* Solfato di soda, *Ital.;* Sulfato de soda, Sal de Glaubero, *Span.*

Sulphate of soda, in small quantities, is extensively diffused in nature, and is obtained artificially in several chemical operations. It exists in solution in

many mineral springs, among which may be mentioned those of Cheltenham and Carlsbad; and it is found combined with sulphate of lime, constituting a distinct mineral. Many ponds containing this salt are found in the country between Santa Fe and the head-waters of the Arkansas, and on the route to the Rocky Mountains. The water in one of these ponds forms a solution so highly concentrated that, in dry weather, the salt crystallizes on the surface to the depth of several inches, so as to have the appearance of limpid ice. (*Am. Journ. of Pharm.*, xii. 110.) As an artificial product, it is formed in the processes for obtaining muriatic acid and chlorine, and in the preparation of muriate of ammonia from sulphate of ammonia and common salt. It may also be procured from sea-water, in which its ingredients are present.

Immense quantities of sulphate of soda are made by decomposing common salt by sulphuric acid, in the manufacture of soda-ash and carbonate of soda; and, so far from the generated muriatic acid being a product of value, its absorption in a convenient way, so as to avoid the nuisance of its escape into the atmosphere in a gaseous state, is an object of importance to the manufacturer. (See *Acidum Muriaticum.*) MM. Thomas, Dellisse, and Boucard have proposed a new process for preparing sulphate of soda, by double decomposition between chloride of sodium and sulphate of iron. This process avoids the production of muriatic acid vapours, and is said to furnish a cheap salt.

The residue of the process for obtaining chlorine, by the action of sulphuric acid and deutoxide of manganese on common salt, is a mixture of sulphate of soda and sulphate of protoxide of manganese. (See *Chlorinii Liquor.*) Large quantities of this residue are formed in manufacturing chlorinated lime (bleaching salt); and the sulphate of soda in it, roughly purified, supplies a part of the consumption of this salt in making soda-ash and carbonate of soda.

The process for obtaining muriate of ammonia from sulphate of ammonia and common salt, forms another source of sulphate of soda. By double decomposition, sulphate of soda and muriate of ammonia are formed; and by exposing the mixed salts to heat, the muriate of ammonia sublimes, and the sulphate of soda remains behind. (See *Ammoniæ Murias.*)

In some of the Northern States, a portion of Glauber's salt is procured from sea-water in the winter. The circumstances under which it is formed have been explained by Mr. D. B. Smith, of this city. The constituents of several salts exist in sea-water, and the binary order in which these constituents will precipitate, upon evaporation, depends on the temperature. During the prevalence of rigorous cold, sulphate of soda is the least soluble salt which can be formed out of the acids and bases present, and consequently separates in the form of crystals.

Properties. Sulphate of soda is a colourless salt, possessing a cooling, nauseous, bitter taste, and crystallizing with great facility in six-sided striated prisms. When recently prepared, it is beautifully transparent; but by exposure to the air it effloresces, and the crystals become covered with an opaque white powder. By long exposure it undergoes complete efflorescence, and falls into powder with loss of more than half its weight. It is soluble in three times its weight of cold water, and in its own weight of boiling water, but is insoluble in alcohol. A supersaturated solution of sulphate of soda will remain without crystallizing at ordinary temperatures, even though containing several times the weight of the salt that will be dissolved at the same degree of heat. (*Gay-Lussac.*) But the solution instantly forms into a crystalline mass upon adding to it a fragment of the same salt crystallized, or other substances that have been exposed to the air, or upon abruptly placing it in contact with the air. M. D. Gernez appears to have proved that in each instance the cause of crystallization is the same, namely sulphate of soda containing 10 eqs. of water; and where the crystal itself is not added, the result is owing to sulphate of soda existing in the air. (See *Am. Journ. of Pharm.*, Sept. 1865, p. 379.) Subjected to heat, it dissolves in its water of crystallization, then dries, and afterwards, by the application of a red heat, melts, with the loss of 55½ per cent. of its weight. Occasionally it contains an excess of acid or alkali, which may

be discovered by litmus or turmeric paper. Common salt may be detected by sulphate of silver; that of iron by ferrocyanide of potassium or tincture of galls. This salt is not subject to adulteration. It is incompatible with carbonate of potassa, chloride of calcium, the salts of baryta, acetate and subacetate of lead, and with nitrate of silver if the solutions are strong. It consists of one eq. of sulphuric acid 40, one of soda 31·3, and ten of water 90 = 161·3.

Medical Properties and Uses. Sulphate of soda, in doses of from half an ounce to an ounce, is an efficient cathartic; in smaller doses, an aperient and diuretic. When in an effloresced state, the dose must be reduced one-half, on account of its having lost about one-half of its weight in water. Prof. Buckheim has ascertained, by experiment, that the ingestion of this salt causes an increase of sulphates in the urine, especially if its purgative action be delayed or prevented by other medicines. These results were not affected by the quantity of water taken with the salt. Sulphate of soda is much less used than formerly, having been almost entirely superseded by sulphate of magnesia, which is less disagreeable to take. Its nauseous taste, however, may be disguised by the admixture of a little lemon-juice or cream of tartar, or the addition of a few drops of sulphuric acid. It is an ingredient in the artificial Cheltenham salt. (See *Part* III.) A new application of sulphate of soda has recently been made by M. D. de Luca, of Naples, who has found it remarkably efficient in removing stains or opacity of the cornea, which he supposes it to do by its property of dissolving albumen, which in a coagulated state is the frequent cause of the opacity. He employed at first a cold saturated solution of the salt, but, not finding it to act with the desired rapidity, he substituted the powdered crystals, letting fall pinches of the powder on the globe of the eye; the head being placed horizontally. Under this treatment the stains of the cornea begin to disappear in a few days. The application may be made twice a day. The patient experiences an agreeable feeling of coolness, as the salt dissolves in the liquids of the eye. (*Journ. de Pharm. et de Chim.*, Sept. 1867, p. 188.) The only use of sulphate of soda in the arts is to make carbonate of soda, and as an ingredient in some kinds of glass. It has no officinal preparations. B.

SODÆ SULPHIS. *U. S.*

Sulphite of Soda.

This salt was first adopted as officinal in the present edition of the U. S. Pharmacopœia. It may be prepared by passing sulphurous acid into a solution of carbonate of soda, and evaporating out of contact of the air. The sulphurous acid unites with the soda of the carbonate, to form the sulphite of soda, and the carbonic acid escapes. After sufficient concentration, the solution is allowed to cool, and the salt crystallizes.

Properties. Sulphite of soda is in the form of white prismatic crystals, soluble in four parts of cold, and less than their weight of boiling water. Sulphuric acid added to the solution gives rise to a smell of burning sulphur, owing to the escape of sulphurous acid; and the liquid remains transparent, indicating the absence of lime. Sulphite of soda consists of one eq. of soda, one of sulphurous acid, and three of water ($NaO,SO_2 + 3HO$). The salt should be kept in bottles well stopped; as it gradually changes on exposure into sulphate of soda.

Medical Uses. Sulphite of soda has been used in cases of yeasty vomiting with remarkable success. The matter vomited in these cases has a yeasty appearance on the surface, and is generally found to contain, when examined by the microscope, two microscopic fungi, called sarcina ventriculi and torula cerevisiæ. The remedy was first used at the suggestion of Prof. Graham, of London, who supposed that the sulphurous acid, necessarily extricated from the salt in the stomach by the acid of the yeasty matter, would destroy the parasites. Dr. Dobie, of Edinburgh, has reported two cases of yeasty vomiting, occurring under his observation, in which the disease was immediately checked by the sulphite. In

one of the cases the vomited matter contained an enormous quantity of the torula, without sarcinæ. (*Ed. Monthly Journ.*, xiv. 574.) Dr. Astrié, an Italian physician, has proposed this salt as a remedy for the constitutional effects of mercury, when used in excess, on the ground that it has the power of rendering the metal soluble. The dose of sulphite of soda is a drachm three times a day.

Sulphite of soda is sometimes used locally, especially in that species of aphthous sore-mouth which is attributed to a parasitic vegetable. The wash may be made of a drachm of the salt to a fluidounce of water. The acid secretions of the mouth extricate the sulphurous acid, which kills the parasite. It is said that the solution acts with surprising rapidity, a single application of it sometimes removing the disease in 24 hours. From what has been said it is evident that sulphite of soda as a remedy is equivalent to sulphurous acid; since its employment, whether internally or externally, is always attended with the extrication of this acid. (See *Acidum Sulphurosum*, Part II.) B.

Since the experiments of Dr. Polli, referred to in *page* 823, sulphite of soda has been employed to a considerable extent internally in reference to its antizymotic properties; the supposition being that, as it suppresses fermentation out of the body, it may have a similar effect on analogous changes presumed to occur in the blood, and thus promote a cure. It is not necessary to adopt the theory of organized agents as essential to fermentation; so that the non-discovery of such agents in the blood by the microscope cannot be admitted as evidence against the mode of operation referred to, namely as an antizymotic action. Some experiments of Mr. M. Carey Lea tend to confirm this view. (*Am. Journ. of Med. Sci.*, Jan. 1865, p. 843.) Mr. Lea found that the sulphites, though to a considerable extent changed into sulphates, and appearing as such in the urine, yet, when taken in a certain amount and for a certain time, they in part pass unaltered, and are found as sulphites in the urine; proving incontestably that they must exist, at least to the same extent, in the blood, and may, therefore, exercise their antizymotic powers on that fluid. In a communication by Dr. W. F. Atlee (*Ibid.* p. 82), an account is given of two cases of purulent infection of a very serious character, both of which recovered under the use of the bisulphite of soda, in one of which 8 grains were given every two hours, in the other 20 grains as often; the bisulphite being understood to operate on the same principle as the sulphite; and both by the sulphurous acid they contain. Indeed, all the alkaline compounds of the sulphurous acids, including sulphites, bisulphites, and hyposulphites, may be considered therapeutically in the same category, all operating, as is supposed, whether generally or locally, through their antizymotic effects, with little other influence, in the doses ordinarily given, on the system or its functions, than that of the refrigerant salts. Indeed, as has been stated, they are in great measure converted into sulphates. In the choice of them, consequently, one is preferred to another from causes independent of their antizymotic character. While, therefore, in speaking of their therapeutical action, we may treat of them together, each one requires a distinct consideration as regards its sensible and physical properties, preparation, and mode of exhibition. In this way they are treated of severally in this work, each in a place corresponding with the alphabetical position and its recognition or non-recognition in the officinal catalogues. The diseases in which those medicines have been recommended are purulent infection of whatever origin, malignant pustule, hospital gangrene, erysipelas and other exanthematous fevers, malarial and miasmatic fevers, and in fine all diseases which may be supposed to depend on absorbed poisons not acting on the tissues, but by a species of fermentation. In the present state of our knowledge on this point, all conclusions not dependent on actual experience must be considered as purely speculative; and, while many cases may be adduced from the journals of highly favourable effects,* yet the op-

* A case of severe rattlesnake poisoning is reported by Dr. G. M. Staples, of Dubuque, Iowa, in which recovery took place under the use of bisulphite of soda, in doses of a scruple every half hour for four hours, then every hour for six hours, then every two

posing testimony is probably still stronger, and the tendency seems to be on the whole unfavourable. Thus, Semmola states, with much positiveness, that the results from the sulphites are completely negative in typhus, scarlatina, measles, marsh fevers, syphilis, malignant pustules, and purulent infection. (*Ann. de Thérap.*, 1865, p. 170.) With such conflicting sentiments the practitioner will be fully justified in deciding for himself whether to employ them; for there is this extraordinary fact which may be urged in their favour, that, if they do no good, they are not likely, in the doses ordinarily used, to do much harm.

Locally applied, there seems to be no doubt that the sulphites and other substances of this class are often very useful. Besides the application to the throat or sore-mouth of infants above mentioned, they have been found extremely useful in controlling suppurative ulcers, and all suppurative affections of the mucous membranes, as of the urinary passages, the bronchial tubes, and the alimentary canal, in which there is reason to think that the local affection is sustained by zymotic influence or invisible organisms, and in which purulent infection of the blood may be produced by the same cause. They appear almost to act as specifics in such cases. At a certain stage of cancer of the womb they operate usefully in the same way, by obviating the effects of putrid fermentations. For these various purposes the sulphite of soda may be used in solution in the proportion of one part of the salt to 10 of water, whenever it is to be used as a lotion, dressing for wounds, inhalation by the atomizer, &c. When it may be desirable to employ it as a cataplasm, it may be dissolved, in the same proportion or rather larger, in glycerin, and the solution thickened with powdered starch. W.

SODII CHLORIDUM. *U. S., Br.*

Chloride of Sodium. Common Salt.

Muriate of soda, Sea salt, Common salt; Chlorure de sodium, Hydro-chlorate de soude, Sel marin, *Fr.;* Chlornatrium, Kochsalz, *Germ.;* Salt, *Dan., Swed.;* Chloruro di sodio, Sal commune, *Ital.;* Sal, *Span.*

This mineral production, so necessary to mankind, is universally distributed over the globe, and is the most abundant of the native soluble salts. Most animals have an instinctive relish for it; and, from its frequent presence in the solids and fluids of the animal economy, it may be supposed to perform an important part in assimilation and nutrition.

Natural State. Common salt exists in nature, either in the solid state or in solution. In the solid state, called *rock salt, fossil salt,* and *sal gemmæ,* it is often found forming extensive beds, and even entire mountains, from which it is extracted in blocks or masses by mining operations. Its geological position is very constant, occurring almost invariably in secondary formations, associated with clay and gypsum. In solution it occurs in certain springs and lakes, and in the waters of the ocean. The principal salt mines are found in Poland, Hungary, and Russia; in various parts of Germany, particularly the Tyrol; in Cheshire, England; in Spain; in various parts of Asia and Africa; in the island of St. Domingo;* and in Peru, and other countries of South America. With the exception of a remarkable bed of rock salt in the island of Petite Anse, in Vermillion Bay, on the coast of Louisiana, there are in the United States no salt mines east of the Rocky Mountains; but there are numerous salt

hours for twelve hours, and lastly every four hours. Other remedies were employed at the same time; and it is impossible to determine how much of the result was ascribable to the bisulphite. At all events, the experience in this case was sufficiently encouraging to justify the use of the same remedy in similar cases hereafter. (*Med. and Surg. Reporter*, Oct. 28, 1865, p. 279.)—*Note to the thirteenth edition.*

* This deposit is on the south side of the island, and is said to form a mountain 6 miles long, from half a mile to a mile broad, and from 400 to 500 feet high. The salt in its crude state contains 96·79 per cent. of pure chloride of sodium. (*Am. Journ. of Pharm.*, Sept. 1865, p. 395; from *Am. Druggists' Circular.*)—*Note to the thirteenth edition*

springs, which either flow naturally, or are produced artificially by sinking wells to various depths in places where salt is known to exist.* These are found principally in Missouri, Kentucky, Illinois, Ohio, Michigan, Pennsylvania, Virginia, and New York. In the last-mentioned State the springs are the most productive; the chief ones being situated at Salina, Montezuma, and Galen. In Virginia an important salt region exists, extending fifteen miles on both sides of the Great Kanawha river. Rock salt is always transparent or translucent; but it often exhibits various colours, such as red, yellow, brown, violet, blue, &c., which are supposed to be derived from iron and manganese.

Extraction. Mines of salt are worked in two ways. When the salt is pure it is merely dug out in blocks and thrown into commerce. When impure it is dissolved in water, and extracted afterwards from the solution by evaporation When the salt is naturally in solution, the mode of extraction depends upon the strength of the brine, and the temperature of the place where it is found. When the water contains from 14 to 15 per cent. of the salt, it is extracted by evaporation in large iron boilers. If, however, it contains only 2, 3, 4, or 5 per cent., the salt is obtained in a different manner. If the climate is warm it is procured by spontaneous evaporation, effected by the heat of the sun; if temperate, by a peculiar mode of evaporation to be mentioned presently, and the subsequent application of artificial heat.

Sea-water is a weak saline solution, containing 2·7 per cent. of common salt, which is extracted by the agency of solar heat in warm countries. Salt thus obtained is called *bay salt.* The extraction is conducted in Europe principally on the shores of the Mediterranean, the waters of which are salter than those of the open ocean. The mode in which it is performed is by letting the sea-water into shallow dikes, lined with clay, and capable, after having been filled, of being shut off from the sea. In this situation the heat of the sun gradually concentrates the water, and the salt is deposited. In temperate climates, weak brines are first concentrated in buildings called *graduation houses.* These are rough wooden structures open on the sides, ten or eleven yards high, five or six wide, and three or four hundred long, and containing an oblong pile of brushwood somewhat smaller than the building itself. The brine is pumped up into troughs full of holes, placed above the brushwood, upon which it is allowed to fall; and in its descent becomes minutely divided. This operation, by greatly increasing the surface of the brine, promotes its evaporation; and, being repeated several times, the solution is at last brought to the requisite degree of strength to permit of its final concentration in iron boilers by artificial heat.

Properties. Chloride of sodium is white, without odour, and of a peculiar taste called saline. It is usually crystallized in cubes; but by hasty evaporation it often assumes the form of hollow quadrangular pyramids. When pure it undergoes no change in the air; but, when contaminated with chloride of magnesium, as not unfrequently happens, it is deliquescent. Water at 54° F dissolves 36 per cent. of this salt, and at the boiling temperature, 40 per cent. (*Fehling.*) It is but sparingly soluble in alcohol. One hundred parts of this liquid (sp. gr. 0·815) dissolve, at the temperature of 59°, only 0·174 parts of common salt. (*R. Wagner.*) Exposed to a gradually increasing heat, it first decrepitates from the presence of interstitial moisture, next melts, and finally volatilizes in white fumes with but partial decomposition. (Mulder, *Journ. de Pharm. et de Chim.*, 4e éd., iii. 390.) It is decomposed by several of the acids, particularly the sulphuric and nitric, which disengage vapours of muriatic acid; by carbonate of potassa with the assistance of heat; and by the nitrates of silver and protoxide of mercury.

Several varieties of common salt are distinguished in commerce; as *stoved*

* *Rock salt in Nevada.* In an extract from a letter, dated at Virginia City, in the new State of Nevada, adjoining California, published in one of our daily papers (*North American and United States Gaz.*, Nov. 2, 1864), it is said that, near Carson River, in that State, a basin of common salt had been discovered, five miles square in extent, and fourteen feet in thickness. The salt is said to be very pure, hard, and as clear as crystal, and capable of being mined with great facility. (*Note to the twelfth edition.*)

salt, fishery salt, bay salt, &c.; but they are characterized by the size and compactness of the grains, rather than by any difference in composition.

Composition. Common salt, in its pure state, consists of one eq. of chlorine 35·5, and one of sodium 23·3 = 58·8. It contains no water of crystallization. When in solution it is by some supposed to become muriate of soda, in consequence of the decomposition of water, the hydrogen and oxygen of which are alleged to convert the chlorine and sodium into muriatic acid and soda. The common salt of commerce, besides pure chloride of sodium, contains, generally speaking, insoluble matter, and usually more or less of the sulphates of lime and magnesia, and chlorides of calcium and magnesium. When pure it is not precipitated by carbonate of soda, chloride of barium, or ferrocyanide of potassium. Chloride of calcium is generally present in very small amount; but the chloride of magnesium sometimes amounts to 28 parts in 1000. Sulphate of lime is usually present; constituting variously from 1 to 23½ parts in 1000; and sulphate of magnesia is sometimes present and sometimes absent. To separate the earths, a boiling solution of carbonate of soda must be added, as long as any precipitate is formed. The earths will fall as carbonates, and must be separated by filtration, and the sulphate of soda and chloride of sodium, resulting from the double decomposition, will remain in solution. The sulphate of soda may then be decomposed by the cautious addition of chloride of barium, which will generate chloride of sodium and insoluble sulphate of baryta.

Medical Properties, &c. Chloride of sodium, in small doses, acts as a stimulant tonic and anthelmintic; in larger ones as a purgative and emetic. It certainly promotes digestion, and the almost universal animal appetency for it proves it to be a salutary stimulus in health. From the experiments of Prof. Buckheim, it appears that common salt quickly passes into the blood, and is thrown off in greater part, in six hours, by the kidneys. The portion not found in the urine and fæces is probably appropriated to the uses of the economy. According to the experiments of M. Plouviez, made upon himself, at intervals, during twenty-five months, a saline regimen has the effect of increasing the weight and strength of the body. He began with a teaspoonful daily, which he increased to a tablespoonful, continuing to take this dose for a period of three or four months. The regimen appeared to produce plethora. The blood, analyzed while under the full effects of the salt, was found to contain more of the corpuscles and salts, but less of the albumen and water.

Common salt has been used with good effect by a number of practitioners as a remedy in intermittent fever. This practice is said to have been long followed in Hungary. In 1850 it was brought to the notice of the profession by M. Scelle-Mondezert, of Charenton, on whose results M. Piorry reported favourably. Since then the power of common salt as an antiperiodic has been attested by Dr. Lattimore of New York, Dr. Hutchinson of Brooklyn, Dr. Moroschkin of Russia, and others. In some cases, observed by M. Piorry, the spleen rapidly diminished in size. It is not alleged to be equal to quinia; but, while it cures many cases, it has the merit of cheapness. The dose is from eight to twelve drachms, given in divided doses during the apyrexia. It is best administered in mucilage of slippery elm, or in coffee.

On the sudden occurrence of hæmoptysis, common salt is usefully resorted to as a styptic, in the dose of a teaspoonful, taken dry, and often proves successful in stopping the flow of blood. Externally applied in solution it is stimulant, and may be used either locally or generally. Locally, it is sometimes employed as a fomentation in sprains and bruises; and as a general external application it forms the salt-water bath, a valuable remedy as a tonic and excitant in depraved conditions of the system, especially when occurring in children. A pound of salt, dissolved in four gallons of water, forms a solution of about the strength of sea-water, and suitable for a bath. The dose, as a tonic, is from ten grains to a drachm; as a cathartic, from two drachms to half an ounce. In doses of from half an ounce to an ounce, dissolved in four or five times its weight of water, it frequently proves a prompt and efficient emetic, invigorating rather

than depressing the powers of the system. It is frequently used as a clyster, in the quantity of from one to two tablespoonfuls in a pint of water.

The uses of common salt in domestic economy as a condiment and antiseptic are well known. In pharmacy it is employed to prepare chlorine, muriatic acid, muriate of ammonia, calomel, and corrosive sublimate. It is also used to form sulphate of soda, with a view to its conversion into carbonate of soda.

Off. Prep. Acidum Hydrochloricum, *Br.;* Hydrargyri Chloridum Corrosivum, *U. S.;* Hydrargyri Chloridum Mite, *U. S.;* Hydrargyri Perchloridum, *Br.;* Hydrargyri Subchloridum, *Br.* B.

SOLIDAGO. *U. S. Secondary.*

Golden-rod.

The leaves of Solidago odora. *U. S.*

Solidago. *Sex. Syst.* Syngenesia Superflua. — *Nat. Ord.* Compositæ Asteroideæ, *De Candolle;* Asteraceæ, *Lindley.*

Gen. Ch. Calyx imbricated, scales closed. *Radical florets* about five, yellow. *Receptacle* naked, punctate. *Pappus* simple, pilose. *Nuttall.*

This is a very abundant genus, including, according to Eaton's enumeration, upwards of sixty species belonging to this country. Of these *S. odora* only is officinal. *S. Virgaurea*, which is common to the United States and Europe, was formerly directed by the Dublin College. It is astringent, and has been supposed to possess lithontriptic virtues.

Solidago odora. Willd. *Sp. Plant.* iii. 2061; Bigelow, *Am. Med. Bot.* i. 187. *Sweet-scented golden-rod* has a perennial creeping root, and a slender, erect, pubescent stem, two or three feet high. The leaves are sessile, linear-lanceolate, entire, acute, rough at the margin, elsewhere smooth, and covered with pellucid dots. The flowers are of a deep golden-yellow colour, and are arranged in a terminal, compound, panicled raceme, the branches of which spread almost horizontally, are each accompanied by a small leaf, and support the flowers on downy pedicels, which put forth from the upper side of the peduncle, and have small linear bractes at their base. The florets of the ray are ligulate, oblong, and obtuse; those of the disk, funnel-shaped, with acute segments.

The plant grows in woods and fields throughout the United States, and is in flower from August to October. The leaves, which are the officinal portion, have a fragrant odour, and a warm, aromatic, agreeable taste. These properties depend on a volatile oil, which may be separated by distillation with water. It is of a pale greenish-yellow colour, and lighter than water.

Medical Properties and Uses. Golden-rod is aromatic, moderately stimulant and carminative, and, like other substances of the same class, diaphoretic when given in warm infusion. It may be used to relieve pain arising from flatulence, to allay nausea, and to cover the taste or correct the operation of unpleasant or irritating medicines. For these purposes it may be given in infusion. The volatile oil dissolved in alcohol is employed in the Eastern States. According to Pursh, the dried flowers are used as a pleasant and wholesome substitute for common tea. W.

SPIGELIA. *U. S.*

Spigelia. Pinkroot.

The root of Spigelia Marilandica. *U. S.*

Spigélie du Maryland, *Fr.;* Spigelie, *Germ.;* Spigelia, *Ital.*

Spigelia. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Gentianaceæ, *Juss.;* Spigeliaceæ, *Martius, Lindley.*

Gen. Ch. Calyx five-parted. *Corolla* funnel-shaped, border five-cleft, equal. *Capsule* didymous, two-celled, four-valved, many-seeded. *Nuttall.*

Two species of Spigelia have attracted attention as anthelmintics, *S. anthelmia* of South America and the West Indies, and *S. Marilandica* of this country.

The former is an annual plant, used only in the countries where it grows; the latter is much employed both in this country and in Europe.

Spigelia Marilandica. Willd. *Sp. Plant.* i. 825; Bigelow, *Am. Med. Bot.* i. 142; Barton, *Med. Bot.* ii. 75. The *Carolina pink* is an herbaceous plant with a perennial root, which sends off numerous fibrous branches. The stems, several of which rise from the same root, are simple, erect, four-sided, nearly smooth, and from twelve to twenty inches high. The leaves are opposite, sessile, ovate-lanceolate, acuminate, entire, and smooth, with the veins and margins slightly pubescent. Each stem terminates in a spike, which leans to one side, and supports from four to twelve flowers with very short peduncles. The calyx is persistent, with five long, subulate, slightly serrate leaves, reflexed in the ripe fruit. The corolla is funnel-shaped, and much longer than the calyx, with the tube inflated in the middle, and the border divided into five acute, spreading segments. It is of a rich carmine colour externally, paler at the base, and orange-yellow within. The edges of the segments are slightly tinged with green. The stamens, though apparently very short, and inserted into the upper part of the tube between the segments, may be traced down its internal surface to the base. The anthers are oblong, heart-shaped; the germ superior, ovate; the style about the length of the corolla, and terminating in a linear fringed stigma, projecting considerably beyond it. The capsule is double, consisting of two cohering, globular, one-celled portions with many seeds.

The plant is a native of our Southern and Southwestern States, being seldom found north of the Potomac. It grows in rich soils on the borders of woods, and flowers from May to July. The root is the only part recognised in the Pharmacopœias. The drug was formerly collected in Georgia and the neighbouring States by the Creek and Cherokee Indians, who disposed of it to the white traders. The whole plant was gathered and dried, and came to us in bales or casks. After the emigration of the Indians, the supply of spigelia from this source very much diminished, and has now nearly if not quite failed. The consequence was for a time a great scarcity, and increase in the price of the drug; but a new source of supply was opened from the Western and Southwestern States, and it is now again plentiful. As we receive spigelia at present, it consists chiefly if not exclusively of the root, without the stem and leaves. We have been informed that most of it comes in casks or bales from St. Louis by the way of New Orleans. That contained in casks is to be preferred, as less liable to be damp and mouldy.

Properties. Pinkroot consists of numerous slender, branching, crooked, wrinkled fibres, from three to six inches long, attached to a knotty head or caudex, which exhibits traces of the stems of former years. It is brownish or yellowish-brown externally, of a faint, peculiar smell, and a sweetish, slightly bitter, not very disagreeable taste. Its virtues are extracted by boiling water. The root, analyzed by M. Feneulle, yielded a fixed and volatile oil, a small quantity of resin, a bitter substance supposed to be the active principle, a mucilaginous saccharine matter, albumen, gallic acid, the malates of potassa and lime, &c., and woody fibre. The principle upon which the virtues of the root are thought to depend is brown, of a bitter nauseous taste, like that of the purgative matter of the leguminous plants, and, when taken internally, produces vertigo and a kind of intoxication. An analysis of the root by Dr. R. H. Stabler yielded as results, a bitter uncrystallizable principle upon which the virtues of the medicine are supposed to depend, a little volatile oil, tannic acid, inert extractive, wax, resin, lignin, and salts of soda, potassa, and lime. The active principle is acrid and bitter, soluble in water and alcohol, insoluble in ether, not volatilizable without change, uncrystallizable, neuter, and deliquescent. It was obtained by treating a decoction of the root with subacetate of lead in excess, filtering, precipitating the lead by sulphuric acid, again filtering, evaporating by means of a steam bath to a soft extract, treating this with alcohol, filtering the alcoholic solution, decolorizing with animal charcoal, and evaporating by steam as before. The residue yielded nothing to ether, and was of a reddish-brown colour. (*Proceed. of the Am. Pharm. Assoc.*, A. D. 1857.)

The stalks of the dried plant are oval below the first pair of leaves, and then become obscurely four-sided. The leaves, when good, have a fresh greenish colour, and an odour somewhat like that of tea. In taste they resemble the root, and afforded to M. Feneulle nearly the same principles. The quantity, however, of the bitter substance was less, corresponding with their inferior efficacy. This circumstance should cause their rejection from the shops; as the inequality in power of the two portions of the plant would lead to uncertainty in the result, when they are both employed.

The roots are sometimes mixed with those of other plants, particularly of a small vine which twines round the stem of the Spigelia. These are long, slender, crooked, yellowish, thickly set with short capillary fibres, and much smaller and lighter-coloured than the pinkroot. They should be separated before the latter is used. The activity of spigelia is somewhat diminished by time.

Medical Properties and Uses. Pinkroot is generally considered among the most powerful anthelmintics. In the ordinary dose it usually produces little sensible effect on the system; more largely given it acts as a cathartic, though unequal and uncertain in its operation; in overdoses it excites the circulation, and determines to the brain, giving rise to vertigo, dimness of vision, dilated pupils, spasms of the facial muscles, and sometimes even to general convulsions. Spasmodic movements of the eyelids have been observed among the most common attendants of its narcotic action. The death of two children, who expired in convulsions, was attributed by Dr. Chalmers to the influence of spigelia. The narcotic effects are said to be less apt to occur when the medicine purges, and to be altogether obviated by combining it with cathartics. The danger from its employment cannot be great; as it is in very general use in the United States, both in regular and domestic practice, and we never hear at present of serious consequences. Its effects upon the nervous system have been erroneously conjectured to depend on other roots sometimes mixed with the genuine. The vermifuge properties of spigelia were first learned from the Cherokee Indians. They were made known to the medical profession by Drs. Lining, Garden, and Chalmers, of South Carolina. The remedy has also been recommended in infantile remittents and other febrile diseases; but is entitled to little confidence in these complaints.

It may be given in substance or infusion. The dose of the powdered root, for a child three or four years old, is from ten to twenty grains, for an adult from one to two drachms, to be repeated morning and evening for several days successively, and then followed by a brisk cathartic. The practice of preceding its use by an emetic has been generally abandoned. It is frequently given in combination with calomel. The infusion, however, is a more common form of administration. (See *Infusum Spigeliæ.*) It is usually combined with senna or some other cathartic, to ensure its action on the bowels. A preparation generally kept in the shops, and much prescribed by physicians, under the name of *worm tea*, consists of pinkroot, senna, manna, and savine, mixed together, in various proportions, to suit the views of different individuals. Spigelia is also very often given in the form of fluid extract.

Off. Prep. Extract. Spigeliæ Fluidum, *U. S.;* Infusum Spigeliæ, *U. S.* W.

SPIRÆA. *U. S. Secondary.*

Hardhack.

The root of Spiræa tomentosa. *U. S.*

Spiræa. *Sex. Syst.* Icosandria Pentagynia. — *Nat. Ord.* Rosaceæ.

Gen. Ch. Calyx spreading, five-cleft, inferior. *Petals* five, equal, roundish. *Stamens* numerous, exserted. *Capsules* three to twelve, internally bivalve, each one to three-seeded. *Nuttall.*

Spiræa ulmaria, queen of the meadow, or *meadow-sweet,* which is a European plant, though introduced into this country, has been found by M. Tessier,

of Lyons, to possess valuable diuretic properties, united with those of a moderate tonic and astringent. All parts of it are active. M. Tessier employed it in the form of decoction, of which he gave a quart daily. For more extended observations in relation to this medicine, see Bouchardat's *Annuaire de Thérapeutique* (A. D. 1852, p. 119).

Spiræa tomentosa. Willd. *Sp. Plant.* ii. 1056; Rafinesque, *Med. Flor.* vol. ii. This is an indigenous shrub, two or three feet high, with numerous simple, erect, round, downy, and purplish stems, furnished with alternate leaves, closely set upon very short footstalks. The leaves are ovate-lanceolate, unequally serrate, somewhat pointed at both ends, dark-green on their upper surface, whitish and tomentose beneath. The flowers are beautifully red or purple, and disposed in terminal, compound, crowded spikes or racemes.

The hardhack flourishes in low grounds, from New England to Carolina, but is most abundant in the Northern States. It flowers in July and August. All parts of it are medicinal. The root, though designated in the Pharmacopœia, is, according to Dr. A. W. Ives, the least valuable portion. The taste of the plant is bitter and strongly astringent. Among its constituents are tannin, gallic acid, and bitter extractive. Water extracts its medicinal virtues.

Medical Properties and Uses. Spiræa is tonic and astringent, and may be used in diarrhœa, cholera infantum, and other complaints in which astringents are indicated. In consequence of its tonic powers it is peculiarly adapted to cases of debility; and, from the same cause, should not be given during the existence of inflammatory action, or febrile excitement. It is said to have been employed by the aborigines; but was first brought to the notice of the medical profession by Dr. Cogswell, of Hartford, Connecticut. It is said to be less apt to disagree with the stomach than most other astringents.

The form in which it is best administered is that of an extract, prepared by evaporating the decoction of the leaves, stems, or root, or an infusion of the same parts made by percolation. The dose is from five to fifteen grains, repeated several times a day. A decoction, prepared by boiling an ounce of the plant in a pint of water, may be given in the dose of one or two fluidounces.

W.

SPIRITUS FRUMENTI. *U. S.*

Whisky.

Spirit obtained from fermented grain by distillation, and containing from 48 to 56 per cent. of absolute alcohol. For medicinal use, it should be free from disagreeable odour, and not less than two years old. *U. S.*

The term *whisky* is said to have been first applied to the spirit obtained from barley, in the Highlands of Scotland, and to signify water in the language of the people of that region. (*Rees's Cyclopædia.*) In the strict sense of the word, as at present understood, and as officinally defined, it belongs to the distilled spirit from different grains, including wheat, rye, barley, and Indian corn. We have been informed that the famous Bourbon whisky, from Kentucky, is prepared from Indian corn, previously malted and kiln dried. The common whisky of this country is generally made from rye. The term, however, is sometimes extended to other forms of ardent spirit; and that resulting from the distillation of cider is frequently designated as *apple whisky.*

In the preparation of whisky, the infusion of rye or other grain is first made to undergo fermentation, by which the saccharine matter and indirectly the starch are converted into alcohol. In this state the liquid is called the *wash* This is submitted to distillation, and the product is denominated *low wines.* By a second distillation it becomes purer and stronger, and now takes the name of raw corn spirit or whisky. Sometimes, we are informed, it is submitted to a third distillation, in order still further to purify it. By time certain chemical changes take place by which the natural impurities contained in the liquor are destroyed, and the whisky becomes mellowed, losing the disagreeable odour and taste which it is apt to have when first distilled.

There are volatile principles naturally existing in the grains, which accompany the liquor in all its changes, and give their characteristic flavour to the resulting spirit. These can scarcely be considered as impurities. But there are others produced during the process of fermentation which serve seriously to contaminate the product. Among these is *fusel oil* or *grain oil* (amylic alcohol), which is offensive both to the smell and taste, and of which it is very desirable that the spirit should be freed as far as possible. As this oil has a considerably higher boiling point than alcohol or even water, it is mainly left behind, if the distillation be not carried too far; yet portions still rise, and to a certain extent impregnate the spirit. Minute proportions of acetic and butyric acids are often present in whisky, and valerianic acid has been detected. (*Am. Journ. of Pharm.*, Nov. 1859, p. 573.) According to Dr. A. A. Hayes, of Boston, all new spirits, prepared with copper stills, are liable to be adulterated with that metal, which, however, is, he thinks, deposited in the process of ripening which they undergo by time. (*Am. Journ. of Sci. and Arts*, July, 1861.)

Whisky, when recently prepared, is nearly colourless; but, when kept in casks, it gradually acquires a brownish colour, which deepens with time; and hence it may be found of various shades, from a slight yellowish-brown tint to the dark brown of brandy. Its taste and smell, when mellow by age, though peculiar, are not disagreeable. As directed by the Pharmacopœia it should contain from 48 to 56 per cent. of absolute alcohol, and its sp. gr. therefore should not exceed 0·922 at 60° F., nor be less than 0·904.*

It was introduced into the Pharmacopœia as a cheap substitute for brandy, and may be employed for all the purposes which that spirit is capable of fulfilling. Indeed, when of good quality, which can always be commanded, it is probably preferable as a medicinal agent to brandy such as is now generally sold in our markets. W.

SPIRITUS MYRCIÆ. *U. S.*

Spirit of Myrcia. Bay-rum.

The spirit obtained by distilling rum with the leaves of Myrcia acris. *U. S.*

This is a new officinal of the U. S. Pharmacopœia. It has been long in use as a most agreeable and refreshing perfume; and many persons, misled by the name, believed it to be prepared by distilling spirit from the leaves of the bay-tree (Laurus nobilis). It appears, however, from a paper published by Mr. John M. Maisch in the *American Journal of Pharmacy* for July, 1861, that this was an error. A leaf having been presented to him, brought from the West Indies, with the information that it was from the tree of which the leaves were used in preparing this spirit, he observed that it had precisely the characteristic odour and taste of bay-rum, and on comparing it with the leaves of a twig in the collection of the Academy of Natural Sciences of this city, brought by the late Dr. Griffiths from Saint Croix, and labeled as the plant from which bay-rum was prepared, found that the two closely corresponded. From the characters of the leaf, Prof. Bridges suggested that it might belong to a plant of the family Myrtaceæ, and most probably the Myrcia acris of De Candolle. Further investigation satisfied Mr. Maisch of the correctness of this reference; and there is little room to doubt that the source of this very agreeable perfume is really the plant indicated in the Pharmacopœia.

Myrcia. *Sex. Syst.* Icosandria Monogynia. — *Nat. Ord.* Myrtaceæ.

Gen. Ch. Calyx five-parted, tube subglobose. *Petals* five. *Stamens* numer-

* As quantity is strictly represented by weight, all statements of proportionate quantities should be so considered unless proportion by measure is expressly indicated. The Pharmacopœia in directing the percentage of alcohol in whisky does not give measure as its basis of proportion, and must, therefore, be considered as meaning by weight; and hence the specific gravities given in the text. If the percentage is to be estimated by measure, the sp. gr. of the 48 per cent. alcohol is, according to Tralle's Tables, 0·9373, and that of 56 per cent. 0·9213; and in this sense considerably weaker spirit would be admitted as officinal. (*Note to the thirteenth edition.*)

ous, free. *Ovary* two or three-celled. *Berry* one or two-celled, one to three-seeded. *Seed* subglobose, smooth; cotyledons foliaceous.

Myrcia acris. Schwartz; De Cand. *Prodrom.* v. 243; Curtis's *Bot. Mag.*, 2d ser., vol. vi. pl. 3153.—*Myrtus acris.* Willd. *Sp. Plant.* p. 973. The *bayberry*, as it is sometimes called, is a tree of considerable size, with a straight stem, and a thick pyramidal summit. The young branches are green and sharply four-angled. The leaves are opposite, from 3 to 5 inches long, very coriaceous, lanceolate, obtuse, wavy, somewhat revolute at the edges, with numerous parallel nerves, reticulated on the upper surface, and sprinkled with pellucid dots. They have a very fragrant odour, and are somewhat astringent. The flowers, which are arranged in pedunculate, axillary panicles, longer than the leaves, are small, and white with a reddish tinge. The berries are round, about as large as a pea, with 7 or 8 seeds, and of an aromatic smell and taste.

The tree is a native of Jamaica and other West India islands. The spirit is probably prepared by distilling rum from the leaves; but we are in want of precise information on the subject, and it is not impossible that the leaves of other species may also be used. Indeed an odour of pimento which it appears to us may be sometimes detected, suggests the idea that the leaves of this tree may be at least occasionally added to those of the bayberry. A *volatile oil* is also obtained from the leaves by distillation. This is described by Mr. Maisch in the same number of the *American Journal of Pharmacy* (p. 296). It is brownish-yellow, limpid, of an aromatic odour resembling that of allspice, and a warm spicy taste. It is lighter than water, readily soluble in ether, from which alcohol precipitates it, and partially soluble in alcohol. Its alcoholic solution has a feeble acid reaction.

Bay-rum is used chiefly as a refreshing perfume in cases of nervous headache, faintness, and other nervous disorders, either held to the nostrils or applied on soft linen to the head and forehead. It is also grateful to the feeble and convalescent patient, by being sprinkled on the bed covering, or otherwise made to impregnate the air of the chamber. W.

SPIRITUS VINI GALLICI. *U.S., Br.*

Brandy.

The spirit obtained from fermented grapes by distillation, and containing from 48 to 56 per cent. of absolute alcohol. Brandy, for medicinal use, should be free from disagreeable odour, and not less than four years old. *U. S. Spirit of French Wine.* Spirit distilled from French wine. It has a peculiar flavour, and a light sherry colour derived from the cask in which it has been kept. *Br.*

Eau de vie, *Fr.;* Branntwein, *Germ.;* Acquavite, *Ital.;* Agua ardiente, *Span.*

All liquids which have undergone the alcoholic fermentation yield an ardent spirit by distillation. (See *Alcohol*, page 77.) When the alcoholic liquid is wine, the product of the distillation is brandy. This ardent spirit is subject to variation, according to the character of the wine from which it is distilled. The best brandy is obtained from French wines, and the kinds called Cognac and Armagnac are most esteemed. The *catawba brandy* of Messrs. Longworth and Zimmermann, of Cincinnati, distilled from the lees of the catawba wine of Ohio, is a good brandy; but possesses the peculiar flavour of the wine. When the brandy is distilled from the marc of the catawba grape, it has an unpleasant taste, and contains a large amount of fusel oil. (E. S. Wayne, *Am. Journ. of Pharm.*, Nov. 1855, p. 498.) Our Pharmacopœia formerly recognised French brandy exclusively; but in the present edition all spirits are admitted under that name, when obtained from the juice of grapes, and sufficiently strong and pure to meet the requisitions above given. Of course the brandy from catawba grape, if well prepared, is now officinal.

Brandy has an agreeable, vinous, aromatic odour, and a peculiar, well-known taste. Its sp. gr. varies from 0·902 to 0·941, and it contains on an average 53

per cent. by measure of alcohol of the density 0·825. Besides alcohol, water, and volatile oil, it contains colouring matter, tannin, œnanthic ether described under *wine*, a little acetic ether, and a little aldehyd. Brandy is distinguished by its colour into the pale and high-coloured. *Pale brandy* has a yellow colour, derived from the cask in which it is kept. *High-coloured* brandy has a deep-red colour, given to it, before importation, by burnt sugar (caramel), which is said to impart a more agreeable flavour. *Factitious brandy* is sometimes made from alcohol, deprived of fusel oil, and reduced to the proper proof by water, by adding to it acetic ether in the proportion of from half an ounce to an ounce to the gallon. The proper colour is then given by burnt sugar. The spurious liquid may be known by its leaving on evaporation a residue, containing sugar and no tannin; the absence of the latter being shown by its not striking a black colour with the salts of sesquioxide of iron. It may also be detected by the absence of aldehyd. (*Magnes Lahens.*) For modes of detecting impurities in brandy and other forms of ardent spirit, the reader is referred to an article by Mr. S. P. Duffield, of Detroit, in the *Am. Journ. of Pharm.* for March, 1862 (p. 118).

Medical Properties. Brandy is esteemed cordial and stomachic, and is frequently given, in the form of toddy or milk-punch, in the sinking stages of low fevers. In the late Lond. Pharmacopœia there was an officinal preparation of it, called *Mistura Spiritus Vini Gallici*, consisting of brandy, cinnamon water, the yelks of eggs, sugar, and oil of cinnamon. This, though a convenient form for the administration of brandy, was omitted in the Br. Pharmacopœia. It has, however, been admitted into the new edition, and is now again officinal; but the oil has been omitted. If prepared with the U. S. cinnamon water, it would certainly be sufficiently flavoured without the addition of the oil. Brandy is in general most conveniently exhibited, in low fevers, mixed with milk, and flavoured with sugar; the proportions being varied to meet the demands of the case.

Off. Prep. Mistura Spiritus Vini Gallici, *Br.* B

STATICE. *U. S.*

Marsh Rosemary.

The root of Statice Limonium, variety Caroliniana. *U. S.*

Statice. *Sex. Syst.* Pentandria Pentagynia.—*Nat. Ord.* Plumbaginaceæ. *Gen. Ch. Calyx* one-leaved, entire, plaited, scariose. *Petals* five. *Seed* one, superior. *Nuttall.*

Statice Caroliniana. Walter, *Flor. Car.* 118; Bigelow, *Am. Med. Bot.* ii. 51. This is considered by Nuttall, Torrey, and some other botanists, as a mere variety of the *Statice Limonium* of Europe. Pursh, Bigelow, and others follow Walter in considering it as a distinct species. It is an indigenous maritime plant with a perennial root, sending up annually tufts of leaves, which are obovate or cuneiform, entire, obtuse, mucronate, smooth, and on long footstalks. They differ from the leaves of *S. Limonium* in being perfectly flat on the margin, while the latter are undulated. The flower-stem is round, smooth, from a few inches to a foot or more in height, sending off near its summit numerous alternate subdividing branches, which terminate in spikes, and form altogether a loose panicle. The flowers are small, bluish-purple, erect, upon one side only of the common peduncle, with a mucronate scaly bracte at the base of each, a five-angled, five-toothed calyx, and spatulate, obtuse petals.

Marsh rosemary grows in the salt marshes along the sea-coast, from New England to Florida, and flowers in August and September. The root, which is the officinal portion, is large, spindle-shaped or branched, fleshy, compact, rough, and of a purplish-brown colour. It is bitter and extremely astringent to the taste, but without odour. Mr. Edward Parrish, of Philadelphia, found it to contain tannic acid, gum, extractive, albumen, volatile oil, resin, caoutchouc, colouring matter, lignin, and various salts, among which were common salt, and the sulphates of soda and magnesia. The proportion of tannic acid was 12·4 per cent. (*Am. Journ. of Pharm.*, xiv. 116.)

Medical Properties and Uses. Statice is powerfully astringent, and in some parts of the United States, particularly in New England, is much employed. It may be used for all the purposes for which kino and catechu are given; but its chief popular application is to aphthous and ulcerative affections of the mouth and fauces. Dr. Baylies, of Massachusetts, found it highly useful in cynanche maligna, both as an internal and local remedy. It is employed in the form of infusion or decoction. W.

STILLINGIA. *U. S.*

Stillingia. Queen's-root.

The root of Stillingia sylvatica. *U. S.*

Stillingia. *Sex. Syst.* Monœcia Monadelphia. — *Nat. Ord.* Euphorbiaceæ. *Gen. Ch.* Male. *Involucre* hemispherical, many-flowered, or wanting. *Calyx* tubular, eroded. *Stamens* two and three, exserted. Female. *Calyx* one-flowered, inferior. *Style* trifid. *Capsule* three-grained. *Nuttall.*

From the fruit of *Stillingia sebifera*, the Chinese procure a *vegetable tallow* in large quantities, which is said to be almost pure stearin, and is much used in making candles. It exists between the shell of the seeds and the outer husk; the kernel, contained within the shell, yielding a liquid oil by expression. (*Pharm. Journ.*, xii. 73.)

Stillingia sylvatica. Willd. *Sp. Plant.* iv. 588. This is an indigenous perennial plant, commonly called *Queen's delight*, with herbaceous stems, two or three feet high, and alternate, sessile, oblong or lanceolate-oblong, obtuse, serrulate leaves, tapering at the base, and accompanied with stipules. The male and female flowers are distinct upon the same plant. They are yellow, and arranged in the form of a spike, of which the upper part is occupied by the male, the lower by the female flowers. The male florets are scarcely longer than the bracteal scales. The plant grows in pine-barrens from Virginia to Florida, flowering in May and June. When wounded it emits a milky juice.

The root, which is the part used, is large, thick, and woody. A specimen presented to the writer by Dr. J. B. Holmes, of Charleston, S. C., is in long cylindrical pieces, from a third of an inch to more than an inch thick, wrinkled from drying, of a dirty yellowish-brown colour externally, and, when cut across, exhibiting an interior soft, yellowish, ligneous portion, surrounded by a pinkish-coloured bark. The odour is slight, peculiar, and somewhat oleaginous, but in the recent root is said by Dr. Frost to be strong and acrimonious. The taste is bitterish and pungent, leaving an impression of disagreeable acrimony in the mouth and fauces. It imparts its virtues to water and alcohol. Dr. Frost thinks that the active principle is somewhat volatile, and states that the root loses much of its activity when long kept.

Medical Properties and Uses. In large doses, stillingia is emetic and cathartic, in smaller doses alterative, with some influence over the secretions. It has been long popularly used in South Carolina; but was first introduced to the notice of the profession by Dr. Thomas Young Simons, in a paper published in the *American Medical Recorder* for April, 1828 (vol. xiii. p. 312), as a valuable alterative remedy in syphilitic affections, and others ordinarily requiring the use of mercury. Dr. Simons's statements have been confirmed and extended by Dr. A. Lopez, of Mobile (*N. Orleans Med. and Surg. Journ.*, iii. 40), and Dr. H. R. Frost, of Charleston, S. C. (*South. Journ. of Med. and Pharm.* for November, 1846). From the reports in its favour there seems no reason to doubt the efficacy of this medicine in secondary syphilis, scrofula, cutaneous diseases, chronic hepatic affections, and other complaints ordinarily benefited by alterative medicines. It may be given in substance, decoction, or tincture; but the two latter forms are preferable. The dose of the powder is stated at from fifteen to thirty grains. The decoction, made by slowly boiling an ounce of the bruised root in three pints of water to a pint, may be given in the quantity of one or two fluidounces three or four times a day, increased as the stomach will bear it.

The dose of a tincture, made with two ounces of the root and a pint of diluted alcohol, is about a fluidrachm. Stillingia is sometimes advantageously combined with sarsaparilla and other alteratives. W.

DATURA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solanaceæ.

Gen. Ch. Corolla funnel-shaped, plaited. *Calyx* tubular, angular, deciduous. *Capsule* four-valved. *Willd.*

Datura Stramonium. Willd. *Sp. Plant.* i. 1008; Bigelow, *Am. Med. Bot.* i. 17; Woodv. *Med. Bot.* p. 197, t. 74. The *thornapple* is an annual plant, of rank and vigorous growth, usually about three feet high, but in a rich soil sometimes six feet or more. The root is large, whitish, and furnished with numerous fibres. The stem is erect, round, smooth, somewhat shining, simple below, dichotomous above, with numerous spreading branches. The leaves, which stand on short round footstalks in the forks of the stem, are five or six inches long, of an ovate-triangular form, irregularly sinuated and toothed at the edges, unequal at the base, dark-green on the upper surface, and pale beneath. The flowers are large, axillary, solitary, and peduncled; having a tubular, pentangular, five-toothed calyx, and a funnel-shaped corolla with a long tube, and a waved plaited border, terminating in five acuminate teeth. The upper portion of the calyx falls with the deciduous parts of the flower, leaving its base, which becomes reflexed, and remains attached to the fruit. This is a large, fleshy, roundish-ovate, four-valved, four-celled capsule, thickly covered with sharp spines, and containing numerous seeds, attached to a longitudinal receptacle in the centre of each cell. It opens at the summit.

There are two varieties of this species of Datura, one with a green stem and white flowers; the other with a dark-reddish stem minutely dotted with green, and purplish flowers striped with deep purple on the inside. The latter, however, is considered by some botanists as a distinct species, being the *D. Tatula* of Linnæus. The properties of both are the same.*

It is doubtful to what country this plant originally belonged. Many European botanists refer it to North America, while we in return trace it to the old continent. Nuttall considers it as having originated in South America or Asia; and it is probable that its native country is to be found in some portion of the East. It is said to grow wild abundantly in Southern Russia, from the borders of the Black Sea eastward to Siberia. Its seeds, being retentive of life, are taken in

* M. Naudin maintains that they are distinct species, always retaining their distinctive characters, the one of green stems and pure white flowers, the other dark-purple stems and violet-tinted flowers. The two species were crossed by M. Naudin, who obtained hybrids, which, though of twice the size of their parents, were in other respects intermediate between them; and, when these hybrids were cultivated, they showed a constant tendency to return to the original; out of a considerable number of seedlings, many being real D. Stramonium, and nearly as many D. Tatula. (See *Am. Journ. of Pharm.*, Sept. 1865, p. 341.)—*Note to the thirteenth edition.*

the earth put on shipboard for ballast from one country to another, not unfrequently springing up upon the passage, and thus propagating the plant in all regions which have any commercial connection. In the United States it is found everywhere in the vicinity of cultivation, frequenting dung-heaps, the road-sides and commons, and other places where a rank soil is created by the deposited refuse of towns and villages. Its flowers appear from May to July or August, according to the latitude. Where the plant grows abundantly, its vicinity may be detected by the rank odour which it diffuses to some distance around. All parts of it are medicinal. The leaves and seeds only are now officinal; the root having been omitted in the recent revision of the U. S. Pharmacopœia. The leaves may be gathered at any time from the appearance of the flowers till the autumnal frost. In this country the plant is generally known by the name of *Jamestown weed*, derived probably from its having been first observed in the neighbourhood of that old settlement in Virginia. In Great Britain it is called *thornapple*.

1. The *fresh leaves* when bruised emit a fetid narcotic odour, which they lose upon drying. Their taste is bitter and nauseous. These properties, together with their medical virtues, are imparted to water and alcohol. Water distilled from them, though possessed of their odour in a slight degree, is destitute of their active properties. They contain, according to Promnitz, 0·58 per cent. of gum, 0·6 of extractive, 0·64 of green starch, 0·15 of albumen, 0·12 of resin, 0·23 of saline matters, 5·15 of lignin, and 91·25 of water. The leaves, if carefully dried, retain their bitter taste.

2. The *seeds* are small, kidney-shaped, flattened on the sides, of a dark-brown almost black colour, inodorous, and of the bitter, nauseous taste of the leaves, with some degree of acrimony. They are much more energetic in their action on the system than the leaves. MM. Hirtz and Hopp inferred, from their experiments, that one part of an extract prepared from them was equal in strength to five parts of an extract prepared in precisely the same manner from the leaves (*Ann. de Thérap.*, A. D. 1862, p. 22). They were analyzed by Brandes, who found, besides a peculiar alkaline principle called *daturia*, a glutinous matter, albumen, gum, a butyraceous substance, green wax, resin insoluble in ether, fixed oil, bassorin, sugar, gummy extractive, orange-coloured extractive, and various saline and earthy substances Chemists, however, have failed to obtain the daturia of Brandes by his own process; and Berzelius states that it has been admitted, even by that chemist himself, to be nothing more than phosphate of magnesia. (*Traité de Chimie*, vi. 319.) But Geiger and Hesse succeeded in isolating an alkaline principle, to which the same name has been given, and which Trommsdorff has repeatedly procured by their process.

As described by Geiger and Hesse, *daturia* crystallizes in colourless, inodorous, shining prisms, which, when first applied to the tongue, are bitterish, but ultimately have a flavour like that of tobacco. It is dissolved by 280 parts of cold, and 72 of boiling water, is very soluble in alcohol, and less so in ether. Mr. H. J. Waddington states that daturia, resembling atropia precisely in this respect, melts when heated, remains colourless, and sublimes in perfect crystals. (*Pharm. Journ. and Trans.*, March, 1868, p. 416.) It has been shown to have a poisonous action upon animals, and strongly dilates the pupil. Crystals of it are asserted to have been obtained from the urine of a person fatally poisoned by stramonium. (See *Am. Journ. of Med. Sci.*, xvi. 485.) It may be procured from the seeds in the same manner as *hyoscyamia* from those of Hyoscyamus niger. (See *Hyoscyamus*.) The product is exceedingly small. In the most favourable case, Trommsdorff got only $\frac{1}{50}$ of 1 per cent. According to Dr. A. Von Planta, daturia is identical with atropia, its formula being $C_{34}H_{23}NO_6$. (See *Am. Journ. of Pharm.*, xxiii. 38.) Mr. Morries obtained a poisonous empyreumatic oil by the destructive distillation of stramonium.

Medical Properties and Uses. Stramonium is a powerful narcotic. When taken in quantities sufficient to affect the system moderately, it usually produces more or less cerebral disturbance, indicated by vertigo, headache, dimness or perversion of vision, and confusion of thought, sometimes amounting to slight

delirium or a species of intoxication. At the same time peculiar deranged sensations are experienced about the fauces, œsophagus, and trachea, increased occasionally to a feeling of suffocation, and often attended with nausea. A disposition to sleep is sometimes but not uniformly produced. The pulse is not materially affected. The bowels are rather relaxed than confined, and the secretions from the skin and kidneys not unfrequently augmented. These effects pass off in five or six hours, or in a shorter period, and no inconvenience is subsequently experienced. In poisonous doses, this narcotic produces cardialgia, excessive thirst, nausea and vomiting, a sense of strangulation, anxiety and faintness, partial or complete blindness with dilatation of the pupil, sometimes deafness, flushing and swelling of the face, headache, vertigo, delirium sometimes of a furious, sometimes of a whimsical character, tremors of the limbs, palsy, and ultimately stupor and convulsions. In a case recorded by Dr. C. B. Faust, the whole surface of the body was of a scarlet colour. (*Charleston Journ. & Rev.*, ix. 745.) From all these symptoms the patient may recover; but they have frequently terminated in death. To evacuate the stomach by emetics or the stomach-pump is the most effectual remedy. What has before been said as to the destructive effects of the caustic alkalies upon the active principle of belladonna and hyoscyamus is applicable to their influence on stramonium. (See *pages* 171 and 474.) Opium exercises the same antagonistic influence upon the operation of this poison as on that of belladonna. (See *Belladonna*, page 171.)

Though long known as a poisonous and intoxicating herb, stramonium was first introduced into regular practice by Baron Störck, of Vienna, who found some advantage from its use in mania and epilepsy. Subsequent observation has confirmed his estimate of the remedy; and numerous cases are on record in which benefit has accrued from it in these complaints. Other diseases in which it has been found beneficial are neuralgic and rheumatic affections, dysmenorrhœa, syphilitic pains, cancerous sores, and spasmodic asthma. In the last complaint it has acquired considerable reputation. It is employed only during the paroxysm, which it very often greatly alleviates or altogether subverts. The practice was introduced into Great Britain from the East Indies, where the natives are in the habit of smoking the dried root and lower part of the stem of *Datura ferox*, in the paroxysms of this distressing complaint. The same parts of *D. Stramonium* were substituted, and found equally effectual. To prepare the roots for use, they are quickly dried, cut into pieces, and beaten so as to loosen the texture. The dried leaves answer the same purpose. They are smoked by means of a common tobacco-pipe These and other narcotic leaves have also been used in the shape of cigars. The smoke produces a sense of heat in the lungs, followed by copious expectoration, and attended frequently with temporary vertigo or drowsiness, and sometimes with nausea. The remedy should never be used in plethoric cases, unless preceded by ample depletion, and in no case where there is determination to the head. Dangerous and even fatal consequences have resulted from its incautious or improper use; and General Gent, who was instrumental in introducing the practice into England, is said at last to have fallen a victim to it. Stramonium has sometimes been given by the stomach in the same complaint. It is used by Dr. H. D. W. Pawling in the treatment of delirium tremens, and, as represented in the inaugural dissertation of his pupil Dr. G. W. Holstein, with great success. Dr. Pawling employs a decoction of the leaves.

Externally the medicine is used advantageously as an ointment or cataplasm in irritable ulcers, inflamed tumours, swelling of the mammæ, and painful hemorrhoidal affections. Dr. J. Y. Dortch, of North Carolina, has found it very useful in tinea capitis. (*Thesis*, Feb. 1846.) By American surgeons it is very frequently applied to the eye, in order to produce dilatation of the pupil, previously to the operation for cataract; and is found equally efficacious with belladonna. For this purpose the extract, mixed with lard, is generally rubbed over the eyelid, or a solution of it dropped into the eye.

Of the parts of the plant employed, the seeds are the most powerful. They may be given in the dose of a grain twice a day; and an extract made by evapo-

rating the decoction, in one-quarter or half the quantity. The dose of the powdered leaves is two or three grains. The inspissated juice of the fresh leaves is more commonly prescribed than any other preparation, and may be administered in the quantity of one grain. (See *Extractum Stramonii Foliorum.*) There is also an officinal tincture, to which the reader is referred. The dose should be gradually increased till the narcotic operation becomes evident, or relief from the symptoms of the disease is obtained. Fifteen or twenty grains of the powdered leaves, and a proportionate amount of the other preparations, have often been given daily without unpleasant effects.

Daturia has been employed for obtaining the effects whether of stramonium or belladonna. M. Jobert has found it three times as strong as atropia, less apt to disturb vision than belladonna, and at the same time more constant and lasting in its operation. (*Ann. de Thérap.*, A. D. 1863, p. 28.)

STYRAX. *U. S.*

Storax.

The prepared juice of Liquidambar orientale. *U. S.*

Off. Syn. STYRAX PRÆPARATUS. *Prepared Storax.* A balsam, obtained from the bark of Liquidambar orientale. Purified by means of rectified spirit and straining. *Br.*

Storax, *Fr., Germ.;* Storace, *Ital.;* Estoraque, *Span.*

Until recently it was generally admitted that storax was obtained from Styrax officinale; and it has not been determined that this plant does not yield a variety of the drug; but both the U. S. and Br. Pharmacopœias now ascribe the storax in ordinary use to Liquidambar orientale; and we shall, therefore, give a brief description of both plants.

STYRAX. See BENZOINUM.

Styrax officinale. Willd. *Sp. Plant.* ii. 623; Woodv. *Med. Bot.* p. 291, t. 101. This species of Styrax is a tree which rises from fifteen to twenty-five feet in height, sends off many branches, and is covered with a rough gray bark. The leaves are alternate, petiolate, entire, oval, pointed, bright-green on their upper surface, white with a cotton-like down upon the under, about two inches in length, and an inch and a half in breadth. The flowers are united in clusters of three or four at the extremities of the branches. They are white, and bear considerable resemblance to those of the orange. The tree is a native of Syria and other parts of the Levant, and has been naturalized in Italy, Spain, and the south of France, where, however, it does not yield balsam. This circumstance induced some naturalists to doubt whether *Styrax officinale* is the real source of storax; and, as the *Liquidambar styraciflua* of this country affords a balsam analogous to that under consideration, Bernard de Jussieu conjectured that the latter might be derived from another species of the same genus, *L. orientale* of Lamarck, which is more abundant in Syria than the *Styrax.* This conjecture has since been confirmed; and storax is now officinally referred to that plant.

LIQUIDAMBAR. *Sex. Syst.* Monœcia Polyandria.—*Nat. Ord.* Amentaceæ, *Juss.;* Balsamaceæ, *Lindley.*

Gen. Ch. MALE. *Amentum* conical, surrounded by a four-leaved involucre; *corolla* none; *filaments* numerous. FEMALE. *Amentum* globose, with a four-leaved involucre; *calyx* one-leafed, urceolate, two-flowered; *styles* two; *capsules* two, surrounded at the base by the calyx, one-celled, many-seeded.

Liquidambar orientale. Miller, *Dict.* no. 2; *Pharm. Journ.*, xvi. 462. The *oriental sweet-gum* is a tree of from twenty to forty feet high, with palmate leaves, of which each division is obscurely three-lobed. They are serrate, perfectly smooth, bright-green and shining on the upper surface, and pale on the

under. The tree is a native of Asia Minor, in the southwestern parts of which it forms large forests. It yields the variety of the drug called *liquid storax.*

Accounts somewhat differ as to the mode of collecting the balsam. They agree, however, in the point, that, the outer bark having been removed, the inner bark is scraped off and submitted to pressure. According to Mr. Maltass, the bark is first pressed cold in horse-hair bags, after which hot water is thrown over them, and they are again pressed. Lieutenant Campbell states that the inner bark is first boiled with water, and, a portion of the balsam which rises having been skimmed off, is then pressed so as to extract the remainder. The residuary bark, after expression, is dried in the sun, and employed in various parts of Turkey for fumigation. It is the drug known in commerce as *Storax bark* or *Cortex Thymiamatis.* (Hanbury, *Pharm. Journ.*, xvi. 463.) The balsam is sent in casks to Constantinople, Smyrna, and other ports of the Levant.

Several kinds of storax have been described. The purest was the *storax in grains*, which was in whitish, yellowish-white, or reddish-yellow tears, about the size of a pea, opaque, soft, adhesive, and capable of uniting so as to form a mass. Another variety, formerly called *styrax calamita*, from the circumstance, as is supposed, that it was brought wrapped in the leaves of a kind of reed, consisted of dry and brittle masses, formed of yellowish agglutinated tears, in the interstices of which was a brown or reddish matter. The French call it *storax amygdaloïde.* This and the preceding variety had a pleasant odour like that of vanilla. Neither of them, however, is now found in the markets. It is possible that one or both of these varieties may have been the product of Styrax officinale; but there seems to be no certainty on this point.

A third variety, which is sometimes sold as the *styrax calamita*, is in brown or reddish-brown masses of various shapes, light, friable, yet possessing a certain degree of tenacity, and softening under the teeth. Upon exposure, it becomes covered upon the surface with a white efflorescence of benzoic acid. It evidently consists of sawdust, united either with a portion of the balsam, or with other analogous substances. As found in our shops, it is usually in the state of a coarse, soft, dark-coloured powder, mingled with occasional light friable lumps of various magnitude, and containing very little of the balsam. When good, it should yield, upon pressure between hot plates, a brown resinous fluid having the odour of storax. The source of this variety is not precisely known. Mr. Hanbury states that some of it is prepared at Trieste by mixing the residue of the liquidambar bark remaining after expression, and reduced to coarse powder, with genuine liquid storax. (*Pharm. Journ.*, April, 1863, p. 438.)

A fourth variety, which, under the name of *liquid storax*, is the one commonly used, is a semi-fluid, adhesive substance, brown or almost black upon the surface exposed to the air, but of a slightly greenish-gray colour within, and of an odour somewhat like that of Peruvian balsam, though less agreeable. It is kept in jars. The source of liquid storax was till recently quite uncertain. Some supposed it to be derived by decoction from the young branches of *Liquidambar styraciflua;* but a specimen of the juice of this plant, brought from New Orleans, which we had an opportunity of inspecting, had an odour entirely distinct from that of the substance under consideration. According to Landerer, who resides in Greece, liquid storax is obtained in the islands of Cos and Rhodes from the bark and young twigs of Styrax officinale, by subjecting them to pressure. But Mr. Daniel Hanbury, in a communication to the *Pharmaceutical Journal* (xvi. 422), has shown this to be an error; none whatever of the balsam being collected in those islands. It has been stated above that liquid storax had been referred to *Liquidambar orientale;* and from specimens of the plant furnishing the balsam, collected by Mr. Maltass, and sent by him to Mr. Hanbury, there can scarcely be a doubt of the correctness of this reference.

As found in the shops, storax is usually so much adulterated as to require purification before it can be used; and, both in the U. S. and British Pharmacopœias, processes were formerly given for its preparation. But in the recent editions these processes have been abandoned; and the U. S. authorities content

themselves with directing, in the Materia Medica Catalogue, the "prepared juice" of the plant; the British, the "balsam purified by means of rectified spirit and straining." Whenever not originally pure enough for use, it should be dissolved in alcohol, the solution strained, and the alcohol distilled off to a certain extent, and then completely evaporated at a gentle heat.

General Properties. Storax has a fragrant odour and aromatic taste. It melts with a moderate heat, and, when the temperature is raised, takes fire and burns with a white flame, leaving a light spongy carbonaceous residue. It imparts its odour to water, which it renders yellow and milky. Its active constituents are dissolved by alcohol and ether. Newmann obtained from 480 grains of storax 120 of watery extract; and from an equal quantity, 360 grains of alcoholic extract. Containing volatile oil and resin, and yielding benzoic or cinnamic acid by distillation, it is entitled to be ranked as a balsam. Besides oil, resin, and benzoic acid, Reinsch found in styrax calamita, gum, extractive, lignin, a matter extracted by potassa, water, and traces of ammonia. Simon found in liquid storax cinnamic acid, and a resinous substance, which he considered identical with the *styracin* of Bonastre. According to Toel, styracin is a compound of cinnamic acid with a peculiar substance which he calls *styrone*, and is in composition perfectly analogous to the natural fats. (*Chem. Gaz.*, July 2, 1849.) Strecker gives the name of styrone to a substance resulting from the action of caustic potassa on liquid storax. He states that, if this be oxidized by exposing spongy platinum moistened with it in the liquid state to the air the odour of oil of cinnamon is perceived, evincing the production of a portion of that oil. (See *Pharm. Journ.*, xv. 180.) The volatile oil of storax, denominated *styrol*, is obtained by distilling the liquid balsam with water and carbonate of soda, this salt being added to retain the cinnamic acid. It is a mobile, limpid fluid, with the odour of liquid storax, and a burning taste. It has the sp. gr. 0·924, and boils at 294° F. (*Gmelin's Handbook*, xiii. 2.)

Medical Properties and Uses. This balsam is a stimulating expectorant, and was formerly recommended in phthisis, chronic catarrh, asthma, and amenorrhœa; but it is very seldom used at present, except as a constituent of the compound tincture of benzoin. It has been highly praised as a remedy in diphtheria and pseudomembranous croup. Liquid storax has been recommended in gonorrhœa and leucorrhœa as equally effectual with copaiba, and less disagreeable. From ten to twenty grains may be given twice a day, and the dose gradually increased. The same variety of storax, mixed with olive oil, has been found by Dr. H. Schultze, of Magdeburg, effectual in the cure of itch; the death of the insect resulting from a single thorough rubbing of the surface in twenty-four hours, and the eruption then subsiding spontaneously. (*Am. Journ. of Med. Sci.*, July, 1867, p. 258.)

SULPHUR LOTUM. *U. S.*

Washed Sulphur.

Sublimed sulphur, thoroughly washed with water. *U. S.*

SULPHUR SUBLIMATUM. *U. S., Br.*

Sublimed Sulphur.

Sulphur, prepared from crude or rough sulphur by sublimation. *Br.*

Brimstone; Soufre, *Fr.;* Schwefel, *Germ.;* Zolfo, *Ital.;* Azufre, *Span.*

The officinal forms of sulphur are the *sublimed*, the *washed*, and the *precipitated*. The sublimed and washed sulphur will be noticed in this place; the precipitated, in *Part* II. among the Preparations.

Natural States. Sulphur is very generally disseminated throughout the mineral kingdom, and is almost always present, in minute quantity, in animal and

vegetable matter. Among vegetables, it is particularly abundant in mustard and other cruciform plants. It occurs in the earth, either native or in combination. When native it is found in masses, translucent or opaque, or in the powdery form mixed with various earthy impurities. In combination it is usually united with certain metals, as iron, lead, mercury, antimony, copper, and zinc, forming compounds called sulphurets. *Native sulphur* is most abundant in volcanic countries, and is hence called *volcanic sulphur*. The most productive mines of sulphur are found in Sicily, at Solfatara in the kingdom of Naples,* and in the Roman States. A large mine of native sulphur has been opened in California, about twenty miles from Santa Barbara, and seven from the seacoast. (*Am. Journ. of Pharm.*, March, 1862, p. 176.) Near the borax lake in California (see *Sodæ Boras*, page 815) is an elevation, where the deposition of sulphur is constantly going on from vapours issuing from innumerable crevices in a decomposed volcanic rock, the surface of which is so far covered with the deposited matter as to give the mass the appearance of a bank of sulphur. It is called "Sulphur Banks," and will no doubt largely contribute this material to commerce in future times. (Prof. J. D. Whitney, *Ibid.*, May, 1866, pp. 237–8.) Already works are in operation for preparing the sulphur.

Extraction, &c. Sulphur is obtained either from sulphur earths, or from the native sulphurets of iron and copper, called iron and copper pyrites. The sulphur earths are placed in earthen pots, set in oblong furnaces of brickwork. From the upper and lateral part of each pot, a tube proceeds obliquely downwards, which communicates with the upper part of a similar pot, situated outside the furnace, and perforated near its bottom, to allow the melted sulphur to flow into a vessel containing water, conveniently placed to receive it. Fire being applied, the sulphur rises in vapour, leaving the impurities behind, and, being condensed again, flows from the perforated pot into the vessel containing the water. Sulphur, as thus obtained, is called *crude sulphur*, and contains about one-twelfth of its weight of earthy matter. For purification it is generally melted in a cast iron vessel. When the fusion is complete, the impurities subside, and the purer sulphur is dipped out and poured into cylindrical wooden moulds, which give it the form of solid cylinders, about an inch in diameter, called in commerce *roll sulphur* or *cane brimstone*. The dregs of this process, ground to powder, constitute a very impure kind of sulphur, of a gray colour, called in the shops *sulphur vivum* or *horse brimstone*.

The above process purifies the sulphur but imperfectly. At the same time it causes a considerable loss; as the dregs just mentioned contain a large proportion of sulphur. A more eligible mode of purification consists in distilling the crude sulphur from a large cast iron still, set in brickwork over a furnace, and furnished with an iron head. The head has two lateral communications, one with a chamber of brickwork, the other with an iron receiver immersed in water, which is constantly renewed to cool it sufficiently to cause the sulphur to condense in the liquid form. When the tube between the still and receiver is shut, and that communicating with the chamber is open, the sulphur condenses on its walls in the form of an impalpable powder, and constitutes *sublimed sulphur* or *flowers of sulphur*. If, on the other hand, the communication with the chamber is closed, and that with the receiver opened, the sulphur condenses in the latter in the fused state, and, when cast in cylindrical moulds, forms the *roll sulphur* of commerce.

The extraction of sulphur from the bisulphuret of iron (iron pyrites) is performed by distilling it in stone-ware cylinders. Half the sulphur contained in the bisulphuret is volatilized by the heat, and conducted, by means of an adapter, into vessels containing water, where it condenses. The residue of the mineral is employed for making sulphate of iron, or green vitriol. In the island of Anglesea, large quantities of sulphur are obtained from copper pyrites in the pro-

* On a recent visit (A. D. 1861) to Solfatara, one of the authors was informed that sulphur was no longer obtained from this extinct volcano; and certainly no works for its extraction were then in operation. (*Note to the twelfth edition.*)

cess for extracting that metal. The furnaces in which the ore is roasted are connected by horizontal flues with chambers, in which the volatilized sulphur is condensed. Each chamber is furnished with a door, through which the sulphur is withdrawn once in six weeks.

Crude sulphur comes to this country principally from Messina, in Sicily, and the ports of Italy. Roll sulphur and the flowers are usually brought from Marseilles. Good Sicilian sulphur does not contain more than 3 per cent. of impurity, consisting chiefly of earths. Crude sulphur is employed by the manufacturers of sulphuric acid; and, as it is very variable in quality, it becomes important to ascertain its exact value. This may be done by drying a given weight of it, and submitting it to combustion. The weight of the incombustible residue, added to that lost in drying, gives the amount of impurity.

Properties. Sulphur is a non-metallic element, susceptible of several allotropic states. In its ordinary state it is a brittle solid, of a pale-yellow colour, permanent in the air, and exhibiting a crystalline texture and shining fracture. It has a slight taste, and a perceptible smell when rubbed. When pure its sp. gr. is about 2; but it varies a little in density in its different allotropic states. Occasionally, from impurity, its sp. gr. is as high as 2·35. Its eq. number is 16, and its symbol S. It is a bad conductor of heat, and becomes negatively electric by friction. The melting point of sulphur varies with its allotropic state, which is readily altered by heat. Pure sulphur melts and sublimes at 180°. (Guy, *Pharm. Journ.*, Feb. 1868, p. 375.) In ordinary sulphur, which is a mixture of the element in different allotropic states, the melting point varies from 232° to 248°. If heated above its melting point, it undergoes, in proportion to the heat applied, a progressive change, which will cause it, upon slow cooling, to solidify at a temperature lower than that at which it was melted; and, if it be remelted, it will be found to have a higher melting point than before. Melted sulphur is perfectly limpid, and of a bright-yellow colour. When sulphur is melted, and, after partial cooling, the crust formed on its surface is pierced, and the fluid portion poured out, it may be obtained in slender prismatic crystals, called prismatic sulphur. When sulphur is heated above its melting point, it becomes deeper-coloured and less fluid. At 392°, it has a deep-brown colour, and is so viscid that it cannot be poured from the containing vessel. If the temperature be still further increased, the sulphur resumes its fluidity, but retains its brown colour. Finally, when the temperature reaches 752°, it boils in close vessels, forming a yellow vapour, and may be distilled. If melted sulphur, heated above 392°, is suddenly cooled by being poured out into water, it becomes a reddish-brown plastic mass, with alteration of properties, called *soft sulphur* (*viscid sulphur*), which is employed in taking impressions of medals, &c. This form of sulphur resumes the hard state, but not its original colour, after the lapse of a few days, or suddenly if heated to about 212°. Sulphur is insoluble in water, but soluble in alkaline solutions, petroleum, rectified coal naphtha, the fixed oils, oil of turpentine and other volatile oils, alcohol and ether, chloroform, and bisulphide of carbon. Its best solvent is bisulphide of carbon, from solution in which it crystallizes generally in octohedrons, a form belonging to a different system from the prism, obtained by crystallizing melted sulphur by cooling. Hence sulphur is said to be dimorphous.

The allotropic states of sulphur have been studied chiefly by Brodie, Magnus and Weber, and Berthelot. These states are induced, for the most part, by heat, and are distinguished by the crystalline form of the sulphur, and by its solubility or non-solubility in bisulphide of carbon. According to the corrected determinations of Magnus and Weber, there are four allotropic states of sulphur, which they distinguish by the names of prismatic, octohedral, crummy, and insoluble sulphur. *Prismatic sulphur* forms the greater part of ordinary sulphur. It is soluble in bisulphide of carbon. If heated just to its point of fusion, it will have a coinciding melting and solidifying point at 248°. (*B. C. Brodie.*) *Octohedral sulphur* may be obtained from freshly made soft sulphur, by acting on it with bisulphide of carbon, which dissolves it in part. This solution, by

distilling off a portion of the bisulphide, yields, on cooling, octohedral sulphur. The melting point of this sulphur is 238°; but it is difficult to get it correctly, owing to the facility with which octohedral sulphur is changed by heat into the prismatic, with the effect of raising the melting point. (*B. C. Brodie.*) The solution, when no more crystals can be obtained from it, still contains sulphur, which may be separated as a cellular amorphous mass, called crummy sulphur, by the spontaneous evaporation of the solvent. *Crummy sulphur* forms from 2 to 5 per cent. of the soft sulphur; and, though obtained from its solution in bisulphide of carbon, cannot be redissolved in it, even at the boiling temperature. *Insoluble sulphur* is the name given to that part of the soft sulphur which is left undissolved by the bisulphide, amounting to between one-third and nearly one-half of the former. Mr. Brodie was unable to determine the melting point of this sulphur, but found it considerably above 248°, or the melting point of prismatic sulphur. Flowers of sulphur contain about one-third of their weight of insoluble sulphur. Crummy sulphur is either yellow or red, according as it is obtained from a soft sulphur which has been once or several times melted and poured out into water. What Magnus formerly called *red sulphur* is a red modification of crummy sulphur. Red and black sulphur are no longer considered by Magnus as allotropic states of sulphur; but rather as sulphur modified by the presence of a minute proportion of foreign matter. This opinion is founded on the recent discovery of Mitscherlich, confirmed by Magnus, that a number of substances, especially the fats and oils, when heated with sulphur, give it a red or black colour. Thus, one part of tallow, heated with 3000 parts of sulphur, imparts to it an intensely red colour; and the same proportion of paraffin changes it to red or black. So minute is the quantity of foreign matter, capable of producing this change, that Magnus asserts that sulphur, touched by the hands, will be coloured red by the greasy matter thereby imparted, upon being heated to 572°. *Black sulphur* forms a soft, greasy, ductile mass, which after a time solidifies, when it assumes a glassy appearance. (See *Chem. Gaz.*, May 15, 1854, and *Philos. Mag.*, Supplement, Jan. 1857.)

The physical properties of sulphur are remarkably modified by heating it in contact with a minute proportion of certain other substances. MM. Moutier have ascertained that, heated with $\frac{1}{400}$ of iodine, it becomes, on cooling, soft, plastic, and in great measure insoluble in bisulphide of carbon. The same authors found that many other substances have a similar effect on sulphur; as naphthalin, paraffin, creasote, camphor, and oil of turpentine; the quantity of the substance required varying from $\frac{1}{400}$ to $\frac{1}{600}$; and the necessary temperature being different with the substances used; camphor requiring 230° C., and naphthalin and oil of turpentine much more. After cooling, a paste is obtained, black, soft, plastic, ductile, which passes very slowly into the hard and brittle state of ordinary sulphur. (*Journ. de Pharm. et de Chim.*, 4e sér., i. 288, A. D. 1865.)

Sulphur takes fire at about the temperature of 300°, and burns with a blue flame, combining with the oxygen of the air, and giving rise to a peculiar gaseous acid, called sulphurous acid. The combinations of sulphur are numerous, and among the most powerful agents of chemistry. It forms with oxygen four principal acids, the *hyposulphurous*, *sulphurous*, *hyposulphuric*, and *sulphuric;* with hydrogen, *sulphohydric acid* (*hydrosulphuric acid* or *sulphuretted hydrogen*); and with the metals, various *sulphurets*. Some of the sulphurets are analogous to acids, others to bases; and these different sulphurets, by combining with each other, form compounds which, from their analogy to salts, are called by Berzelius *sulpho-salts*.

An extremely sensitive test of this element is a solution of molybdate of ammonia in muriatic acid, diluted with water, which is rendered blue by contact with even a trace of sulphur. (*Journ. de Pharm.*, Mai, 1862, p. 367.)

Sulphur, when obtained by roasting the native sulphurets, sometimes contains arsenic, and is thereby rendered poisonous. Sicilian sulphur, being volcanic, is not subject to this impurity. The common English roll sulphur is

sometimes made from iron pyrites, and is then apt to contain orpiment (*tersulphuret of arsenic*). This impurity may be detected by heating the suspected sulphur with nitric acid. The arsenic, if present, will be converted into arsenic acid; and the nitric solution, diluted with water, neutralized with carbonate of soda, and acidulated with muriatic acid, will give a yellow precipitate of quintosulphuret of arsenic with a stream of sulphuretted hydrogen. A precipitate may be more readily obtained from the nitric solution, if, after neutralization, sulphurous acid be added, which will convert the arsenic acid into the arsenious. This is more easily decomposed by the sulphuretted hydrogen; but the precipitate obtained will now be the tersulphuret. Sulphur, when perfectly pure, is wholly volatilized by heat, and soluble without residue in oil or turpentine. According to Dr. Playfair, a solution of nitroprusside of sodium is a delicate test for the alkaline sulphurets, producing with them a violet tint. The late Prof. Bailey, of West Point, employed the same test for detecting sulphur in any compound. The substance suspected to contain it is fused with carbonate of soda, with the addition of carbonaceous matter if necessary. If sulphur be present it will be converted into sulphuret of sodium; and, upon the addition of a small portion of the fused mass to a drop of the nitroprusside, the characteristic violet tint will be produced.

Sublimed sulphur, usually called *flowers of sulphur* (*flores sulphuris*), is in the form of a crystalline powder of a fine yellow colour. It is always contaminated with a little sulphuric acid, which is formed at the expense of the oxygen of the air contained in the subliming chambers. Accordingly, it always reddens litmus; and, if the acid is present in considerable quantity, sometimes cakes. It may be freed from acidity by careful ablution with hot water, when it becomes the officinal washed sulphur.

Washed sulphur is placed in the list of Materia Medica of the U. S. Pharmacopœia, with an explanatory note, that it is sublimed sulphur, thoroughly washed with water. Washed sulphur has the general appearance of sublimed sulphur, and is wholly volatilized by heat. When properly prepared it does not affect litmus, and undergoes no change by exposure to the air.

Medical Properties and Uses. Sulphur is laxative, diaphoretic, and resolvent. It is supposed to be rendered soluble by the soda of the bile. M. Miahle at present teaches that it is carried into the circulation by the fatty matters in the alimentary canal which dissolve it. (*Med. T. and Gaz.*, June, 1868, p. 642.) It evidently passes off by the pores of the skin; as is shown by the fact that silver, worn in the pockets of patients under a course of it, becomes blackened with a coating of sulphuret. The stools which it occasions are usually solid, and it is gentle in its operation, unless it contain a good deal of acid, when it may cause griping; and the liability of the sublimed sulphur to contain acid, renders it less eligible for exhibition than the washed sulphur, from which all acidity is removed. The diseases in which sulphur is principally used are hemorrhoidal affections, atonic gout, chronic rheumatism, chronic catarrh, and asthma. It has also been given as an antiperiodic, being considered as particularly applicable to cases in which the apyrexia is incomplete. It is also much employed, both internally and externally, in cutaneous affections, especially scabies, for the cure of which it is considered a specific. In these affections, as well as in chronic rheumatism, it is sometimes applied as an air bath, in the form of sulphurous acid gas, the head being protected from its effects. It has been employed with great success, by M. Lagauldric, in diphtheric croup, given freely every hour, simply suspended in water. M. Thevenot finds it promptly effectual in the removal of diphtheric exudation, simply applied locally to the patches. (*Ann. de Thérap.*, A. D. 1867, p. 78.) It is said also to be very useful in lead colic. (*Ibid.*, 1868, p. 108.) The external use of sulphur is strongly recommended by Dr. O'Connor, of London, in sciatica and chronic articular rheumatism. The limb affected is covered with sulphur, and bandaged with new flannel, over which sheets of wadding are wrapped. The dressing should not be taken off for several days; as its earlier removal would interfere

with the absorption of the sulphur, on which its curative effect depends. (*Lancet*, Am. ed., June, 1857, p. 507.) The dose of sulphur is from one to three drachms, mixed with syrup or molasses, or taken in milk. It is often combined with bitartrate of potassa, or with magnesia.

According to M. Hannon, of Brussels, *soft sulphur*, recently prepared, possesses valuable therapeutic properties, not as a laxative, but as a stimulant to the circulation, lungs, and skin, far more active than ordinary sulphur. The dose of soft sulphur is from twenty to fifty grains, given in the form of pill. It has also been successfully employed for filling the hollows of carious teeth. (*Pharm. Journ.*, xvii. 330.)

Sulphur is consumed in the arts, principally in the manufacture of gunpowder and sulphuric acid.

SUMBUL RADIX. *Br.*

Sumbul Root.

The dried transverse sections of the root of a plant the botanical history of which is unknown. Imported from Russia and also from India. *Br.*

Under the name of *sumbul* or *jatamansi*, a root has long been used in India, Persia, and other parts of the East, as a perfume, an incense in religious ceremonies, and medicinally. It is the product of an unknown plant, supposed to be umbelliferous, and, from the character of the root, to grow in low wet places. The plant is said to inhabit no part of British India, but the regions to the north and east of it, as Nepaul, Bootan, Bucharia, &c. The root is taken northward to Russia, and reaches the rest of Europe through St. Petersburg. The physicians of Moscow and St. Petersburg were the first to employ it on the continent of Europe. Dr. Granville first introduced it to the notice of the profession in Great Britain and this country. It has recently also been imported into England from India, whither it was brought from a great distance in the interior.

The medicine comes in transverse sections, from two to four or five inches in diameter, and from an inch to an inch and a half in length, with a dusky, light-brown, wrinkled epidermis, and an interior porous structure, consisting of coarse, irregular, easily separable fibres. The fresh cut surface of a transverse section presents, within the epidermis, an exterior white and spotted layer, and an inner yellow substance which forms the greater part of the root. Examined by means of a microscope, it exhibits translucent points which probably represent starch granules. Sumbul has a strong odour, much resembling that of musk, which it retains when long kept; and hence the name of *musk-root* sometimes attached to it. The taste, at first feebly sweetish, becomes after a time bitterish and balsamic, but not disagreeable; and a strong aroma is developed under mastication, diffusing itself with a sensation of warmth through the mouth and throat, and rendering the breath fragrant. This effect, however, is much diminished by time. That brought from India differs somewhat from the Russian, being of closer texture, more dense and firm, and of a reddish tint. (*Am. Journ. of Pharm.*, xxiv. 174; from *Pharm. Journ.*)

The root has been analyzed by Reinsch and other German chemists, and found to contain volatile oil, two balsamic resins, one soluble in alcohol, the other in ether, wax, gum, starch, a bitter substance soluble in water and alcohol, a crystallizable acid, which Reinsch proposes to call *sumbulic acid*, and saline matter. The musklike odour seems to be connected with the balsamic resins, and probably depends on some principle associated with them not yet isolated. The volatile oil yielded by distillation has a taste like that of peppermint.

The virtues of the drug appear to be those of a nervous stimulant. It is used by the Russian physicians in low fevers of a typhous character, and in asthenic cases of dysentery and diarrhœa. It has also been employed by them with asserted success in malignant cholera. The authors, on the occasion of a visit in the summer of 1853 to St. Petersburg, were informed by Dr. Thielmann, physician to the Hospital of St. Peter and St. Paul, that he depended mainly on this remedy in the treatment of delirium tremens, having found it superior in its composing influence over that complaint even to opium. Dr. Granville recommends it in gastric spasms, hysteria, chlorosis, amenorrhœa, dysmenorrhœa, palsy of the limbs, epilepsy, and other nervous disorders. It is given in substance, infusion, decoction, and alcoholic and ethereal tincture. There seems to be no great precision in relation to the dose; but it is inferrible, from the accounts of the drug, that it may be used very much as we use valerian. The facts above stated are taken chiefly from a pamphlet by Dr. Granville, published in London, A. D. 1850.

Dr. Murawieff, of Russia, prepares the resin, which he considers as the active principle, by macerating the root first in water, and then in a solution of carbonate of soda, washing it well with cold water, drying it, treating it with alcohol, filtering the tincture, adding a little lime and again filtering, separating the lime by sulphuric acid, agitating with animal charcoal, again filtering, distilling off nearly all the alcohol, mixing the residuum with water, driving off the remaining alcohol, and, finally, washing the precipitate with cold water, and drying it. The resin thus obtained is whitish, translucent, softening between the fingers, combustible without residue, of an acid taste, and an aromatic smell, like that of the root. Dr. Murawieff gives it in the dose of a grain or two, in the form of pill, three or four times a day, with or without opium, and has found it useful in chronic bronchitis and pneumonia slow of resolution, in the moist asthma of old, anemic, and scorbutic patients, in atonic dysentery, leucorrhœa, hypochondriasis, and hysteria. (*Dub. Quart. Journ.*, Feb. 1855, p. 252; from *Med. Zeit. Russland.*) Prof. Procter has published a formula for a fluid extract, of which the dose is from 15 minims to a fluidrachm. (*Am. Journ. of Pharm.*, xxvii. 233.)

Off. Syn. TABACI FOLIA. *Leaf Tobacco.* The dried leaves of Virginian tobacco, Nicotiana Tabacum. *Br.*

Tabac, *Fr.;* Tabak, *Germ.;* Tobacco, *Ital.;* Tobaco, *Span.*

NICOTIANA. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Solanaceæ.

Gen. Ch. Corolla funnel-shaped, with the border plaited. *Stamens* inclined. *Capsules* two-valved, two-celled. *Willd.*

Nicotiana Tabacum. Willd. *Sp. Plant.* i. 1014; Bigelow, *Am. Med. Bot.* ii 171; Woodv. *Med. Bot.* p. 208, t. 77. The tobacco is an annual plant, with a large fibrous root, and an erect, round, hairy, viscid stem, which branches near the top, and rises from three to six feet in height. The leaves are numerous, alternate, sessile, and somewhat decurrent, very large, ovate-lanceolate, pointed, entire, slightly viscid, and of a pale-green colour. The lowest are often two feet long, and six inches broad. The flowers are disposed in loose terminal panicles, and are furnished with long, linear, pointed bractes at the divisions of the peduncle. The calyx is bell-shaped, hairy, somewhat viscid, and divided at its summit into five pointed segments. The tube of the corolla is twice as long as the calyx, of a greenish hue, swelling at top into an oblong cup, and ultimately expanding into a five-lobed, plaited, rose-coloured border. The whole corolla is very viscid The filaments incline to one side, and support oblong anthers. The pistil consists of an oval germ, a slender style longer than the stamens, and a cleft stigma.

The fruit is an ovate, two-valved, two-celled capsule, containing numerous reniform seeds, and opening at the summit. The leaves are the part employed. The seeds, examined by F. M. Brandt, yielded no narcotic principle, though a protein-like substance contained in them was thought, by its decomposition, to produce nicotia. (*Neues Jahrb. für Pharm.*, xxi. 42) Prof. Procter also failed to find nicotia in the seeds. (*Proceed. of Am. Pharm. Assoc.*, 1858, p. 296.)

There is good reason to believe that this plant is a native of tropical America, where it was found by the Spaniards upon their arrival. It is at present cultivated in most parts of the world, and nowhere more abundantly than within the limits of the United States. Virginia is, perhaps, the region most celebrated for its culture. The young shoots, produced from seeds thickly sown in beds, are transplanted into the fields during the month of May, and set in rows with an interval of three or four feet between the plants. Through the whole period of its growth, the crop requires constant attention. The development of the leaves is promoted by removing the top of each plant, and thus preventing it from running into flower and seed. The harvest is in August. The ripe plants, having been cut off above their roots, are dried under cover, and then stripped of their leaves, which are tied in bundles, and packed in hogsheads. While hung up in the drying houses, they undergo a curing process, consisting in exposure to a considerable degree of heat, through which they become moist, or in other words are said to sweat, after which they are dried for packing.

Two varieties of this species are mentioned by authors, one with narrow, the other with broad leaves; but they do not differ materially in properties. Great diversity in the quality of tobacco is produced by difference of soil and mode of cultivation; and several varieties are recognised in commerce. Other species also of Nicotiana are cultivated, especially *N. rustica* and *N. paniculata*, the former of which is said to have been the first introduced into Europe, and is thought to have been cultivated by the aborigines of this country, as it is naturalized near the borders of some of our small northern lakes. The *N. quadrivalvis* of Pursh affords tobacco to the Indians of the Missouri and Columbia rivers; and *N. fruticosa*, a native of China, was probably cultivated in Asia before the discovery of this continent by Columbus. The latter species is said by Mr. John Le Conte to be that from which the best Cuba tobacco is obtained. (*Am. Journ. of Pharm.*, Sept. 1859; from *Proceed. of Acad. of Nat. Sci.*)

Properties. Tobacco, as it occurs in commerce, is of a yellowish-brown colour, a strong narcotic penetrating odour which is wanting in the fresh leaves, and a bitter, nauseous, and acrid taste. These properties are imparted to water and alcohol. They are injured by long boiling; and the extract is, therefore, relatively feeble. An elaborate analysis of tobacco was made by Vauquelin, who discovered in it, among other ingredients, an acrid, volatile, colourless liquid, slightly soluble in water, very soluble in alcohol, and supposed to be the active principle. It was separated by a complicated process, of which, however, the most important step was the distillation of tobacco juice with potassa. In the results of this distillation, Vauquelin recognised alkaline properties, which he ascribed to ammonia, but which were, in part at least, dependent upon the acrid principle alluded to. To this principle the name of *nicotin* was given; but its alkalinity was not ascertained till a subsequent period. Another substance was obtained by Hermstadt by simply distilling water from tobacco, and allowing the liquid to stand for several days. A white crystalline matter rose to the surface, which, upon being removed, was found to have the odour of tobacco, and to resemble it in effects. It was fusible, volatilizable, similar to the nicotin of Vauquelin in solubility, and without alkaline or acid properties. It was called *nicotianin* by Hermstadt, and appears to partake of the nature of volatile oils. Two German chemists, Posselt and Reimann, subsequently analyzed tobacco, and ascertained the alkaline nature of its active principle, which, however, neither they nor Vauquelin obtained in a state of purity. According to these chemists, 10,000 parts of the fresh leaves contain 6 parts of an alkaline substance, which they call *nicotin*, 1 of the *nicotianin* of Hermstadt, 287 of slightly bitter ex-

tractive, 174 of gum mixed with a little malate of lime, 26·7 of green resin 26 of albumen, 104·8 of a substance analogous to gluten, 51 of malic acid, 12 of malate of ammonia, 4·8 of sulphate of potassa, 6·3 of chloride of potassium, 9·5 of potassa, which was combined in the leaves with malic and nitric acids, 16·6 of phosphate of lime, 24·2 of lime which had been combined with malic acid, 8·8 of silica, 496·9 of lignin, traces of starch, and 8828 parts of water. (Berzelius, *Traité de Chimie.*) According to M. E. Goupet, tobacco contains also a little citric acid. (*Chem. Gaz.*, Aug. 1846, p. 319.) The nicotin obtained by Vauquelin, and by Posselt and Reimann, was a colourless, volatile liquid, and, as subsequently ascertained by Henry and Boutron, was in fact an aqueous solution of the alkaline principle in connection with ammonia. It was reserved for these chemists to obtain nicotin, or *nicotia*, as it should now be called, in a state of purity. It exists in tobacco combined with an acid in excess, and in this state is not volatile.*

The following was the process employed by the Messrs. Henry and Boutron. Five hundred parts of smoking tobacco were exposed to distillation, in connection with about 6000 parts of water and 200 parts of caustic soda; the heat applied being at first very moderate, and afterwards increased to the boiling point. The product of the distillation was received in a vessel containing about 30 or 40 parts of sulphuric acid, diluted with 3 times its weight of water; and the process was continued till nearly one-half of the liquid had come over. The product, in which care was taken to preserve a slight excess of acid, was evaporated to about 100 parts, and then allowed to cool. A slight deposit which had formed was separated by filtration, an excess of caustic soda was added, and the liquor again distilled. A colourless, very volatile, acrid liquor now came over, which, being concentrated under the receiver of an air-pump, lost the ammonia which accompanied it, and assumed a syrupy consistence, and more or less of the colour of amber. In the liquid, after a few days, minute crystalline plates formed; but, in consequence of their affinity for moisture, it was difficult to isolate them. This liquid was pure nicotia. M. Debize obtains it by passing a current of steam through a mixture of tobacco and lime, contained in a cylinder, and condensing the vapour by a worm connected with the opposite extremity of the cylinder from that at which the steam enters. The resulting liquid, which contains the nicotia, together with ammonia and some undetermined bases, is neutralized with sulphuric acid, then concentrated, and treated with ammonia and ether, by means of which an ethereal solution of nicotia is obtained. As this base is insoluble in solution of sulphate of ammonia, the solution of nicotia separates, and, rising to the surface, may be removed. The alkaloid may afterwards be obtained pure by rectification. (*Journ. de Pharm.*, Oct. 1860, p. 281.)

Nicotia. (*Nicotina. Nicotin.*) This is a colourless or nearly colourless fluid; of the sp. gr. 1·048; remaining liquid at 22° F.; of little smell when cold; of an exceedingly acrid burning taste, even when largely diluted; entirely volatilizable, and, in the state of vapour, very irritant to the nostrils, with an odour recalling that of tobacco;† inflammable; very soluble in water, alcohol, ether, the fixed oils, and oil of turpentine; strongly alkaline in its reaction; and capable of forming crystallizable salts with the acids. These salts are deliquescent, have a burning and acrid taste, and, like the salts of ammonia, lose a portion of their base by heat. Nicotia contains a much larger proportion of nitrogen

* M. Liecke determines the proportion of nicotia in any specimen of tobacco as follows. He treats the dry leaves three times successively with water acidulated with sulphuric acid, and evaporates the liquid to the consistence of an extract. The extract is agitated with its volume of alcohol, and the tincture is filtered through paper previously washed with alcohol. It contains all the nicotia in the state of sulphate. After evaporating the alcohol, he decomposes the sulphate by caustic potassa in a distillatory apparatus of glass, which is heated gradually, by means of an oil-bath, to 260° C., and saturates the nicotia received by dilute sulphuric acid. (*Journ. de Pharm. et de Chim.*, Déc. 1867, p 451.)—*Note to the thirteenth edition.*

† It boils at 482° F., undergoing, however, partial decomposition in the process; but, heated in a stream of hydrogen, it distils over unaltered between 212° and 392° F. (Frezenius, *Am. Journ. of Pharm.*, Jan. 1867, p. 27.)

than most of the other organic alkalies. Its formula is $N_2C_{20}H_{14}$, and combining number consequently 162. In its action on the animal system, it is one of the most virulent poisons known. A drop of it, in the state of concentrated solution, was sufficient to destroy a dog; and small birds perished at the approach of a tube containing it. In man, it is said to destroy life, in poisonous doses, in from two to five minutes. Tannin forms with it a compound of but slight solubility, and might be employed as a counter-poison. It exists in tobacco in small proportion. Henry and Boutron found different varieties of tobacco to give products varying from 3·8 to 11·28 parts in 1000. It has been found in the seeds, and in very small proportion in the root. (See *Journ. de Pharm.*, xxii. 689.) There can be little doubt that tobacco owes its activity to this alkaloid.* It has been employed as a poison. For a very interesting account of it in all its toxicological relations, the reader is referred to a memoir by Orfila, translated by Dr. Lee, and published in the *N. Y. Journ. of Med.* (N. S., ix. 112, 219, and 369). A more recent paper on the same subject, by Dr. A. S. Taylor, is contained in the *Pharmaceutical Journal* for June, 1859 (p. 620). Nicotia has the remarkable property of resisting decomposition amid the decaying tissues of the body, and was detected by Orfila in the bodies of animals destroyed by it two or three months after their death. Prof. F. F. Mayer, of New York, has concluded from his experiments, that nicotia is the active principle in all parts of the plant both before and after curing. (*Proc. Am. Pharm. Assoc.*, 1865.)

Nicotianin is probably the odorous principle of tobacco. Posselt and Reimann prepared it by distilling six pounds of the fresh leaves with twelve pounds of water, till one-half of the liquid passed over, then adding six pounds more of water, and again distilling, and repeating this process three times. The nicotianin was obtained to the amount of eleven grains, floating on the surface of the water. It was a fatty substance, having the smell of tobacco-smoke, and an aromatic somewhat bitter taste. It was volatilizable by heat, insoluble in water, soluble in alcohol and ether, and not affected by the dilute acids, but dissolved by solution of potassa. This was not obtained by Henry and Boutron. It produces sneezing when applied to the nostrils, and a grain of it swallowed by Hermstadt occasioned giddiness and nausea.

The presence of sulphuretted hydrogen and hydrocyanic acid in tobacco-smoke has been demonstrated by Dr. A. Vogel and C. Reischauer. (See *Am. Journ. of Pharm.*, Jan. 1859, p. 76.)

When distilled at a temperature above that of boiling water, tobacco affords an empyreumatic oil, which Mr. Brodie proved to be a most virulent poison. A single drop, injected into the rectum of a cat, occasioned death in about five minutes, and double the quantity, administered in the same manner to a dog, was followed by the same result. This oil is of a dark-brown colour, and an acrid taste, and has a very peculiar smell, exactly resembling that of tobacco-pipes which have been much used. It has been shown to contain nicotia. (*Ann. de Chim. et de Phys.*, 3e sér., ix. 465.)

It is quite certain that tobacco leaves undergo considerable chemical changes during the processes of curing, and preparation for use. Thus, the characteristic odour of ordinary tobacco is entirely different from that of the fresh leaves, and must be owing to the generation of a new volatile principle. The propor-

* M. Schloesing obtained a much larger proportion than that stated above, by the following process. Tobacco is exhausted by boiling water, the infusion evaporated to a semi-solid consistence, and the extract shaken with twice its volume of alcohol of 36°. Two layers form, of which the upper contains all the nicotia. This is decanted, most of the alcohol evaporated, and alcohol anew added in order to precipitate certain matters. The extract is treated with a concentrated solution of potassa, and, after cooling, is shaken with ether, which dissolves the nicotia. To the ethereal solution powdered oxalic acid is added, which unites with the nicotia, and separates in the form of a syrupy mass. This, being washed with ether, treated with potassa, taken up by water, and distilled in a water-bath, yields the nicotia, which may be obtained pure by rectification in a current of hydrogen. (*Journ. de Pharm.*, 3e sér., xii. 157.) Orfila, in his memoir on nicotia, states that Havana tobacco yields 2 per cent. of this alkaloid, Maryland 2·3 per cent., and Virginia 6·9 per cent.

tion, too, of nicotia contained in prepared tobacco is asserted to be greater than in the fresh. It appears that a kind of fermentation takes place in the leaves, by which certain pre-existing principles are converted into nicotianin and possibly nicotia. A similar change is probably produced during the combustion of tobacco; for M. Malapert obtained, from the condensed products of a portion of common French smoking tobacco which he burned, as much as 9 per cent. of nicotia, while the proportion obtained by the ordinary process seldom exceeds 2 per cent., and the highest proportion of which we have seen any account is 6·9 per cent. (See *Am. Journ. of Pharm.*, xxvii. 119.) It has even been made a question, whether nicotia exists at all in the fresh growing leaves; but this question has been experimentally decided in the affirmative by Prof. Procter (*Proceed. of Am. Pharm. Assoc.*, 1858, p. 300); and Prof. Mayer, of N. York, has experimentally determined that the nicotia exists as largely in the plant before as after curing; indeed, believes that it is somewhat diminished in the process, probably in part if not altogether by volatilization. (*Ibid.*, A. D. 1865.)

The distinguishing character of tobacco, as given in the Br. Pharmacopœia, is that, when distilled with solution of potassa, it yields an alkaline fluid, having the peculiar odour of nicotia, and giving precipitates with perchloride of platinum and tincture of galls.

Medical Properties and Uses. Tobacco unites, with the powers of a sedative narcotic, those of an emetic and diuretic; and produces these effects to a greater or less extent to whatever surface it may be applied. In addition, when snuffed up the nostrils, it excites violent sneezing and a copious secretion of mucus; when chewed, it irritates the mucous membrane of the mouth, and increases the flow of saliva; and, when injected into the rectum, it sometimes operates as a cathartic. Moderately taken, it quiets restlessness, calms mental and corporeal inquietude, and produces a state of general languor or repose, which has great charms for those habituated to the impression. In larger quantities, it gives rise to confusion of the head, vertigo, stupor, faintness, nausea, vomiting, and general depression of the nervous and circulatory functions, which, if increased, eventuates in alarming and even fatal prostration. The symptoms of its excessive action are severe retching, with the most distressing and continued nausea, great feebleness of pulse, coolness of the skin, fainting, and sometimes convulsions. It probably operates both through the medium of the nervous system, and by entering the circulation. As its local action is stimulant, we can thus account for the fact, that it excites the function of the kidneys, at the same time that it reduces the nervous and secondarily the arterial power. The experiments of Brodie lead to the inference that the function of the heart is affected by tobacco, through the medium of the nervous system; for, in a decapitated animal in which the circulation was sustained by artificial respiration, the infusion injected into the rectum did not diminish the action of the heart; while, on the contrary, this organ almost immediately ceased to contract, when an equal dose of the poison was administered to a healthy animal. Mr. Brodie observed a remarkable difference between the operation of the infusion and that of the empyreumatic oil. After death from the former the heart was found completely quiescent, while it continued to act with regularity for a considerable time after apparent death from the latter. We may infer from this fact, either that there are two poisonous principles in tobacco, or that a new narcotic product is formed during its destructive distillation. In cases of poisoning from tobacco, the indications are, after the evacuation of the poison, to support the system by external and internal stimulants, and to allay irritation of stomach by opiates.

The use of tobacco was adopted by the Spaniards from the American Indians. In the year 1560, it was introduced into France by the Ambassador of that country at the court of Lisbon, whose name—Nicot—has been perpetuated in the generic title of the plant. Sir Walter Raleigh is said to have introduced the practice of smoking into England. In the various modes of smoking, chewing, and snuffing, the drug is now largely consumed in every country on the

globe. It must have properties peculiarly adapted to the propensities of our nature, to have thus surmounted the first repugnance to its odour and taste, and to have become the passion of so many millions. When employed in excess, it enfeebles digestion, produces emaciation and general debility, and lays the foundation of serious nervous disorders. The late Dr. Chapman informed us that he had met with several instances of mental disorder, closely resembling delirium tremens, which resulted from its abuse, and which subsided in a few days after it had been abandoned; and Dr. Kirkbride, in the *Annual Report of the Pennsylvania Hospital for the Insane for* 1850, refers to four cases of insanity, the origin of which was ascribed to the abuse of tobacco. Among the ill effects ascribed to the habitual excessive use of tobacco, are premature gray hairs and baldness. (Dr. D. B. Hoffman, *Med. Record.*, Sept. 1, 1868; from *Pacific Med. and Surg. Journ.*) In the form of snuff, tobacco is sometimes so much contaminated with lead, in consequence of being kept in leaden boxes, as to endanger the poisonous effects of that metal. In different kinds of snuff, Dr. A. Vogel has found from 0·014 to 1·025 per cent. of lead. (See *Am. Journ. of Pharm.*, Sept. 1864, p. 422.)

Its remedial employment is less extensive than might be inferred from the variety of its powers. The excessive and distressing nausea which it is apt to occasion, interferes with its internal use; and it is very seldom administered by the stomach. As a narcotic it is employed chiefly to produce relaxation in spasmodic affections. For this purpose the infusion or smoke of tobacco, or the leaf in substance in the shape of a suppository, is introduced into the rectum in cases of strangulated hernia, obstinate constipation from spasm of the bowels, and retention of urine from a spasmodic stricture of the urethra. For a similar purpose, the powdered tobacco, or common snuff, mixed with simple cerate, as recommended by the late Dr. Godman, is sometimes applied to the throat and breast in cases of croup; and Dr. Chapman directed the smoking of a cigar in the same complaint, with decided benefit. One of the worst cases of spasm of the rima glottidis which we have seen, and which resisted powerful depletion by the lancet, yielded to the application of a tobacco cataplasm to the throat. A similar application to the abdomen is highly recommended in painters' colic, and has proved useful in hysterical convulsions. Tetanus is said to have been cured by baths made with the decoction of the fresh leaves; and an infusion of the leaves has been given internally with success in a case of poisoning by strychnia. (*Dub. Med. Press*, June 23, 1858.) The relaxation produced by smoking, in a person unaccustomed to it, was very happily resorted to by Dr. Physick, in a case of obstinate and long-continued dislocation of the jaw; and the same remedy has frequently been found useful in the paroxysm of spasmodic asthma. Tobacco has been highly recommended, in the form of cataplasm, in articular gout and rheumatism; and has been employed in the same way, as well as by injection, in cases of obstinate verminose affections. As an emetic it is seldom employed, unless in the shape of a cataplasm to the epigastrium, to assist the action of internal medicines, in cases of great insensibility of stomach. As a diuretic it was used by Fowler in dropsy and dysury; but the practice is not often imitated. There is no better errhine than tobacco, for the ordinary purposes for which this class of medicines is employed. As a sialagogue, it is beneficial in rheumatism of the jaws, and often relieves toothache by its anodyne action. It is also used externally, in the shape of cataplasm, infusion, or ointment, in cases of tinea capitis, psora, and some other cutaneous affections. The empyreumatic oil mixed with simple ointment, in the proportion of twenty drops to the ounce, has been applied with advantage, by American practitioners, to indolent tumours and ulcers; but, in consequence of its liability to be absorbed, and to produce unpleasant effects on the system, it should be used with great caution. (See *Oleum Tabaci.*) This remark is applicable to all the modes of employing tobacco; particularly to the injection of the infusion into the rectum, which has caused death in several instances. It is even more dangerous than a proportionate quantity introduced into the stomach; as, in the latter case, the poison is more

apt to be rejected. Even the external application of the leaves or powder is not without danger, especially when the cuticle is removed. A case of death is on record, occurring in a child eight years old, in consequence of the application of the expressed juice of the leaves to the head, for the cure of tinea capitis. Death has also been produced by the inhalation of the smoke.

Five or six grains of powdered tobacco will generally act as an emetic; but the remedy is not given in this shape. The infusion used in dropsy by Fowler was made in the proportion of an ounce to a pint of boiling water, and given in the dose of sixty or eighty drops. The officinal infusion, which is employed for injection, is much weaker. (See *Infusum Tabaci.*) A wine and an ointment of tobacco are directed by the U. S. Pharmacopœia.

TAMARINDUS. *U. S., Br.*

Tamarind.

The preserved fruit of Tamarindus Indica. *U. S.* The preserved pulp of the fruit. *Br.*

Tamarins, *Fr.;* Tamarinden, *Germ.;* Tamarindi, *Ital.;* Tamarindos, *Span.*

TAMARINDUS. *Sex. Syst.* Monadelphia Triandria. — *Nat. Ord.* Fabaceæ or Leguminosæ.

Gen. Ch. Calyx four-parted. *Petals* three. *Nectary* with two short bristles under the filaments. *Legume* filled with pulp. *Willd.*

Tamarindus Indica. Willd. *Sp. Plant.* iii. 577; Woodv. *Med. Bot.* p. 448, t. 161. The tamarind tree is the only species of this genus. It rises to a great height, sends off numerous spreading branches, and has a beautiful appearance. The trunk is erect, thick, and covered with a rough, ash-coloured bark. The leaves are alternate and pinnate, composed of many pairs of opposite leaflets, which are almost sessile, entire, oblong, obtuse, unequal at their base, about half an inch long by a sixth of an inch broad, and of a yellowish-green colour. The flowers, which are in small lateral racemes, have a yellowish calyx, and yellow petals beautifully variegated with red veins. The fruit is a broad, compressed, reddish ash-coloured pod, much curved, from two to six inches long, with numerous brown, flat, quadrangular seeds, contained in cells formed by a tough membrane. Exterior to this membrane is a light-coloured acid pulpy matter, between which and the shell are several tough ligneous strings, running from the stem to the extremity of the pod, the attachment of which they serve to strengthen. The shells are fragile and easily separated.

Tamarindus Indica appears to be a native of the East and West Indies, Egypt, and Arabia, though believed by some to have been imported into America. Dr. Barth, the African traveller, found it abundant in the interior of Africa, and one of the greatest ornaments of Negroland. (*Travels in Africa*, Am. ed., 1857, i. 418.) De Candolle is doubtful whether the East and West India trees are of the same species. It is stated by writers that the pods of the former are much larger than those of the latter, and have a greater number of seeds; the East India tamarinds containing six or seven, those from the West Indies rarely more than three or four. We found, however, in a parcel of the latter in our possession, numerous pods with from eight to ten seeds, and the number generally exceeded four The fruit is the officinal portion.

Tamarinds are brought to us chiefly, if not exclusively, from the West Indies, where they are prepared by placing the pods, previously deprived of their shell, in layers in a cask, and pouring boiling syrup over them. A better mode, sometimes practised, is to place them in stone jars, with alternate layers of powdered sugar. They are said to be occasionally prepared in copper boilers.

Properties. Fresh tamarinds, which are sometimes, though rarely, brought to this country, have an agreeable sour taste, without any mixture of sweetness. As we usually find them, in the preserved state, they form a dark-coloured ad-

hesive mass, consisting of syrup mixed with the pulp, membrane, strings, and seeds of the pod, and of a sweet acidulous taste. The seeds should be hard, clean, and not swollen, the strings tough and entire, and the smell without mustiness. From the analysis of Vauquelin, it appears that in 100 parts of the pulp of tamarinds, independently of the sugar added to them, there are 9·40 parts of citric acid, 1·55 of tartaric acid, 0·45 of malic acid, 3·25 of bitartrate of potassa, 4·70 of gum, 6·25 of jelly, 34·35 of parenchymatous matter, and 27·55 of water; so that the acidity is owing chiefly to citric acid. It is said that copper may sometimes be detected in preserved tamarinds, derived from the boilers in which they are occasionally prepared. Its presence may be ascertained by the reddish coat which it imparts to the blade of a knife immersed in the tamarinds.

Medical Properties and Uses. Tamarinds are laxative and refrigerant, and infused in water form a highly grateful drink in febrile diseases. Convalescents often find the pulp a pleasant addition to their diet, and useful by preserving the bowels in a loose condition. It is sometimes prescribed in connection with other mild cathartics, and is one of the ingredients in the confection of senna. Though frequently given with infusion of senna to cover its taste, it is said to weaken its purgative power; and the same observation has been made of its influence upon the resinous cathartics in general. From a drachm to an ounce or more may be taken at a dose.

TANACETUM. *U. S. Secondary.*

Tansy.

The herb of Tanacetum vulgare. *U. S.*

Tanaisie, *Fr.;* Gemeiner Rheinfarrn, Wurmkraut, *Germ.;* Tanaceto, *Ital., Span.*

Tanacetum. *Sex. Syst.* Syngenesia Superflua. — *Nat. Ord.* Compositæ-Senecionideæ, *De Candolle;* Asteraceæ, *Lindley.*

Gen. Ch. Receptacle naked. *Pappus* somewhat emarginate. *Calyx* imbricate, hemispherical. *Corolla* rays obsolete, trifid. *Willd.*

Tanacetum vulgare. Willd. *Sp. Plant.* iii. 1814; Woodv. *Med. Bot.* p. 66, t. 27. This is a perennial herbaceous plant, rising two or three feet in height. The stems are strong, erect, obscurely hexagonal, striated, often reddish, branched towards the summit, and furnished with alternate, doubly pinnatifid leaves, the divisions of which are notched or deeply serrate. The flowers are yellow, and in dense terminal corymbs. Each flower is composed of numerous florets, of which those constituting the disk are perfect and five-cleft, those of the ray very few, pistillate, and trifid. The calyx consists of small, imbricated, lanceolate leaflets, having a dry, scaly margin. The seeds are small, oblong, with five or six ribs, and crowned with a membranous pappus.

Tansy is cultivated in our gardens, and grows wild in the roads and in old fields; but was introduced from Europe, where it is indigenous. It is in flower from July to September.

There is a variety of the plant with curled leaves, which is said to be more grateful to the stomach than that above described, but has less of the peculiar sensible properties of the herb, and is probably less active.

The odour of tansy is strong, peculiar, and fragrant, but much diminished by drying; the taste is warm, bitter, somewhat acrid, and aromatic. These properties are imparted to water and alcohol. According to Peschier, the leaves contain volatile oil, fixed oil, wax or stearin, chlorophyll, yellow resin, yellow colouring matter, tannic and gallic acids, bitter extractive, gum, lignin, and a peculiar acid which he calls *tanacetic*, and which precipitates lime, baryta, oxide of lead, and oxide of copper. The medical virtues of the plant depend on the bitter extractive and volatile oil. The latter, when separated by distillation, has a greenish-yellow colour, with the flavour of the plant, is lighter than water, and deposits camphor upon standing. The seeds contain the largest proportion of the bitter principle, and the least of volatile oil. According to Zeller, one

pound of the fresh herb, in flower, yields upon an average twenty-four grains of oil. (*Cent. Blatt*, 1855, p. 206.)

Medical Properties and Uses. Tansy has the medical properties of the aromatic bitters. It has been recommended in intermittents, hysteria, amenorrhœa, and as a preventive of arthritic paroxysms; but at present it is chiefly used as an anthelmintic, and in this country is little employed, for any purpose, in regular practice. The seeds are said to be most effectual as a vermifuge. The leaves have proved, in the hands of Dr. C. Prentice Uhle, to possess extraordinary powers as a local remedy in arresting epistaxis, the simple odour being sometimes sufficient to check the hemorrhage. (*Med. and Surg. Reporter*, May 25, 1867, p. 442.) The dose of the powder is from thirty grains to a drachm two or three times a day; but the infusion is more frequently administered. A fatal case of poisoning with half an ounce of oil of tansy is recorded in the *Medical Magazine* for November, 1834. Frequent and violent clonic spasms were experienced, with much disturbance of respiration; and the action of the heart gradually became weaker till death took place from its entire suspension. No inflammation of the stomach or bowels was discovered upon dissection. (*Am. Journ. of the Med. Sci.*, xvi. 256.) Two other fatal cases have since been recorded, one in which more than a fluidounce was taken, the other only a fluidrachm. In both death followed speedily, preceded by coma and violent convulsions. In two of the three cases above referred to, the oil seems to have been taken to produce abortion, but no such effect followed in either. (*Ibid.*, xxiii. 136, and xxiv. 279.) Dr. Pendleton records a case, in which death resulted to a negress of twenty-one from a considerable quantity of strong decoction of tansy taken internally. W.

TAPIOCA. *U. S.*

Tapioca.

The fecula of the root of Janipha Manihot. *U. S.*

Janipha. *Sex. Syst.* Monœcia Monadelphia.—*Nat. Ord.* Euphorbiaceæ.

Gen. Ch. Calyx campanulate, five-parted. *Stamens* ten, distinct, alternately shorter. *Stigmas* three, many-lobed. *Fruit* three-celled, with solitary seeds (Lindley, *Med. and Œconom. Bot.*, 82.)

Botanists have generally followed Kunth in separating this genus from Jatropha. Its name was derived from the Indian designation of another species.

Janipha Manihot. Curtis's *Bot. Mag.* 3071.—*Jatropha Manihot.* Willd. *Sp. Plant.* iv. 562. This is the *cassava* plant of the West Indies, the *mandioca* or *tapioca* of Brazil. It is a shrub about six or eight feet high, with a very large, white, fleshy, tuberous root, which often weighs thirty pounds. The stem is round, jointed, and furnished at its upper part with alternate petiolate leaves, deeply divided into three, five, or seven oval-lanceolate, very acute lobes, which are somewhat wavy upon their borders, deep-green on their upper surface, glaucous and whitish beneath. The flowers are in axillary racemes.

Janipha Manihot is a native of South America, and is cultivated extensively in the West Indies, Brazil and other parts of tropical America, and in Liberia, for the sake of its root, which is much employed as an article of food. The plant is of quick growth, and the root arrives at perfection in about eight months. There are two varieties, distinguished by the names of *sweet* and *bitter*. The root of the former may be eaten with impunity; that of the latter, which is most extensively cultivated, abounds in an acrid milky juice, which renders it highly poisonous if eaten in the recent state. By MM. Henry and Boutron-Charlard it has been ascertained that the bitter cassava owes its poisonous properties to hydrocyanic acid. (*Journ. de Pharm.*, xxii. 119.) Both varieties contain a large proportion of starch. The root is prepared for use by washing, scraping, and grating or grinding it into a pulp, which, in the bitter variety, is submitted to pressure so as to separate the deleterious juice. It is now in the state of meal or powder, which is made into bread, cakes, or puddings. As the poisonous prin-

ciple is volatile, the portion which may have remained in the meal is entirely dissipated by the heat employed in cooking. The preparation denominated tapioca among us is obtained from the expressed juice. This, upon standing, deposits a powder, which, after repeated washings with cold water, is nearly pure starch. It is dried by exposure to heat, which renders it partly soluble in cold water, and enables it to assume its characteristic consistence. When dried without heat, it is pulverulent, and closely resembles the fecula of arrow-root.

Tapioca is in irregular, hard, white, rough grains, possessing little taste, partially soluble in cold water, and affording a fine blue colour when iodine is added to its filtered solution. The partial solubility in cold water is owing to the rupture of the starch-granules by heat. Examined under the microscope, the granules appear partly broken, partly entire. The latter are muller-shaped, about the two-thousandth of an inch in diameter, more uniform in size than the granules of most other varieties of fecula, with a distinct hilum, which is surrounded by rings, and cracks in a stellate manner. *Tapioca meal*, called sometimes Brazilian arrow-root, and by the French *moussache*, is the fecula dried without heat. Its granules are identical with those already described. Being nutritious, and at the same time easy of digestion, and destitute of irritating properties, tapioca forms an excellent diet for the sick and convalescent. It is prepared for use by boiling it in water. Lemon-juice and sugar are usually grateful additions; and in low states of disease or cases of debility, it may be advantageously impregnated with wine and nutmeg or other aromatic.

A factitious tapioca is found in the shops, consisting of very small, smooth, spherical grains, and supposed to be prepared from potato starch. It is sold under the name of *pearl tapioca*. W.

TARAXACUM. *U.S.*

Dandelion.

The root, gathered in the autumn, of Taraxacum Dens-leonis. *U. S.*

Off. Syn. TARAXACI RADIX. *Dandelion Root.* The fresh and dried roots of Taraxacum Dens Leonis, gathered between September and February. *Br.*

Pissenlit, Dent de lion, *Fr.;* Löwenzahn, *Germ.;* Tarassaco, *Ital.;* Diente de leon, *Span*

LEONTODON. *Sex. Syst.* Syngenesia Æqualis. — *Nat. Ord.* Compositæ-Cichoraceæ, *De Candolle;* Cichoraceæ, *Lindley.*

Gen. Ch. Receptacle naked. *Calyx* double. *Seed-down* stipitate, hairy. *Willd.*

Leontodon Taraxacum. Willd. *Sp. Plant.* iii. 1544; Woodv. *Med. Bot.* p. 39, t. 16. — *Taraxacum Dens-leonis.* De Cand. *Prodrom.* vii. 145. The dandelion is an herbaceous plant, with a perennial fusiform root. The leaves, which spring immediately from the root, are long, pinnatifid, generally runcinate, with the divisions toothed, smooth, and of a fine green colour. The common name of the plant was derived from the fancied resemblance of its leaves to the teeth of a lion. The flower-stem rises from the midst of the leaves, six inches or more in height. It is erect, simple, naked, smooth, hollow, fragile, and terminated by a large golden-coloured flower, which closes in the evening, and expands with the returning light of the sun. The calyx is smooth and double, with the outer scales bent downwards. The florets are very numerous, ligulate, and toothed at their extremities. The receptacle is convex and punctured. The seed-down is stipitate, and at the period of maturity is disposed in a spherical form, and is so light and feathery as to be easily borne away by the wind, with the seeds attached.

This species of Leontodon grows spontaneously in most parts of the globe. It is abundant in this country, adorning our grass-plats and pasture-grounds with its bright-yellow flowers, which, in moist places, show themselves with the first opening of spring, and continue to appear till near the close of summer. All parts of the plant contain a milky bitterish juice, which exudes when they are broken or wounded. The leaves, when very young and blanched by the absence of light during their growth, are tender and not unpleasant to the taste, and on the continent of Europe are sometimes used as a salad. When older and

of their natural colour, they are medicinal. The Pharmacopœias recognise only the root, which is by far the most efficacious part. It should be full grown when collected, and should be employed in the recent state, as it is then most active. It does not, however, as stated by Duncan, lose nearly all its bitterness by drying; and the root dug up in the warmer seasons might, if dried with care, be employed with propriety in the succeeding winter. The juice of the root is thin and watery in the spring; milky, bitter, and spontaneously coagulable in the latter part of summer and autumn; and sweet and less bitter in the winter, when affected by the frost. The months of July, August, and September are, therefore, the proper periods for collecting it.

The fresh full-grown root of the dandelion is several inches in length, as thick as the little finger or thicker, round and tapering, somewhat branched, of a light-brown colour externally, whitish within, having a yellowish ligneous cord running through its centre, and abounding in a milky juice. In the dried state it is dark-brown, much shrunk, wrinkled longitudinally, brittle, and when broken presents a shining somewhat resinous fracture. A transverse section exhibits an exterior cortical portion, thick, spongy, whitish, and marked with concentric rings, and a smaller central portion, ligneous and yellow; though in very old roots the latter is sometimes wanting. It is without smell, but has a sweetish, mucilaginous, bitterish, herbaceous taste. Its active properties are yielded to water by boiling, and do not appear to be injured in the process. The milky juice, examined by John, was found to contain bitter extractive, gum, caoutchouc, saline matters, a trace of resin, and a free acid. Besides these ingredients, starch or inulin, and saccharine matter exist in the root. Mannite, which has been found in the infusion of the root, has been demonstrated by the Messrs. Smith, of Edinburgh, not to pre-exist in the root, but to be formed by spontaneous changes consequent on exposure. A crystallizable principle has been extracted from the juice of the root by M. Pollex, who has named it *taraxacin*. It is bitter and somewhat acrid, fusible but not volatile, sparingly soluble in cold water, but very soluble in boiling water, alcohol, and ether. It is obtained by boiling the milky juice in distilled water, filtering the concentrated liquor, and allowing it to evaporate spontaneously in a warm place. The taraxacin crystallizes, and may be purified by repeated solution and crystallization in alcohol or water. According to Vogel, the intra-cellular substance of the root consists chiefly of pectose, which is the result of a metamorphosis of the substance constituting the membrane of the cells. (*Journ. de Pharm.*, Avril, 1864, p. 362.)

The root of *Aspargia hispida* has been largely substituted for dandelion in England by the herb gatherers (*Pharm. Journ.*, xi. 107); and we are informed that a similar fraudulent substitution is not unfrequent, in this country, of the root of *Cichorium Intibus*, or *chicory*. This is distinguishable from the genuine root by its lighter colour, and greater bitterness. For a particular account of the characteristic properties of the root, by which it may be distinguished from all others, the reader is referred to an article by Mr. K. Bentley, in the *Pharmaceutical Journal* (xvi. 304).

Medical Properties and Uses. Taraxacum is slightly tonic, diuretic, and aperient, and is thought to have a specific action upon the liver, exciting it when languid to secretion, and resolving its chronic engorgements. It has been much employed in Germany, and is a popular remedy with many practitioners in this country. The diseases to which it appears to be especially applicable, are those connected with derangement of the hepatic apparatus, and of the digestive organs generally. In congestion and chronic inflammation of the liver and spleen, in cases of suspended or deficient biliary secretion, and in dropsical affections dependent on obstruction of the abdominal viscera, it appears to be capable of doing good, if employed with a due regard to the degree of excitement. Our own experience is in its favour. An irritable condition of the stomach and bowels, and the existence of acute inflammation, contraindicate its employment. It is usually given in the form of extract or decoction, though some prefer the infusion. (See these preparations in *Part* II.) Bitartrate of potassa is sometimes

added to the decoction when an aperient effect is desired; and aromatics will occasionally be found useful in correcting a tendency to griping or flatulence. The dried root is sometimes mixed, in powder, with ground coffee, the taste of which covers that of the dandelion. It is also used as a substitute for coffee, being powdered and roasted, and then prepared in the same manner.

TEREBINTHINA. *U. S.*

Turpentine.

The concrete juice of Pinus palustris, and of other species of Pinus. *U. S.*

Off. Syn. THUS AMERICANUM. *Common Frankincense.* The concrete turpentine of Pinus Tæda, the Frankincense pine, and Pinus palustris, the Swamp pine. From the Southern States of North America. *Br.*

TEREBINTHINA CANADENSIS. *U. S., Br.*

Canada Turpentine. Balsam of Fir.

The juice of Abies balsamea. *U. S. Canada Balsam.* The turpentine obtained by incision from the stem. *Br.*

Térébenthine, *Fr.;* Terpentin, *Germ.;* Trementina, *Ital., Span.*

The term *turpentine* is usually applied to certain vegetable juices, liquid or concrete, which consist of resin combined with a peculiar essential oil, called *oil of turpentine.* They are generally procured from different species of pine, fir, or larch; though other trees afford products which are known by the same general title, as for instance *Pistacia Terebinthus,* which yields the Chian turpentine. Some French writers extend the name of turpentine to other juices consisting of resin and essential oil, without benzoic or cinnamic acid, as copaiba, balm of Gilead, &c. We shall describe particularly, in this place, only the turpentines which are either now officinal, or have but recently ceased to be so. A brief botanical view of the plants from which they are respectively derived, will be in accordance with the plan of this work. It is proper first to observe that the original genus Pinus of Linnæus has been divided into the three genera, Pinus, Abies, and Larix, which are now very generally recognised, though Lindley unites the two latter in his Flora Medica.

PINUS. *Sex. Syst.* Monœcia Monadelphia. — *Nat. Ord.* Pinaceæ or Coniferæ. *Gen. Ch. Flowers* monœcious. MALES. *Catkins* racemose, compact, and terminal; squamose; the scales staminiferous at the apex. *Stamens* two; the *anthers* one-celled. FEMALES *Catkins* or *cones* simple, imbricated with acuminate scales. *Ovaries* two. *Stigmas* glandular. *Scales* of the cone oblong, club-shaped, woody; umbilicato-angular at the apex. *Seeds* in pairs, covered with a sharp-pointed membrane. *Cotyledons* digitato-partite. *Leaves* two or many, in the same sheath. (*Pereira's Mat. Med.;* from *Bot. Gall.*)

1. *Pinus palustris.* Willd. *Sp. Plant.* iv. 499. — *P. Australis.* Michaux, *N. Am. Sylv.* iii. 133. "Leaves in threes, very long; stipules pinnatifid ramentaceous, persistent; strobiles subcylindrical, armed with sharp prickles."

This is a very large indigenous tree, growing in dry, sandy soils, from the southern part of Virginia to the Gulf of Mexico. Its mean elevation is sixty or seventy feet, and the diameter of its trunk about fifteen or eighteen inches for two-thirds of this height. The leaves are about a foot in length, of a brilliant green colour, and united in bunches at the ends of the branches. The names by which the tree is known in the Southern States are *long-leaved pine, yellow pine,* and *pitch pine;* but the first is most appropriate, as the last two are applied also to other species. This tree furnishes by far the greater proportion of the turpentine, tar, &c. consumed in the United States, or sent from this to other countries. (See *Pix Liquida.*)

2. *Pinus Tæda.* Willd. *Sp. Plant.* iv. 498; Michaux, *N. Am. Sylv.* iii. 156 "Leaves in threes, elongated, with elongated sheaths; strobiles oblong-conical, deflexed, shorter than the leaf; spines inflexed."

This is the *loblolly*, or *old field pine* of the Southern States. It is abundant in Virginia, where it occupies the lands exhausted by cultivation. It exceeds eighty feet in height, has a trunk two or three feet in diameter, and expands into a wide spreading top. The leaves are about six inches long, and of a light-green colour. It yields turpentine in abundance, but less fluid than that which flows from the preceding species.

3. *Pinus sylvestris.* Willd. *Sp. Plant.* iv. 494; Woodv. *Med. Bot.* p. 1, t. 1; Michaux, *N. Am. Sylv.* iii. p. 125. "Leaves in pairs, rigid; strobiles ovate-conical, of the length of the leaves; scales echinate."

This tree, when of full size, is eighty feet high, with a trunk four or five feet in diameter. It inhabits the northern and mountainous parts of Europe. In Great Britain it is called the *wild pine* or *Scotch fir;* the latter name having been given to it from its abundance in the mountains of Scotland. It yields a considerable proportion of the common European turpentine.

In Germany a fibrous substance is prepared from the leaves of this, and other species of Pinus and Abies, called *fir-wool*, and a volatile oil is distilled from them called *fir-wool oil*, which is considerably used, both internally and locally, as a remedy for rheumatism, palsy, chronic catarrh, chronic skin diseases, &c., indeed for the same purposes generally as the oil of turpentine. (See *Am. Journ. of Pharm.*, May, 1863, p. 274.) This oil resinifies on exposure, like oil of turpentine, and varies in sp. gr. from 0·876 to 0·912, according to its source. Its dose, when it is used internally, is from fifteen to twenty drops. An extract of the leaves, denominated *fir-wool extract*, is used for similar purposes. The leaves are made also into wadding and clothing, designated as *fir-wool* from their origin, which are supposed to have some merit in the treatment of similar affections. (*Ibid.*, March, 1867, p. 178.)

Besides the pines above described, various others yield medicinal products. *Pinus maritima* (*P. Pinaster* of Aiton and Lambert), growing in the southern and maritime parts of Europe, yields much of the turpentine, pitch, and tar consumed in France, and is admitted among the officinal plants in the French Codex. From the branches of *Pinus Pumilio*, which inhabits the mountains of eastern and southeastern Europe, a terebinthinate juice exudes spontaneously, called *Hungarian balsam. Pinus Cembra*, or the *Siberian stone-pine* of the Alps and Carpathian mountains, is said to afford the product called *Carpathian balsam;* and the seeds both of that species, and of *Pinus Pinea*, or *stone-pine* of the south of Europe and north of Africa, are used in Europe in desserts, under the name of *pine nuts.* Pinus Lambertiana, of California, produces by exudation a saccharine matter, which has been found to contain a peculiar sweet principle called *pinite.* (*Comptes Rendus*, Sept. 1855.) The *Pinus rigida*, or *pitch pine* of this country, and probably others besides those mentioned, are sometimes employed in the preparation of tar.

ABIES. See PIX BURGUNDICA.

Abies balsamea. Lindley, *Flor. Med.* p. 554. — *A. balsamifera.* Michaux, *N. A. Sylv.* iii. 191. — *Pinus balsamea.* Willd. *Sp. Plant.* iv. 504. "Leaves solitary, flat, emarginate or entire, glaucous beneath, somewhat pectinate, sub-erect above, recurved spreading; cones cylindrical, erect; bractes abbreviate, obovate, conspicuously mucronate, sub-serrulate."

This is the *American silver fir*, or *balm of Gilead tree*, inhabiting Canada, Nova Scotia, Maine, and the mountainous regions further south. It is an elegant tree, seldom rising more than forty feet, with a tapering trunk, and numerous branches, which diminish in length in proportion to their height, and form an almost perfect pyramid. The leaves are six or eight lines long, inserted in rows on the sides and tops of the branches, narrow, flat, rigid, bright-green on their upper surface, and of a silvery whiteness beneath. The cones are large, erect, nearly cylindrical, of a purplish colour, and covered with a

resinous exudation, which gives them a glossy, rich, and beautiful appearance It is from this tree that the *Canada balsam* is obtained.

Several other species of Abies are officinal. *Abies excelsa* of Europe, and *A. Canadensis* of the United States, have already been described as the sources respectively of Burgundy and Canada pitch. (See *Pix Burgundica* and *Pix Canadensis.*) The *A. Picea* (*Abies pectinata* of De Candolle, *A. taxifolia* of the French Codex, *Pinus Picea* of Linnæus), or *European silver fir*, growing in the mountainous regions of Switzerland, Germany, and Siberia, yields the *Strasburg turpentine*, which is much used in some parts of Europe. By the distillation of its cones with water, it also affords a variety of oil of turpentine called in France *essence de templine.* The *Abies nigra* (*Pinus nigra*), or *black spruce* of this country, yields a product, which, though not recognised by the Pharmacopœia, is considerably employed. The substance alluded to is the *essence of spruce*, prepared from the young branches by boiling them in water and evaporating the decoction. It is a thick liquid, having the colour and consistence of molasses, with a bitterish, acidulous, astringent taste. It is used in the preparation of the beverage commonly known by the name of *spruce beer*, which is a pleasant and wholesome drink in summer, and useful in long sea-voyages as a preventive of scurvy.*

Larix. *Sex. Syst.* Monœcia Monadelphia. — *Nat. Ord.* Pinaceæ or Coniferæ.

Gen. Ch. As in Abies, except that the *cotyledons* are simple, and never lobed; the *cones* lateral; the *leaves*, when first expanding, in tufted fascicles, becoming somewhat solitary by the elongation of the new branch. (*Pereira's Mat. Med.*; from *Bot. Gall.*)

Larix Europæa. De Cand. *Flor. Fr.* 2064. — *Abies Larix.* Lamb. *Illust.* t. 785, f. 2. — *Pinus Larix.* Willd. *Sp. Plant.* iv. 503; Woodv. *Med. Bot.* p. 7, t. 4. "Leaves fascicled, deciduous; cones ovate-oblong; margins of the scales reflexed, lacerated; bractes panduriform."

The *European larch* is a large tree, inhabiting the mountains of Siberia, Switzerland, Germany, and the east of France. It yields the *Venice turpentine* of commerce, and a peculiar sweetish substance called in France *Briançon manna*, which exudes spontaneously, and concretes upon its bark. When the larch forests of Russia take fire, a juice exudes from the trunk during their combustion, which concretes, and is called *Orenburgh gum.* It is wholly soluble in water.†

* The following is the formula. Take of essence of spruce *half a pint;* pimento bruised, ginger bruised, hops, each, *four ounces;* water *three gallons.* Boil for five or ten minutes; then strain, and add of warm water *eleven gallons;* yeast *a pint;* molasses *six pints.* Mix, and allow the mixture to ferment for twenty-four hours.

† *Larch Bark.* The inner bark of this species of larch has recently been introduced to the notice of the profession by Dr. Charles Frizel, of Dublin. Examined by Prof. Aldridge, it was found to contain, among other substances, gum, starch, resin, and tannic acid of the kind which precipitates the salts of iron olive-green. Dr. John Stenhouse has obtained from it a peculiar volatile principle, which he has not succeeded in finding in other trees of the pine family, and which, as it has acid properties, though exceedingly feeble, he proposes to name *larixinic acid* (*larixine*). It may be obtained by evaporating an infusion of the bark to the consistence of syrup, and submitting the residue to distillation in a retort of glass or porcelain or a silver alembic, by means of a sand-bath cautiously heated. A portion of larixinic acid comes over and condenses in crystals; but the greater part is dissolved in the liquid distillate. This on careful evaporation deposits the impure acid, which may be purified by pressing it in bibulous paper, again crystallizing from a strong watery solution, and lastly subliming once or twice. Larixinic acid is most abundant in the young bark. It is in beautiful, white, lustrous crystals, often more than an inch long, of a peculiar somewhat empyreumatic smell, and a slightly bitter and astringent taste, inflammable, sublimable at about 200°, soluble in 87·88 parts of water at 59° F., very soluble in boiling water, soluble in cold but much more so in hot alcohol, and sparingly soluble in ether. It readily crystallizes from its solutions. A very singular and characteristic property is that of forming, when added in strong solution, in excess, to baryta-water, a bulky, translucent, gelatinous precipitate, occupying the whole measure of the liquids if concentrated. Its probable formula is $C_{20}H_{10}O_{10}$.

The bark possesses astringent and gently stimulant properties, and is supposed to have a special tendency to the mucous membranes. It has been found peculiarly efficacious in purpura and other hemorrhagic affections, especially hæmoptysis; and has been given in

PISTACIA. See MASTICHE.

Pistacia Terebinthus. Willd. *Sp. Plant.* iv. 752; Woodv. *Med. Bot.* p. 29, t. 12. This is a small tree with numerous spreading branches, bearing alternate, pinnate leaves, which consist of three or four pairs of ovate-lanceolate, entire, acute, smooth, and shining leaflets, with an odd one at the end. The male and female flowers are diœcious, small, and in branching racemes. It is a native of Barbary and Greece, and flourishes in the islands of Cyprus and Chio, the latter of which has given its name to the *Chian turpentine* obtained from the tree. A gall, produced upon this plant by the puncture of an insect, has been used in Eastern Europe in pectoral affections.

We shall treat of the several varieties of turpentine under distinct heads.

1. WHITE TURPENTINE.

Térébenthine de Boston, *Fr.*

The *common American* or *white turpentine* (*Terebinthina, U. S.; Thus Americanum, Br.*) is procured chiefly from *Pinus palustris*, partly also from *Pinus Tæda*, and perhaps other species inhabiting the Southern States. In former times, large quantities were collected in New England; but the turpentine trees of that section of the Union are said to be nearly exhausted; and our commerce has been until recently almost exclusively supplied from North Carolina, and the southeastern parts of Virginia. Within a few years, however, attention has been turned to the collection of this valuable product in Georgia and Florida; and there is no doubt that, in time, an abundant supply will be derived from the vast pine forests which occupy the southern portion of our country bordering on the Gulf of Mexico. The following is the process for obtaining the turpentine as described by Michaux. During the winter, excavations of the capacity of about three pints are made in the trunk of the tree three or four inches from the ground. Into these the juice begins to flow about the middle of March, and continues to flow throughout the warm season, slowly at first, rapidly in the middle of summer, and more slowly again in the autumn. The liquid is removed from these excavations as they fill, and transferred into casks, where it gradually thickens,

bronchitis with copious expectoration, and in diseases of the urinary passages. It has been used also, mixed with soap and glycerin, as a local remedy in psoriasis, chronic eczema, and other cutaneous affections. The usual forms of exhibition are those of extract and tincture, the former in the dose of from 3 to 5 grains, the latter from 30 minims to a fluidrachm or more, every three or four hours. (*Dub. Hosp. Gaz.*, April 15, 1858, and Jan. 15, 1859; *Med. Times and Gaz.*, Nov. 1859, p. 476; and *Am. Journ. of Pharm.*, Nov. 1862, p. 555, &c.)—*Note to the twelfth edition.*

Coniferin. This name has been given to a principle recently discovered by M. Hartig in the cambium of several of the Coniferæ. The species in which it has been found are *Pinus Strobus* and *P. Cembra*, *Abies excelsa* and *A. pectinata*, and *Larix Europæa*; and it probably exists in many others. It is obtained by removing the outer bark, scraping the cambium from the surface of the wood, subjecting this to pressure, boiling the viscid juice to coagulate the albumen, filtering, and evaporating the filtered liquid to one-fifth of its volume. The coniferin is deposited in crystals. The mother-water is very sweet, and contains a saccharine substance closely allied to cane sugar. The crystals are purified by dissolving them in water, decolorizing by animal charcoal, and finally crystallizing from weak alcohol. Coniferin was chemically examined by M. W. Kubel with the following results.

Coniferin is closely allied to salicin, being like it a glucoside. It crystallizes in slender needles, of a silky lustre, containing water of crystallization, which they lose at 212° F., and gradually part with by efflorescence on exposure. It melts at 333° F., and at a higher temperature becomes brown, and ultimately carbonizes with an odour of caramel. It is but slightly soluble in cold water, which takes up only 0·51 per cent., but is readily dissolved by boiling water. It is scarcely soluble in absolute alcohol, and not at all in ether. The watery solution is slightly bitter, deviates the plane of polarization to the left, gives no precipitate with acetate or subacetate of lead, and is not discoloured by chloride of iron. It presents a characteristic reaction. It becomes of a deep-violet with concentrated sulphuric acid, and, on the addition of a little water, gives a precipitate which colours the liquid of a deep indigo blue. It is sufficient to touch with sulphuric acid a fresh cut surface of a branch of one of the Coniferæ, to ascertain the existence of coniferin. (See *Am. Journ. of Pharm.*, May, 1867, p. 261; originally from *Journ. für Prakt. Chem.*, xcvii. 243.)—*Note to the thirteenth edition.*

and ultimately acquires a soft solid consistence. Very large quantities are thus annually procured, sufficient not only to supply the consumption of this country, but also to furnish a valuable export.*

White turpentine, as found in our shops, is yellowish-white, of a peculiar somewhat aromatic odour, and a warm, pungent, bitterish taste. It is somewhat translucent, and of a consistence varying with the temperature. In the middle of summer, it is almost semi-fluid and very adhesive, though brittle; in the winter, it is often so firm and hard as to be incapable of being made into pills without heat. Exposed to the air it ultimately becomes perfectly hard and dry. In the recent state it affords about 17 per cent. of volatile oil. It is apt to contain small pieces of bark, wood, or other impurity.

2. Common European Turpentine.

Térébenthine de Bordeaux, Térébenthine commune, *Fr.;* Gemeiner Terpentin, *Germ.;* Trementina comune, *Ital.;* Trementina comun, *Span.*

This is the *Terebinthina Vulgaris* of the former London Pharmacopœia. It is furnished by several species of pine; but chiefly by *P. sylvestris* and *P. maritima.* From the latter tree it is obtained largely in the maritime districts of the southwest of France, especially in the department of the Landes, and is exported from Bordeaux. Hence it is called in commerce *Bordeaux turpentine.* It is procured by making incisions into the trunk, or removing portions of the bark, and receiving the juice which flows out in small troughs, or in holes dug at the foot of the tree. It is purified by heating, and filtering it through straw, or by exposing it to the sun in a barrel, through holes in the bottom of which the melted turpentine escapes. Thus prepared it is whitish, turbid, thickish, and separates, upon standing, into two parts; one liquid and transparent, the other of a consistence and appearance like those of thickened honey. As found in European commerce it often consists wholly of this latter portion. It speedily hardens on exposure to the air in thin layers. The most liquid specimens are completely solidified by the addition of one part of magnesia to thirty-two of the turpentine. (*Journ. de Pharm.*, xxv. 499.) It is scarcely ever given internally, but furnishes large quantities of oil of turpentine and resin. We do not import it into this country. The substance which the French call *galipot* or *barras*, is that portion of the turpentine which concretes upon the trunk of the tree when wounded, and is removed during the winter. (*Thenard.*) This, when purified by melting with water and straining, takes the name of *yellow* or *white pitch*, or *Burgundy pitch.* When turpentine, whether the European or American, has been deprived of its oil by distillation, the resin which remains is called *rosin*, and sometimes *colophony*, from the Ionian city of Colophon, where it was formerly prepared. It is the officinal resin (*resina*), and is sometimes called yellow resin (*resina flava*). White resin (*resina alba*) is prepared by incorporating this, while in fusion, with a certain proportion of water. (See *Resina*, page 726.) Tar (*pix liquida*) is the turpentine extracted from the wood by slow combustion, and chemically altered by heat. Common pitch (*pix nigra*, or *resina nigra*) is the solid residue left after the evaporation by boiling of the liquid parts of tar.

3. Canada Turpentine.

Canada balsam, Balsam of fir; Baume de Canada, *Fr.;* Canadischer Balsam, Canadischer Terpentin, *Germ.;* Trementina del Canada, *Ital.*

Canada Turpentine (*Terebinthina Canadensis*, U. S., Br.) is the product of *Abies balsamea*, and is collected in Canada and the State of Maine. It is procured by breaking the vesicles which naturally form upon the trunk and branches, and receiving their liquid contents in a bottle. When fresh, it is colourless or slightly yellowish, transparent, of the consistence of thin honey, very tenacious,

* A particular and interesting account of the mode of collecting turpentine, distilling the oil, and preparing tar, practised in North Carolina, is contained in Olmsted's *Journey in the Sea-board Southern States*, N. Y., 1856, p. 339.

of a strong, agreeable odour, and a bitterish, somewhat acrid taste. By time and exposure it becomes thicker and more yellow, and finally solid. It is usually brought into market in bottles, and is kept in the shops under the name of *Canada balsam* or *balsam of fir*. In Europe, it is sometimes called *balm of Gilead*, from its supposed resemblance to that celebrated medicine. The term *balsam*, as at present understood, is improperly applied to it; as it contains no benzoic nor cinnamic acid, and is in fact a true turpentine, consisting chiefly of resin and volatile oil. Bonastre obtained, from 100 parts of Canada turpentine, 18·6 parts of volatile oil, 40·0 of resin easily dissolved by alcohol, 33·4 of sub-resin of difficult solubility in that fluid, 4·0 of caoutchouc similar to sub-resin, and 4·9 of bitter extractive and salts, besides traces of acetic acid. There is reason to believe that *Strasburg turpentine* is sometimes sold for it in the shops.

4. Venice Turpentine.

Térébenthine de mélèze, Térébenthine de Venise, *Fr.;* Venetianischer Terpentin, *Germ.;* Trementina di Venezia, *Ital.;* Trementina de Venecia, *Span.*

This turpentine was named from the circumstance that it was formerly an extensive article of Venetian commerce. It is procured in Switzerland, and the French province of Dauphiny, from the *Larix Europæa* or larch, which grows abundantly upon the Alps and the Jura mountains. The peasants bore holes into the trunk about two feet from the ground, and conduct the juice by means of wooden gutters into small tubs, placed at a convenient distance. It is afterwards purified by filtration through a leather sieve. Genuine Venice turpentine is a viscid liquid, of the consistence of honey, flowing with difficulty, cloudy or imperfectly transparent, yellowish or slightly greenish, of a strong not disagreeable odour, and a warm, bitterish, and acrid taste. It does not readily concrete on exposure, is not solidified by one-sixteenth of magnesia, and is entirely soluble in alcohol. (Guibourt, *Journ. de Pharm.*, xxv. 500.) What is sold under the name of Venice turpentine, in our shops, is usually quite brown, and is said to be a factitious substance, prepared by dissolving rosin in oil of turpentine. Dr. A. T. Thomson states that much of the Venice turpentine of the shops of London is obtained from America. It is probably the same preparation as that which passes under the name in this country.

5. Chian Turpentine.

Térébenthine de Chio, *Fr.;* Cyprischer Terpentin, *Germ.;* Trementina Cipria, *Ital.*

This variety of turpentine is collected chiefly in the island of Chio or Scio, by incisions made during the summer in the bark of *Pistacia Terebinthus*. The juice, flowing from the wounds, falls upon smooth stones placed at the foot of the tree, from which it is scraped with small sticks, and allowed to drop into bottles. The annual product of each tree is very small; and the turpentine, therefore, commands a high price even in the place where it is procured. Very little of it reaches this country. It is said to be frequently adulterated with the other turpentines. It is a thick, tenacious liquid, of a greenish-yellow colour, a peculiar penetrating odour more agreeable than that of the other substances of the same class, and a mild taste without bitterness or acrimony. It leaves a glutinous residue when treated with strong alcohol. (*Guibourt.*) On exposure to the air it speedily thickens, and ultimately becomes concrete and hard, in consequence of the loss of its volatile oil.

Besides the turpentines mentioned, various others are noticed in books on materia medica, though not found in the shops of this country. There are the *Strasburg turpentine*, much used in France, and obtained from the *Abies Picea* (*Abies pectinata* of De Candolle), or European silver fir, which grows on the mountains of Switzerland and Germany, and bears a close resemblance, as well in its appearance as its product, to *Abies balsamea* of Canada; the *Damarra turpentine*, which speedily concretes into a very hard resin, and is derived from the *Pinus Damarra* of Lambert, the *Agathis Damarra* of Richard, growing in

the East India Islands; the *cowrie* or *cowdie* resin, procured by incision from another species of Damarra (*D. australis*) in New Zealand; and the *Dombeya turpentine*, a glutinous, milky-looking fluid, of a strong odour and taste, derived from *Dombeya excelsa*, the *Araucaria Dombeyi* of Richard, which inhabits Chili, and is said to be identical with the Norfolk Island pine. These, with one or two other turpentines scarcely known, or having a doubtful claim to the title, are all that belong properly to this class of vegetable products.*

General Properties. The turpentines resemble each other in odour and taste, though distinguished by shades of difference. Liquid at first, they become thick and gradually solid by exposure, in consequence partly of the volatilization, partly of the oxidation of their essential oil. They are rendered more liquid or softened by heat, and at a high temperature take fire, burning with a white flame and much smoke. Water extracts only a minute proportion of their volatile oil. They are almost wholly soluble in alcohol and ether, and readily unite with the fixed oils. They yield by distillation a volatile oil, called *oil of turpentine;* the residue consisting exclusively of resin. (See *Oleum Terebinthinæ* and *Resina.*) A minute proportion of succinic or acetic acid passes over with the oil. From the experiments of M. Faure, of Bordeaux, it appears that some of the liquid turpentines, like copaiba, may be solidified by the addition of magnesia. (*Journ. de Chim. Méd.*, 1830, p. 94.) According to M. Thierry, the same result is obtained by the addition of one part of hydrate of lime to thirty-two parts of common European turpentine. (*Journ. de Pharm.*, 3e sér., i. 315.)

Medical Properties and Uses. The effects of the turpentines upon the system are dependent entirely on their volatile oil. They are stimulant, diuretic, anthelmintic, and in large doses laxative. When taken internally, or applied to the skin, they communicate a violet odour to the urine, and, if continued for some time, produce an irritation of the mucous membrane of the urinary passages, amounting frequently to strangury. The last effect is less apt to be experienced when they operate upon the bowels. Externally applied they act as rubefacients. Their medical virtues were known to the ancients. At present they are less used than formerly, having been superseded by their volatile oil. They are, however, occasionally prescribed in leucorrhœa, gleet, and other chronic diseases of the urinary passages; in piles and chronic inflammation or ulceration of the bowels; in chronic catarrhal affections; and in various forms of rheumatism, especially sciatica and lumbago. The white turpentine is usually employed in this country. They may be given in the shape of pill made with powdered liquorice root; in emulsion with gum arabic or yelk of egg, loaf sugar, and water; or in electuary formed with sugar or honey. Their dose is from a scruple to a drachm. In the quantity of half an ounce or an ounce, triturated with the yelk of an egg, and mixed with half a pint of mucilaginous liquid, they form an excellent injection in cases of ascarides, and of constipation with flatulence.

The vapour of turpentine, employed as a vapour-bath, has been highly recommended in obstinate chronic rheumatism. According to M. A. Chevandier, it is borne well for about twenty-five minutes, at a temperature of from 140° to 160° F., producing acceleration of the pulse, and copious sweating, sometimes accompanied with a confluent eruption. (*Arch. Gén.*, 4e sér., xxviii. 80.)

Off. Prep. of Turpentine. Ceratum Resinæ Compositum, *U. S.;* Emplastrum Galbani Comp., *U. S.;* Emplastrum Picis, *Br. Of Canada Turpentine.* **Charta Epispastica**, *Br.;* **Collodium Flexile**, *Br.* W.

* The product of *Abies picea*, referred to in the text as *Strasburg turpentine*, is, according to Guibourt, nearly as liquid as olive oil, at first turbid and whitish, but becoming by filtration or long standing transparent and almost colourless, of an agreeable odour, analogous to that of the citron, and of a taste moderately acrid and bitter. It dries quickly in the air, is solidified by a sixteenth of magnesia, and is not entirely soluble in alcohol. It is procured by incisions into the vesicles which form upon the surface of the tree, beneath the outer bark. Guibourt states that this is the true *Venice turpentine*, while that described in the text, and generally recognised by authors as Venice turpentine, is in fact the *Strasburg.* (*Journ. de Pharm.*, xxv. 487.)

TESTA. *U. S.*

Oyster-shell.

The shell of Ostrea edulis. *U. S.*

Ecailles des huitres, *Fr.;* Austerschalen, *Germ.;* Gusci della ostriche, *Ital.;* Cascaras, *Span.*

The common oyster is the *Ostrea edulis* of naturalists, an animal belonging to the division *Mollusca*, class *Acephala*, order *Testacea*, and family *Ostracea*. It is found in many parts of the world, and is particularly abundant on our own coast, and in the bays of our large rivers. It consists of a soft pulpy portion, comprising the vital organs of the animal enclosed in a hard bivalve shell, of the nature of mother-of-pearl. The flesh of the oyster forms a very digestible and nutritious article of food, particularly suited to convalescents; but the shell only is officinal.

Properties. Oyster-shells are too familiarly known to require description They are made up, like other mother-of-pearl shells, of alternate layers of earthy and animal matter, the latter being of the nature of coagulated albumen. According to the analysis of Bucholz and Brandes, their constituents are carbonate of lime 98·6, phosphate of lime 1·2, animal matter 0·5, alumina (accidental) 0·2 = 100·5. Thus it appears that the animal matter is present in but small amount. When calcined or burnt, the animal matter and carbonic acid are dissipated, and the shells are converted into a species of lime, called *oyster-shell lime.*

Some credit has recently been claimed, on the basis of one or two favourable cases, for the efficiency of oyster-shell, taken internally and applied locally, in the treatment of cancer. The shells having been baked for three nights in a slow oven, the white part is scraped out, powdered, and taken in the quantity that will lie on an English shilling piece, once or twice daily, in a little warm water or tea; the treatment to be suspended for a day or two if it disturb the system. The powder may be applied, made into an ointment with cream, lard, or butter, without salt. The treatment must be continued three or four months before its effects are to be expected. The theory of the operation is that the blood-vessels supplying the tumour undergo calcareous degeneration. (Dr. P. Hood, *Lancet*, Oct. 1867, p. 484.)

Pharmaceutical Uses. Oyster-shells must be reduced to an impalpable powder, before they are fit for medical use. Thus prepared they form *Testa Præparata*, under which head their medicinal properties are noticed.

TORMENTILLA. *U. S. Secondary.*

Tormentil.

The root of Potentilla Tormentilla. *U. S.*

Tormentille, *Fr.;* Tormentillwurzel, *Germ.;* Tormentilla, *Ital.;* Tormentila, *Span.*

POTENTILLA. *Sex. Syst.* Icosandria Polygynia. — *Nat. Ord.* Rosaceæ.

Gen. Ch. Calyx with a concave tube, a four or five-cleft limb, and four or five bractlets. *Petals* four or five. *Stamens* numerous. *Carpels* numerous, with a lateral style, on a procumbent, persistent, capitate, juiceless receptacle. *Seed* appended. Herbs or undershrubs, with compound leaves, stipules adnate to the petiole, and white, yellow, rarely red flowers. (*De Candolle.*)

Potentilla Tormentilla. Sibthorp, *Fl. Ox.* 162; Lindley, *Flor. Med.* 225. — *Tormentilla erecta.* Willd. *Sp. Plant.* ii. 1112; Woodv. *Med. Bot.* p. 503, t. 181. — *T. officinalis.* Smith, *Flor. Brit* The tormentil, or *septfoil*, is a small perennial plant, very common throughout Europe. The stems, which rise about six or eight inches in height from a woody root, are slender, more or less erect, branching towards the top, and furnished with sessile leaves, which on the stalk usually consist of seven, on the branches of five, digitate, elliptical, villous, deeply serrated leaflets, three larger than the others. The flowers are small,

yellow, and solitary upon axillary peduncles. All parts of the plant are astringent, especially the root, which is the part employed. It is gathered in spring.

Properties. The root of tormentil is cylindrical or roundish, rather larger above than at the lower extremity, an inch or two in length, about as thick as the finger, knotty, sometimes contorted, brown or blackish externally, and reddish within. It has a slight aromatic odour, and a very astringent taste. Tannin is an abundant constituent. There is also a red colouring principle, soluble in alcohol, but insoluble in water. Besides these ingredients Meissner found resin, cerin myricin, gummy extractive, gum, extractive, lignin, water, and a trace of volatile oil. Tormentil has recently been chemically examined by Rembold, who obtained tormentilla red by boiling the tannin of the root with sulphuric acid. It has the same composition as rhatany red. He also obtained kinovic acid from the root by boiling it with milk of lime, adding muriatic acid to the decoction, boiling the precipitate with solution of baryta, decomposing again by muriatic acid, dissolving the precipitate in alcohol, decolorizing with animal charcoal, filtering, concentrating, and crystallizing. (*Am. Journ. of Pharm.*, July, 1868, p. 311; from *Ann. der Chem. und Pharm.*, cxliv. 5.) The root is said to be used for tanning leather in the Orkneys and Western Islands of Scotland, and for staining leather red by the Laplanders. It yields its virtues to boiling water.

Medical Properties and Uses. Tormentil is a simple and powerful astringent, applicable to all cases of disease in which this class of medicines is indicated. We seldom, however, employ it in this country, having indigenous plants of equal virtue. It may be given in substance, decoction, or extract. The dose of the powder is from thirty grains to a drachm. W.

TOXICODENDRON. *U. S. Secondary.*

Poison-oak.

The leaves of Rhus Toxicodendron. *U. S.*

Sumach vénéneux, *Fr.;* Gift-Sumach, *Germ.;* Albero del veleno, *Ital.*

RHUS. See RHUS GLABRUM.

Admitting, as appears generally to be done at present, that *Rhus Toxicodendron* and *Rhus radicans* of Linnæus are mere varieties of the same plant, there are four indigenous species of Rhus which possess poisonous properties —the one above mentioned; *R. vernix*, commonly known by the name of *swamp sumach* or *poison sumach;* *R. pumilum* of the Southern States; and *R. diversiloba* of California, where it is known by the Spanish name of *hiedra.* Though the first only is designated in the Pharmacopœia, we shall briefly describe the four; as their medical effects are probably similar, and their operation upon the system such that the plants should be known to every practitioner.

1. *Rhus radicans.* Willd. *Sp. Plant.* i. 1481; Bigelow, *Am. Med. Bot.* iii. 17. —*R. Toxicodendron.* Pursh, *Fl. Am. Sept.* p. 205. Though Elliott and Nuttall consider *R. radicans* and *R. Toxicodendron* as distinct species, the weight of botanical authority is on the other side; and Bigelow declares that he has "frequently observed individual shoots from the same stock, having the characters of both varieties." The difference, however, in their appearance is sufficiently striking to have led to the adoption of different common names; R. radicans being usually called *poison vine*, and R. Toxicodendron, *poison-oak.* The former has a climbing stem, rising to a great height upon trees, rocks, and other objects, to which it adheres by strong rooting fibres, which it throws out from its sides. The leaves, which stand upon long footstalks, are ternate, with broad-ovate or rhomboidal, acute leaflets, smooth and shining on both sides, sometimes slightly hairy on the veins beneath, entire, or irregularly lobed and toothed. The flowers are small, greenish-white, dicœcious, and grow in lateral, usually axillary panicles, or compound racemes. The male flowers have five stamens, and the rudiments of a style; the female, which are of only half the size, and on a different plant, have abortive stamens, and a short erect style, standing on a roundish germ, and terminating in three stigmas. The fruit consists of roundish, pale-green or whitish berries.

R. Toxicodendron, or poison-oak, has the form of a shrub from one to three feet high, with leaflets angularly indented, and pubescent beneath. But this character of the foliage is probably not constant; and the stunted growth may be owing to peculiarities of situation. Dr. Bigelow states that the young plants of R. radicans do not put forth rooting fibres until several years old, and are influenced in this respect by the contiguity of supporting objects.

This species of Rhus grows in woods, fields, and along fences from Canada to Georgia. It flowers in June and July. When wounded it emits a milky juice, which becomes black on exposure to the air, and leaves upon linen or other cloth a stain, which cannot afterwards be removed by washing with soap and water, or by alcohol either hot or cold, but deepens by age. It has been proposed as an indelible ink. Ether dissolves it.

The juice applied to the skin frequently produces inflammation and vesication; and the same poisonous property is possessed by a volatile principle which escapes from the plant itself, and produces in certain persons, when they come into its vicinity, an exceedingly troublesome erysipelatoid affection, particularly of the face. Itching, redness, a sense of burning, tumefaction, vesication, and ultimate desquamation, are some of the attendants of this poisonous action. The swelling of the face is sometimes so great as almost entirely to obliterate the features. The effects are experienced soon after exposure, and usually begin to decline within a week. A light, cooling regimen, with saline purgatives, and the local use of cold lead-water, are the best remedies. Dr. A. Livezey, of Lumberville, Penn., strongly recommends a saturated tincture of lobelia as a local application in this affection. He applies it by means of linen or muslin cloths, and believes that it arrests the inflammation. (*Boston Med. and Surg. Journ.*, lv. 262.) According to Prof. Procter, who is himself very susceptible to this poison, a weak alkaline solution, applied immediately after exposure, seldom fails to prevent the effects; and, after the vesicles are formed, he has found that Monsel's solution (*Liq. Ferri Subsulphatis*, U. S.), introduced by a pointed instrument into the vesicle, renders it abortive. (*Am. Journ. of Pharm.*, Nov. 1863, p. 506.) All persons are not equally liable to the affection, and the great majority are wholly insusceptible of it from any ordinary exposure.

2. *Rhus vernix.* Willd. *Sp. Plant.* i. 1479; Bigelow, *Am. Med. Bot.* i. 96.— *R. venenata.* Gray, *Manual, &c.*, p. 76. *Swamp sumach* is a beautiful shrub or small tree, usually ten or fifteen feet high, but sometimes thirty feet. The bark of the trunk is dark-gray, of the branches lighter, of the extreme twigs and petioles beautifully red. The leaves are pinnate, with four or five pairs of opposite leaflets, and an odd terminal one. These are oblong or oval, entire or slightly sinuated, acuminate, smooth, and, except the one at the end, nearly sessile. The flowers, as in the preceding species, are diœcious. They are very small, greenish, and in loose axillary panicles. The berries are small, roundish, and greenish-white. The tree grows in swamps and low grounds, from Canada to Carolina, and flowers in June and July. It is thought to be identical with a species of Rhus which grows in Japan, and furnishes a fine black varnish, much used in that country. Dr. Bigelow found that the opaque whitish juice which exudes from our native plant when wounded, and which becomes permanently black on exposure, may be made to afford a brilliant, glossy, durable varnish, by boiling it sufficiently before applying it.

Rhus vernix produces, much more powerfully than *R. radicans*, the poisonous effects already described. Persons coming within its influence are more apt to be affected with the poison, and generally suffer more severely. The whole body is sometimes enormously swollen, and the patient for many days scarcely able to move; but the complaint almost always spontaneously subsides without destroying life. As in the former instance, the susceptibility to the influence of the poison is exceedingly various, and some persons handle the plant with perfect impunity.

3. *Rhus pumilum.* Michaux, *Flor. Americ.* i. 182. This is a southern species, growing in upper Carolina, and not more than a foot in height. It is characterized by its pubescent branches and petioles; its pinnate leaves, with many pairs

of oval, nearly acuminate, incised-dentate leaflets, downy beneath; and by its silky fruit. According to Pursh, it is the most poisonous of the genus.

4. *Rhus diversiloba.* Torrey & Gray, *Flor. of North Am.* i. 218.—*R. lobata.* Hooker, *Flor. Bor. Am.* i. 127, t. 46. This species approaches nearly the R Toxicodendron. It has a somewhat climbing stem, with short, leafy branches. The leaves have three or rarely five leaflets, which are very obtuse, in the female plant slightly, in the male rather deeply pinnately lobed, the lobes being very obtuse, and the incisions acute. The flowers are in axillary, racemose panicles often shorter than the petioles, and the fruit white, somewhat pubescent, and subglobose. The leaves in the male and female plant are so different that they might readily be mistaken for different species. (*Torrey & Gray.*) Though generally a shrub, the plant sometimes climbs over large trees, and has a stem six inches in diameter. In a communication to the *American Journal of Pharmacy* (Sept. 1860, p. 412), the poisonous effects of this plant are described by Dr. C. A. Canfield, who found an invariable antidote to its effects in another California plant, *Grindelia hirsutula,* which is applied to the part either simply bruised, or in the form of strong decoction.

It is probable that all parts of Rhus radicans (R. Toxicodendron) are active; but the leaves only are directed in the Pharmacopœia, under the title of Toxicodendron. These are inodorous, have a mawkish acrid taste, and yield their virtues to water. Analyzed by Dr. Joseph Khittel, the leaves yielded tannic acid of the variety which gives greenish precipitates with salts of iron, chlorophyll, wax, fixed oil, resin, sugar, albumen, gum, pectin, starch, oxalic acid, a peculiar neuter substance, and a *volatile alkaloid,* on which the poisonous properties of the plant depend. To obtain this alkaloid, a concentrated infusion of the leaves was distilled with potassa, the distillate saturated with sulphuric acid and evaporated, a mixture of alcohol and ether then added which left sulphate of ammonia behind, the solution distilled with caustic potassa, and an alkaline distillate obtained, which contained the alkaloid in question. But it does not appear to have been further isolated, and no proofs are given of its poisonous properties. (See *Am. Journ. of Pharm.,* Nov. 1858, p. 544.) The results obtained by Dr. Khittel have been subsequently entirely discredited by the experiments of Prof. John M. Maisch, of Philadelphia, who not only failed to detect a volatile alkaloid in the distillate, but found in it a volatile acid, and succeeded in determining this acid to have properties which, though analogous to those of formic and acetic acids, are quite distinct, and entitle it to be regarded as a newly discovered principle. Prof. Maisch gave it the name of *toxicodendric acid,* to which it would seem to be entitled; as there is no doubt that it is the active poisonous principle of the plant, so far, at least, as the irritant effect on the skin is concerned; Prof. Maisch, as well as others exposed to the vapours of the acid, having suffered a copious characteristic eruption of eczematous vesicles on the hand, wrist, and forearm. He employed as remedies against the eruption, solutions of acetate of lead and permanganate of potassa, and ammonia; the last with most satisfactory results. To obtain the acid, the leaves were bruised with 6 per cent. of slaked lime, and after maceration with water were expressed. The expressed liquid, having been mixed with an excess of sulphuric acid, was distilled, and the vapours were condensed, partly by themselves, so as to obtain the pure acid, and partly in water containing carbonate of baryta in suspension, so as to get the toxicodendrate of baryta. The acid solution thus obtained is colourless, strongly reddens litmus paper, and neutralizes bases. For further particulars, the reader is referred to the paper of Prof. Maisch in the *Proceedings of the American Pharmaceutical Association,* A. D. 1865; also in the *Am. Journ. of Pharm.* (Jan. 1866, p. 4).

Medical Properties and Uses. The leaves of Rhus Toxicodendron appear to be stimulant and narcotic, producing when swallowed more or less irritation of the stomach and bowels, and promoting the secretory function of the skin and kidneys. Orfila found them to act in the manner of the acrid poisons, and to produce a stupefying effect upon the nervous system. They were successfully

used by Du Fresnoy, in France, in the cure of obstinate cutaneous diseases. Dr. Anderson, of Hull, in England, effected cures with the medicine in several cases of palsy. A sense of heat and pricking, with irregular twitchings, was excited by it in the affected parts. Dr. Horsfield and other physicians of this country have used it in consumption and dropsy, but with little success. The remedy has been found efficacious in nocturnal incontinence.

The dose of the leaves recommended by Dr. Anderson was half a grain or a grain three times a day; but this is much too small. Dr. Duncan gave them in larger doses, with little other than a laxative effect. Dr. Horsfield administered a teacupful of the strong infusion without disadvantage. In France, the extract is recommended in doses of fifteen or twenty grains, repeated two or three times a day, and gradually increased to one or two drachms. Some of Du Fresnoy's patients took an ounce without effect. The probability is, that the active principle is volatile, and that the extract is less efficient than the leaves themselves. The risk of experiencing the poisonous effects of the plant upon the system, will probably prevent its extensive employment as a remedy, unless it should prove much more useful than the trials hitherto made give us reason to expect.

Two instances of poisoning by the internal use of the plant have been recently recorded; one from the eating of the fruit by children, reported in the *Am. Journ. of Med. Sci.* (April, 1866, p. 560) by Dr. J. W. Moorman, of Hardinsburg, Ky.; the other from drinking an infusion of the root, in mistake for sassafras root, also by children, reported by Dr. James Stokes, of Philadelphia, in the *Med. and Surg. Reporter* (Nov. 2, 1867, p. 353). In the first instance, in which nearly a pint of the fruit had been eaten by two children, one six and the other eight years old, after a few hours from the swallowing of the poison, drowsiness and stupor came on, soon followed by vomiting, first of the partially digested fruit, and afterwards of a thick viscid fluid of a wine colour. This was succeeded by convulsive movements of different parts of the body, with slight delirium. The pupils were dilated. The respiration was hurried, the pulse at first full and strong, but afterwards slow, small, frequent, and feeble. The vomiting was promoted by the use of warm water; and carbonate of soda was then given freely in solution as an antidote. Both children recovered. In the cases in which an infusion of the root was taken, one, a boy of twelve years, was covered with an eruption over the body, which was especially vesicular in the face, with a dry, hoarse cough, soreness of throat, burning sensations extending to the stomach, high fever, a coated tongue, scanty, high-coloured, and irritating urine, nervous twitchings, and occasional wandering. The diagnosis, somewhat difficult at first, became easy on the occurrence of two other cases, girls respectively of fifteen and seventeen, who with their brother, the boy just mentioned, had been drinking of the infusion referred to. They were treated by saline cathartics in small doses, the local use of lead-water, and an improved diet, and all recovered, with general desquamation. W.

TRAGACANTHA. *U. S., Br.*

Tragacanth.

The concrete juice of Astragalus verus, and of other species of Astragalus. *U. S.* A gummy exudation from the stem of Astragalus verus, and possibly other species. *Br.*

Gomme Adraganthe, *Fr.;* Tragant, *Germ.;* Dragante, *Ital.;* Gomo tragacanto, *Span.*

Astragalus. *Sex. Syst.* Diadelphia Decandria. — *Nat. Ord.* Fabaceæ or Leguminosæ.

Gen. Ch. Legume two-celled, more or less gibbous, with the lower suture turned inwards. *Carina* blunt. *Loudon's Encyc. of Plants.*

Numerous species belonging to this genus yield a gummy matter having the properties of tragacanth. The drug known in commerce by that name was at first erroneously supposed to be obtained from *A. Tragacantha* of Linnæus (*A. massiliensis* of Lamarck), which grows in the south of Europe and north of

Africa, and is now said to yield no gum. It was afterwards ascribed, on the authority of Tournefort, to a species (*A. Creticus* of Lamarck) which grows in Crete and Ionia, and on that of Olivier, to *A. verus*, which inhabits Asia Minor, Armenia, and Northern Persia. Labillardière described a species by the name of *A. gummifer*, which he found growing on Mount Libanus in Syria, and from which tragacanth exudes, though not that of commerce. Sieber denies that any one of these species yields the officinal tragacanth, which he ascribes to *A. aristatus*, growing in Anatolia, especially upon Mount Ida, where the gum is most abundantly collected. This plant, however, is not the *A. aristatus* of Villars, which, according to Sibthorp, furnishes tragacanth in Greece. (*Merat and De Lens.*) Professor Lindley received two specimens of plants, said to be those which furnish tragacanth in Turkistan, one of which proved to be *A. gummifer* of Labillardière, which was said to yield a white variety, and the other a new species, which he called *A. strobiliferus*, and which was said to yield a red and inferior product. The fact seems to be, that the commercial drug is collected from various sources; and it is affirmed that all the species of Astragalus with thorny petioles are capable of producing it. These form a natural group, and so closely resemble each other that botanists have found some difficulty in distinguishing them. They are very abundant on the mountains of Asia Minor, and, according to information recently received by M. J. Leon Soubeiran from M. Balansa, a scientific traveller who derived his knowledge from personal observation, the gum-producing species are closely analogous to the *A. Creticus* of Lamarck. It is in the chain of Anti-Taurus that the gum is chiefly collected. Transverse incisions are made, near the base of the stem, into the medullary part, which alone yields juice. This exudes very slowly, flowing at night, and ceasing during the day; and two weeks usually elapse before the pieces are large enough for collection. The shape of the pieces is influenced by the rapidity of the exudation, and the lines on their surface indicate the daily concretion. (*Journ. de Pharm.*, Feb. 1856, p. 117, and Feb. 1857, p. 149) As *A. verus* is designated in the Pharmacopœias of the United States and Great Britain, we shall briefly describe it.

Astragalus verus. Olivier, *Voy. dans l' Empire Ottoman*, p. 342, pl. 44. This is a small shrub, not more than two or three feet high, with a stem an inch in thickness,and numerous very closely crowded branches,covered with imbricated scales, and spines which are the remains of former petioles. The leaves, which are little more than half an inch long, consist of several pairs of opposite, villous, stiff, pointed leaflets, with a midrib terminating in a sharp yellowish point. The flowers are papilionaceous, small, yellow, axillary, aggregate, and furnished with cottony bractes. This species yields the gum collected in Persia, and thence transmitted southward to India through Bagdad and Bassora,northward to Russia, and westward to Aleppo. The juice is said to exude spontaneously during the summer from the stems and branches, hardening as it exudes.

Properties. Tragacanth is either in flaky, leaf-like pieces, irregularly oblong or roundish, or in tortuous vermicular filaments, rounded or flattened, rolled up or extended, of a whitish, yellowish-white, or slightly reddish colour, somewhat translucent, and resembling horn in appearance. It is hard and more or less fragile, but difficult of pulverization, unless exposed to a freezing temperature, or thoroughly dried, and powdered in a heated mortar. The powder is very fine and white. Tragacanth has no smell, and very little taste. Its sp. gr. is 1·384. Introduced into water, it absorbs a certain proportion of that liquid, swells very much, and forms a soft adhesive paste, but does not dissolve. If agitated with an additional quantity of water, this paste forms a uniform mixture; but in the course of one or two days the greater part separates, and is deposited, leaving a portion dissolved in the supernatant fluid. Tragacanth is wholly insoluble in alcohol. It appears to be composed of two different constituents, one soluble in water and resembling gum arabic, the other swelling in water, but not dissolving. The former is said to differ from gum arabic in affording no precipitate with silicate of potassa or sesquichloride of iron. (*Pereira's Materia Medica*) The latter, which, according to Bucholz, constitutes 43 per cent. of tragacanth,

is ranked by some among the peculiar proximate principles with the title of *tragacanthin*. It is probably identical with *bassorin*. It has the property of becoming blue with iodine, which is not the case with bassorin; but this property is ascribed to the presence of a small quantity of insoluble starch. According to M. Guérin, 100 parts of tragacanth contain 53·3 parts of arabin or pure gum, 33·1 of bassorin and insoluble starch, and 11·1 of water, and yield when burned 2·5 parts of ashes. To separate the soluble entirely from the insoluble part, requires agitation with separate portions of water, which are to be decanted and filtered; and the process is to be continued till water ceases to dissolve anything. Examined by Dr. Kützing, by means of the microscope, tragacanth was found to consist of organized cells. (See *Am. Journ. of Pharm.*, xxv. 37.) In conformity with this statement is the remarkable fact, developed by the researches of Hugo von Mohl, that tragacanth is not a secretion of the plant, but the result of the transformation of the cells of the pith, and those of the medullary rays which run across the ligneous part of the stem. (*Ibid.*, xxxi. 243.)

It is stated by Mr. S. H. Maltass that tragacanth is adulterated, in the Levant, with worthless gums brought from Armenia and Caramania, which, as they are originally of a dark colour, and destitute of the flaky form of the genuine gum, are broken into small fragments, and whitened by means of carbonate of lead, before being mixed with the tragacanth. Mr. Hanbury states, in confirmation of this information, that he has detected lead in the *small tragacanth* imported into London. (*Pharm. Journ.*, xv. 20.)

Medical Properties and Uses. Tragacanth is demulcent, but, on account of its difficult solubility, is not often given internally. The great viscidity which it imparts to water, renders it useful for the suspension of heavy insoluble powders; and it is also employed in pharmacy to impart consistence to troches, for which it answers better than gum arabic.

TRIOSTEUM. *U. S. Secondary.*

Fever-root.

The root of Triosteum perfoliatum. *U. S.*

Triosteum. *Sex. Syst.* Pentandria Monogynia.—*Nat. Ord.* Caprifoliaceæ.

Gen. Ch. Calyx five-cleft, persistent, nearly the length of the corolla; segments linear, acute. *Corolla* tubular, five-lobed, sub-equal; base nectariferous gibbous. *Stigma* somewhat five-lobed, capitate. Berry three-celled, three-seeded, crowned with the calyx. *Nuttall.*

Triosteum perfoliatum. Willd. *Sp. Plant.* i. 990; Bigelow, *Am. Med. Bot.* i. 90; Barton, *Med. Bot.* i. 59. This plant is indigenous and perennial. Several stems usually rise from the same root. They are simple, erect, round, hairy, fistulous, herbaceous, and from one to four feet high. The leaves are opposite, large, mostly connate, oval, acuminate, entire, abruptly narrowed at the base, and pubescent on their under surface. The flowers are of a dull-purple colour, axillary, sessile, rarely solitary, sometimes in pairs, generally in triplets or five together in the form of whorls. The germ is inferior, and the style projects beyond the corolla, into the tube of which the stamens are inserted. The berry is oval and of a deep-orange colour, and contains three hard, bony seeds.

Fever-root, fever-wort, or *wild ipecac*, as this plant is variously called, though not very abundant, is found in most parts of the United States, preferring a limestone soil and shady situations. Its flowers appear in June. The whole plant is bitter; but the root is most active, and is the only officinal part.

It is horizontal, long, about three-quarters of an inch in diameter, thicker and tuberculated near the origin of the stem, of a yellowish or brownish colour externally, whitish within, and furnished with fibres which may be considered as branches of the main root. When dry it is brittle and easily pulverized. It

has a sickening odour, and a bitter, nauseous taste. Both water and alcohol take up its active properties, which are retained in the extract.

Medical Properties and Uses. Fever-root is cathartic, and in large doses emetic. The late Professor Barton observed it also to produce a diuretic effect. The bark of the root is the part which has been usually employed. In the quantity of twenty or thirty grains it ordinarily acts upon the bowels; and may be given alone or in combination with calomel at the commencement of fevers. The extract may be given in half the dose. W.

ULMI CORTEX. *Br.*

Elm bark.

The dried inner bark of Ulmus campestris, Broad-leaved Elm. *Br.*

Ecorce d'orme, *Fr.;* Ulmenrinde, *Germ.;* Scorza del olma, *Ital.;* Corteza de olmo, *Span.*

Ulmus. *Sex. Syst.* Pentandria Digynia. — *Nat. Ord.* Ulmaceæ.

Gen. Ch. Calyx five-cleft. *Corolla* none. *Capsule* (*samara*) compressed, membranaceous. *Willd.*

Ulmus campestris. Willd. *Sp. Plant.* i. 1324; Woodv. *Med. Bot.* p. 710, t. 242. This species of elm is characterized by its doubly serrate leaves, unequal at their base, by its nearly sessile, clustered, pentandrous flowers, and its smooth fruit. It is a large tree, with strong spreading branches, and a rough, cracked bark. It is a native of Europe, where the wood is highly esteemed in the arts.

The inner bark of its young branches, which is the officinal portion, is thin, tough, brownish-yellow, inodorous, and of a mucilaginous, bitterish, and very slightly astringent taste. It imparts to water its taste and mucilaginous properties. Tincture of iodine indicates the presence of starch, and Davy found somewhat more than 2 per cent. of tannin. A vegetable principle called *ulmin* or *ulmic acid*, now believed to be a constituent of most barks, was first discovered in the matter which exudes from the bark of the European elm. It is a dark-brown, almost black substance, without smell or taste, insoluble in cold water, sparingly soluble in boiling water which it colours yellowish-brown, soluble in alcohol, and readily dissolved by alkaline solutions.

Medical Properties and Uses. The bark of the European elm is demulcent, and very feebly tonic and astringent, and is said also to be diuretic. It has been recommended in cutaneous affections of the leprous character. Dr. Sigmond speaks in strong terms of its efficacy in all the varieties of lepra, in lichenous eruptions, and tinea capitis, employed both internally and externally. (*Medico-bot. Trans.*, i. 169.) It is usually given in the form of decoction, and in chronic cases must be long continued to produce beneficial results.

ULMUS FULVA. *U.S.*

Slippery-elm Bark.

The inner bark of Ulmus fulva. *U. S.*

Ulmus. See ULMI CORTEX.

Ulmus fulva. Michaux, *Flor. Americ.* i. 172. — *Ulmus rubra.* F. Andrew Michaux, *N. Am. Sylv.* iii. 89. The *slippery elm*, called also *red elm*, is a lofty tree, rising fifty or sixty feet in height, with a stem fifteen or twenty inches in diameter. The bark of the trunk is brown, that of the branches rough and whitish. The leaves are oblong-ovate, acuminate, nearly equal at the base, unequally serrate, pubescent, and very rough on both sides, four or five inches in length by two or three in breadth, and supported on short footstalks. The buds, a fortnight before their development, are covered with a dense russet down. The flowers, which appear before the leaves, are sessile, and in clusters at the extremity of the young shoots. The bunches of flowers are surrounded by scales,

which are downy like the buds. The calyx also is downy. There is no corolla. The stamens are five, short, and of a pale-rose colour. The fruit is a membranaceous capsule or samara, enclosing in the middle one round seed, destitute of fringe.

This species of elm is indigenous, growing in all parts of the United States north of the Carolinas, but most abundantly west of the Alleghany mountains. It flourishes in open, elevated situations, and requires a firm, dry soil. From the *white elm* (*U. Americana*) it is distinguished by its rough branches, its larger, thicker, and rougher leaves, its downy buds, and the character of its flowers and seeds. Its period of flowering is in April. The inner bark is the part used, and is brought to the shops separated from the epidermis. Large quantities are collected in the Lower Peninsula of Michigan.

It is in long, nearly flat pieces, from one to two lines thick, of a fibrous texture, a tawny colour which is reddish on the inner surface, a peculiar sweetish, not unpleasant odour, and a highly mucilaginous taste when chewed. By grinding, it is reduced to a light, grayish fawn-coloured powder. It abounds in mucilaginous matter, which it readily imparts to water. The mucilage is precipitated by solutions of acetate and subacetate of lead, but not by alcohol.

Much of the bark brought into the market is of inferior quality, imparting comparatively little mucilage to water. It has the characteristic odour of the genuine bark, but is much less fibrous and more brittle, breaking abruptly when bent, instead of being capable, like the better kind, of being folded lengthwise without breaking. To what this inferiority is owing, whether to difference in the species or the age, or to circumstances in the growth of the tree producing it, we are unable to determine.

Dr. C. W. Wright, of Cincinnati, in a communication to the *Western Lancet*, states that slippery-elm bark has the property of preserving fatty substances from rancidity; a fact derived originally from the Indians, who prepared bears' fat by melting it with the bark, in the proportion of a drachm of the latter to a pound of the former, keeping them heated together for a few minutes, and then straining off the fat. Dr. Wright tried the same process with butter and lard, and found them to remain perfectly sweet for a long time. (*Am. Journ. of Pharm.*, xxiv. 180.)

Medical Properties and Uses. Slippery-elm bark is an excellent demulcent, applicable to all cases in which this class of medicines is employed. It is especially recommended in dysentery, diarrhœa, and diseases of the urinary passages. Like the bark of the common European elm, it has been employed in cutaneous eruptions; but neither in these, nor in any other complaints, does it probably exert any greater powers than such as belong to the demulcents generally. Its mucilage is nutritious; and we are told that it has proved sufficient for the support of life in the absence of other food. The instance of a soldier is mentioned, who lived for ten days in the woods on this bark and sassafras; and the Indians are said to resort to it for nutriment in extreme emergencies.

Dr. J. R. Dowler, of Beardstown, Ill., reports two cases of tape-worm, one in a child, the other an adult, in which the worm was discharged, as a consequence of chewing and swallowing the bark of the elm. (*Bost. Med. and Surg. Journ.*, March 16, 1865, p. 132.)

It is commonly used as a drink in the form of infusion. (See *Infusum Ulmi.*) The powder may be used stirred in hot water, with which it forms a mucilage, more or less thick according to the proportion added. The bark also serves as an emollient application in cases of external inflammation. For this purpose the powder may be formed into a poultice with hot water, or the bark itself may be applied, previously softened by boiling. Dr. McDowell, of Virginia, recommended slippery-elm bark for the dilatation of fistulas and strictures (see *Med. Examiner*, i. 244); subsequently Dr. H. R. Storer, of Boston, used it advantageously for dilating the os uteri (*Bost. Med. and Surg. Journ.*, liii. 300); and Dr. A. Abbe, of the same place, succeeded in curing with it a case of stricture of the rectum. (*Ibid.*, liv 349.)

VITIS. *Sex. Syst.* Pentandria Monogynia. — *Nat. Ord.* Vitaceæ.

Gen. Ch. Petals cohering at the apex, withering. *Berry* five-seeded, superior. *Willd.*

Vitis vinifera. Willd. *Sp. Plant.* i. 1180; Woodv. *Med. Bot.* p. 144, t. 57. The vine is too well known to require description. This particular species is distinguished by the character of its leaf, which is lobed, sinuated, and naked or downy. The leaves and tendrils are somewhat astringent, and were formerly used in diarrhœa, hemorrhages, and other morbid discharges. The juice which flows from the stem was also thought to be possessed of medicinal virtues, and the prejudice still lingers among the vulgar in some countries. The unripe fruit has a harsh sour taste, and yields by expression a very acid liquor, called *verjuice*, which was much esteemed by the ancients as a refreshing drink, when diluted with water. It contains malic and tartaric acids, and another called by some chemists *racemic acid*, by Berzelius *paratartaric acid*, from its resemblance to the tartaric, with which it agrees in composition, though differing from it in properties. The grape, when quite ripe, is among the most pleasant and grateful fruits brought upon the table, and is admirably adapted, by its refreshing properties, to febrile complaints. If largely taken, it proves diuretic and gently laxative. The ripe fruit differs from the unripe in containing more sugar and less acid, though never entirely destitute of the latter. The plant is supposed to have been derived originally from Asia; but it has been cultivated in Europe and Northern Africa from the remotest antiquity, and is now spread over all the temperate civilized regions of the globe. The fruit is exceedingly influenced by soil and climate, and the varieties which have resulted from culture or situation are innumerable. Those which yield the raisins of commerce are confined to the basin of the Mediterranean.

Raisins are prepared either by partially cutting the stalks of the bunches before the grapes are perfectly ripe, and allowing them to dry upon the vine, or by picking them in their mature state, and steeping them for a short time previously to desiccation in an alkaline ley. Those cured by the first method are most highly esteemed.*

* *Culture of Raisins.* The statement in the text in relation to the mode of drying grapes is allowed to remain, because made on what was deemed competent authority; but, in a journey through the raisin districts in the Southeast of Spain, in the spring of 1861, the author made frequent inquiries at Malaga and Valencia, and found no one who had heard of the plan of partially cutting the stalks of the bunches, and then allowing them to dry on the plant. The following is a brief account of the raisin culture near Malaga. The grape cultivated for drying is exclusively the Muscatel. The district appropriated to this purpose consists of red-earth lands, along the coast of the Mediterranean, extending for about 30 miles on each side of Malaga. The grounds planted with the vine are the shore plains and valleys, the smaller hills, and the lower declivities of the mountains. The vines are kept trimmed very low, and the earth between them loosened by the spade; the plough not being used. The grapes are ripe in August, when the bunches are cut off, and carefully dried in the sun, upon a hard level earthen floor, prepared for the purpose, which is protected by a shed when it rains. After one side of the bunch has become dry, the other is carefully turned to the sun. When dried, they are generally packed in wooden boxes, each containing about 25 lbs. The most valuable, called the *bloom raisins* from the preservation of the bloom unbroken on the surface, are packed in paper boxes, and sent, as the author was told, exclusively to the London market, where they are especially esteemed. About a million of boxes are sent annually to the United States, valued at two millions of dollars. The *Valencia raisin* is a different variety from the Malaga. The grape is thicker-skinned, and does not dry well unless with previous preparation. Hence, as soon as picked, they are dipped into a ley made from wood ashes, immediately removed, and then dried. The

Several varieties of raisins are known in commerce. The best of those brought to this country are the *Malaga raisins*, imported from Spain. They are large and fleshy, of a purplish-brown colour, and sweet agreeable taste. Those produced in Calabria are similar. The *Smyrna raisins* are also large, but of a yellowish-brown colour, slightly musky odour, and less agreeable flavour. They are originally brought from the coast of Syria. The *Corinthian raisins*, or *currants* as they are commonly called in this country, are small, bluish-black, of a fatty appearance, with a vinous odour, and a sweet, slightly tartish taste. Their name was derived from the city in the vicinity of which they were formerly cultivated. At present they are procured chiefly from Zante, Cephalonia, and the other Ionian Islands. In the older Pharmacopœias they are distinguished by the title of *uvæ passæ minores*.

Raisins contain a larger proportion of sugar than recent grapes. This principle, indeed, is often so abundant that it effloresces on the surface, or concretes in separate masses within the substance of the raisin. The *sugar of grapes* (*glucose*) differs from that of the cane; being less sweet, less soluble in cold water, and much less so in alcohol, and forming a syrup of less consistence.

Medical Properties and Uses. The chief medical use of raisins is to flavour demulcent beverages. Taken in substance they are gently laxative; but are also flatulent and difficult of digestion, and, when largely eaten, sometimes produce unpleasant effects, especially in children.

ARCTOSTAPHYLOS. *Sex. Syst.* Decandria Monogynia. — *Nat. Ord.* Ericaceæ.

Gen. Ch. Drupe with five distinct, one-seeded stones. *Corolla* urceolate, with a revolute limb. *Stamens* included. *Anthers* with two spurs at the back. (Lindley, *Med. and Œcon. Bot.* 106.)

Arctostaphylos Uva Ursi. Sprengel, *Syst.* ii. 287; Carson, *Illust. of Med. Bot.* i. 61, pl. 52. — *Arbutus Uva Ursi.* Willd. *Sp. Plant.* ii. 618; Bigelow, *Am. Med. Bot.* i. 66. The *uva ursi*, or *bearberry*, is a low evergreen shrub, with trailing stems, the young branches of which rise obliquely upwards for a few inches. The leaves are scattered, upon short petioles, from half an inch to an inch long, obovate, acute at the base, entire, with a rounded margin, thick, coriaceous, smooth, shining, deep-green on their upper surface, paler and covered with a network of veins beneath. The flowers, which stand on short reflexed peduncles, are in small clusters at the ends of the branches. The calyx is small, five-parted, reddish, and persistent. The corolla is ovate or urceolate, reddish-white, or white with a red lip, transparent at the base, contracted at the mouth, and divided at the margin into five short reflexed segments. The stamens are ten, with short filaments and bifid anthers; the germ round, with a style longer than the stamens, and a simple stigma. The fruit is a small, round, depressed, smooth, glossy, red berry, with an insipid mealy pulp, and five cohering seeds.

This humble but hardy shrub inhabits the northern latitudes of Europe, Asia, and America. It is also found in the lofty mountains of Southern Europe, as

alkali causes the skin to crack in minute fissures, and thus facilitates drying. The author was assured that the Valencia raisins are not sent to the United States, but exclusively to England, where they are used in puddings. The Malaga grape, imported in the fresh state into this country, is a different variety from the raisin grape, and cultivated higher on the mountains. (*Note to the twelfth edition.*)

the Pyrenees and the Alps; and, on the American continent, extends from Hudson's Bay as far southward as New Jersey, in some parts of which it grows in abundance. It prefers a barren soil, flourishing on gravelly hills, and elevated sandy plains. The leaves are the only part used in medicine. They are imported from Europe; but are also collected within our own limits; and the market of Philadelphia is supplied to a considerable extent from New Jersey. They should be gathered in autumn, and the green leaves only selected.

In Europe the uva ursi is often adulterated with the leaves of *Vaccinium Vitis Idæa*, which are wholly destitute of its peculiar properties, and may be distinguished by their rounder shape, their revolute edges which are sometimes slightly toothed, and the appearance of their under surface, which is dotted, instead of being reticulated like the genuine leaf. Leaves of the *Chimaphila umbellata* are sometimes found among the uva ursi as it exists in our markets. They may be readily detected by their greater length, their cuneiform-lanceolate shape, and their serrate edges.

Properties. Uva ursi is inodorous when fresh, but acquires a smell not unlike that of hay when dried and powdered. Its taste is bitterish, strongly astringent, and ultimately sweetish. It affords a light-brown, greenish-yellow powder. Water extracts its active principles, which are also soluble in officinal alcohol. Among its ingredients are tannic and gallic acids, bitter extractive, resin, gum, fatty matter, a volatile oil, and salts of potassa and lime. The tannic acid is so abundant that the leaves are used for tanning in Russia. Neither this principle nor gallic acid exists in the leaves of the *Vaccinium Vitis Idæa.*

A crystallizable principle was extracted from uva ursi by Mr. J. C. C. Hughes by the following process. An aqueous extract of the leaves was treated with strong alcohol, and submitted for twenty-four hours to the action of purified animal charcoal. The tincture was filtered and evaporated, and the residue redissolved in alcohol, and treated with animal charcoal as before. After filtration, the liquid was allowed to evaporate spontaneously, and yielded colourless, transparent, needle-shaped crystals, soluble in water, alcohol, ether, and dilute acids, insoluble in the fixed and volatile oils, neutral to test-paper, and combustible. The watery solution was precipitated by subacetate of lead and carbonate of potassa, but not by lime-water or tincture of chloride of iron. One grain of it acted as a powerful diuretic. Mr. Hughes proposed for this substance the name of *ursin.* (*Am. Journ. of Pharm.*, xix. 90.)

Kawalier obtained a crystalline substance, named *arbutin*, by precipitating the decoction with acetate of lead, filtering, treating the liquid with sulphuretted hydrogen, again filtering, evaporating to the consistence of syrup, and allowing the product to stand for several days. This gradually assumed the form of a crystalline jelly, which, being placed upon linen so as to allow the mother-liquor to drain off, and then pressed, yielded nearly colourless crystals, which were purified by solution in boiling water, and treatment with animal charcoal. Arbutin thus obtained is in long, acicular, colourless crystals, united in tufts, and of a bitter taste. It is soluble in water, alcohol, and ether, unchanged apparently by a heat of 212°, but fusible at a high temperature, without action on vegetable colours, and not precipitated by the salts of sesquioxide of iron, or by acetate or subacetate of lead. It is a glucoside, being resolvable by boiling with sulphuric acid into glucose and a peculiar substance named *arctuvine.* Its formula is $C_{32}H_{24}O_{21}$. (*Chem. Gaz.*, Feb. 15, 1853, p. 61.) Strecker, however, gives a different formula, $C_{24}H_{16}O_{14}+2HO$, and considers the arctuvine of Kawalier as identical with *hydrochinone* prepared by Wöhler from kinic acid. (*Ibid.*, Feb. 1, 1859, p. 48.)

Another crystallizable principle has been discovered by Trommsdorff, who calls it *ursone.* It appears to be of a resinous character, being tasteless and inodorous, insoluble in water, difficultly soluble in alcohol and ether, fusible, at a higher temperature volatilizable, and inflammable in the air. It is obtained by treating uva ursi with a very small quantity of ether by percolation, allowing the ether to evaporate, washing the crystalline extract with ether, and recrystallizing from alcohol. (See *Am. Journ. of Pharm.*, xxvii. 334.)

Medical Properties and Uses. Uva ursi is astringent and tonic, and is thought by some to have a specific direction to the urinary organs, for the complaints of which it is chiefly used. Others deny that it possesses a peculiar tendency of this kind, and ascribe its effects to its astringent and tonic action. It alters the colour of the urine, and its astringent principle has been detected in that secretion. It probably, therefore, exerts a direct influence on the kidneys and urinary passages. Though known to the ancients, it had passed into almost entire neglect, till its use was revived by De Haen about the middle of the last century. It has acquired some reputation as an antilithic, and has undoubtedly been serviceable in gravel, partly, perhaps, by a direct action on the kidneys, partly by giving tone to the digestive organs, and preventing the accumulation of principles calculated to produce a secretion or precipitation of calculous matter. In chronic nephritis it is also a popular remedy, and is particularly recommended when there is reason to conjecture the existence of ulceration in the kidneys, bladder, or urinary passages. Diabetes, catarrh of the bladder, incontinence of urine, gleet, leucorrhœa, and menorrhagia are also among the diseases in which it has occasionally proved serviceable; and testimony is not wanting to its beneficial effects in phthisis pulmonalis. Dr. E. G. Harris, of Fayette, Alabama, believes it to have the property of promoting uterine contraction, and has employed it with supposed advantage as a substitute for ergot in tedious labours. (See *Med. Exam.*, N. S., ix. 727.) The dose of the powder is from a scruple to a drachm, to be repeated three or four times a day; but the decoction or fluid extract is usually preferred. (See *Part* II.)

Valeriana officinalis. Willd. *Sp. Plant.* i. 177; Woodv. *Med. Bot.* p. 77, t. 32. The *officinal*, or *great wild valerian*, is a large handsome herbaceous plant, with a perennial root, and an erect, round, channeled stem, from two to four feet high, furnished with opposite pinnate leaves, and terminating in flowering branches. The leaves of the stem are attached by short, broad sheaths; the radical leaves are larger and stand on long footstalks. In the former the leaflets are lanceolate and partially dentate, in the latter elliptical and deeply serrate. The flowers are small, white or rose-coloured, agreeably odorous, and disposed in terminal corymbs, interspersed with pear-shaped pointed bractes. The number of stamens is three. The fruit is a capsule containing one oblong-ovate, compressed seed. The plant is a native of Europe, where it grows either in damp woods and meadows, or on dry elevated grounds. As found in these different situations, it presents characters so distinct as to have induced some botanists to make two varieties. Dufresne makes four, of which three prefer marshy situations. The variety which affects a dry soil (*sylvestris*, L. Ph.) is not more than two feet high, and is distinguished by its narrow leaves. It has been generally believed to be superior to the others in medicinal virtue; but, from experiments of A. Buchner, it appears that the dried roots of the variety which grows in low moist grounds are in no respect inferior, and that the general opinion to the contrary is a prejudice. (*Pharm. Cent. Blatt*, June, 1852, p. 429.)

The root, which is the officinal portion, is collected in spring before the stem begins to shoot, or in the autumn when the leaves decay. It should be dried quickly, and kept in a dry place. It consists of numerous long, slender, cylindrical fibres, issuing from a tuberculated head or rhizoma. As brought to this country, it frequently has portions of the stem attached. The English is superior to that from the continent of Europe. Valerian of good quality has been produced by the Shakers at Enfield, New Hampshire. It is produced also in northern Vermont and New York. From our own observation, we know that the plant grows luxuriantly under culture in this country. Mr. Thos. Doliber obtained from the American root 28·97 per cent. of alcoholic extract, and from the English 17·59 per cent. Mr. Doliber states that the American has almost entirely superseded the European in our market. (*Am. Journ. of Pharm.*, Jan 1867, p. 70.)

Properties. The colour of the root is externally yellowish or brown, internally white. The powder is yellowish-gray. The odour, which in the fresh root is slight, in the dried is strong and highly characteristic, and, though rather pleasant to many persons, is very disagreeable to others. Cats are said to be strongly attracted by it. The taste is at first sweetish, afterwards bitter and aromatic. Valerian yields its active properties to water and alcohol. Trommsdorff found it to consist of 1·2 parts of volatile oil; 12·5 of a peculiar extractive matter, soluble in water, insoluble in ether and alcohol, and precipitated by metallic solutions; 18·75 of gum; 6·25 of a soft odorous resin; and 63 of lignin. Runge found in it a peculiar fixed acid, which produced with bases white salts, becoming green on exposure to the air. (*Chem. Gaz.*, no. 170, p. 452.) Of these constituents the most important is the *volatile oil.* It is of a pale-greenish colour, of the sp. gr. 0·934, with the pungent odour of valerian, and an aromatic taste. It becomes yellow and viscid by exposure.

Trommsdorff ascertained the existence in the oil of a peculiar volatile acid, upon which the name of *valerianic acid* or *valeric acid* has been conferred. This, when separated from the oil, is a colourless liquid, of an oleaginous consistence, having an odour analogous to that of valerian, and a very strong, sour, disagreeable taste. It is soluble in thirty parts of water, and in all proportions in ether and alcohol. It combines with salifiable bases, forming soluble salts, which retain, in a diminished degree, the odour of the acid. (*Journ. de Pharm.*, xx. 316.) From the experiments of MM. Cozzi and Thirault, it would appear that this acid does not pre-exist in the root, but results from the oxidation of the volatile oil. (*Ibid.*, 3e sér., xii. 162.) Valerianic acid is obtained by distilling the impure oil from carbonate of magnesia, decomposing by sulphuric acid the valerianate of magnesia which remains, and again distilling. M. Rabourdin, of Orleans, believing that a large proportion of the valerianic acid remains fixed in the root by union with a base, and does not come over by distillation alone, procures it by adding sulphuric acid to the root with a sufficient quantity of water, distilling, separating the oil, saturating the liquor with carbonate of soda, evaporating, adding a slight excess of sulphuric acid, and again distilling. (*Ibid.*, vi. 310.) The following process by Messrs. T. and H. Smith, of Edinburgh, avoids the inconvenience of distilling so bulky a root as valerian, while it answers the same purpose as that of M. Rabourdin. Boil the root for three or four hours with rather more than its bulk of water, in which an ounce of carbonate of soda is dissolved for every pound of the root, replacing the water as it evaporates. Express strongly, and boil the residuum twice with the same quantity of water, expressing each time as before. Mix the liquids, add two fluidrachms of strong sulphuric acid for every pound of the root, and distil till three-fourths of the liquid have passed over. Neutralize this with carbonate of soda, concentrate the liquid, decompose the valerianate of soda contained in it by sulphuric acid, and separate the valerianic acid set free, either by a separatory, or by distillation. (*Am. Journ. of Pharm.*, xvii. 253.) M. Lefort obtains the acid by the rapid oxidation of the volatile oil. He distils 100 parts of the root with 500 of water, 10 of sulphuric acid, and 6 of bichromate of potassa.

In this way he has procured a larger proportion of acid than by any other process. (*Journ. de Pharm.*, 3e sér., x. 194.)

The roots of *Valeriana Phu* and *V. dioica* are said to be sometimes mingled with those of the officinal plant; but the adulteration is attended with no serious consequences; as, though much weaker than the genuine valerian, they possess similar properties. The same cannot be said of the roots of several of the *Ranunculaceæ*, which, according to Ebermayer, are sometimes fraudulently substituted in Germany. They may be readily detected by their want of the peculiar odour of the officinal root. According to M. O. Raveil, the valerian in the markets of Paris is largely adulterated with the roots of *scabious* (*Scabiosa succisa* and *S. arvensis*, Linn.). They are shorter than the genuine root, with larger radicles, less rough, little or not at all striated, very brittle, with a white amylaceous fracture. The roots are inodorous in themselves, but acquire smell from contact with the valerian. (*Journ. de Pharm.*, xxvi. 209.)

Medical Properties and Uses. Valerian is gently stimulant, with an especial direction to the nervous system, but without narcotic effects. In large doses it produces a sense of heaviness and dull pain in the head, with various other effects indicating nervous disturbance. The oil, largely taken, is said by M. Barailer, from his own observation, to produce dulness of intellect, drowsiness ending in deep sleep, reduced frequency of pulse, and increased flow of urine. (See *Am. Journ. of Pharm*, May, 1861, p. 239.) It is useful in cases of irregular nervous action, when not connected with inflammation, or an excited condition of the system. Among the complaints in which it has been particularly recommended are hysteria, hypochondriasis, epilepsy, hemicrania, and low forms of fever attended with restlessness, morbid vigilance, or other nervous disorder. It has also been used in intermittents, combined with Peruvian bark. Mr. N. J. Butler, of Dublin, has found very great advantage in acute rheumatism from baths of valerian, made in the proportion of a pound of the root to 20 gallons of water, the temperature of the bath being 98°. Its power, in the opinion of Mr. Butler, is wonderful in cutting short the most violent attacks of acute rheumatic arthritis. (*Bost. Med. and Surg. Journ.*, Sept. 10, 1868, p. 95.) It may be given in powder or infusion. In the latter form, it is said by Professor Joerg, of Leipsic, who has experimented with it, to be less apt to irritate the alimentary canal than when administered in substance. The dose of the powder is from thirty to ninety grains, repeated three or four times a day. The tincture also is officinal. As the virtues of valerian reside chiefly in the volatile oil, the medicine should not be given in decoction or extract. The distilled water is used on the continent of Europe; and the volatile oil is occasionally substituted with advantage for the root. The dose of the oil is four or five drops. Valerianic acid also has been used internally; and a process is given in the U. S. Pharmacopœia for its preparation. (See *Acidum Valerianicum.*) Landerer says that, in his experience, the acid prepared from the root is preferable therapeutically to the artificial acid.

Vanilla.

The prepared, unripe capsules of Vanilla aromatica. *U. S.*

Vanilla. *Sex. Syst.* Gynandria Monandria.— *Nat. Ord.* Orchidaceæ.

Gen. Ch. Sepals spreading or erect, distinct. *Petals* of a similar form and texture. *Labellum* connate with the columna, crested, membranous, convolute, undivided. *Anther* terminal, opercular; pollen granular. *Fruit* a fleshy *pod;* seeds round, destitute of loose tunic. *Lindley.*

Vanilla aromatica. Schwartz, *Flor. Ind. Occid.*—*Epidendrum Vanilla.* Linn. This is a climbing plant, characterized, as a species, by its ovate, oblong,

nerved leaves, its wavy sepals, its acute lip, and very long cylindrical capsules. The stem is almost cylindrical, has about the thickness of the little finger, is greenish and fleshy, and is furnished with occasional nodes, each of which has a thick opposite leaf, of about eight inches by three. Its roots penetrate the bark of the tree to which it is attached, from which they obtain nourishment for the plant. After a certain height the stem branches, and forms a spreading top, which, in due season, is covered with large flowers, greenish externally and white within. The fruit is a slender pod, seven or eight inches long, filled with an oily mass containing numerous small, black, shining seeds. The plant is a native of the West Indies, Mexico, and South America; and is said to be cultivated in the Isles of France and Bourbon. Doubts, however, exist whether the best commercial vanilla is derived from this species, and some ascribe it to *Vanilla planifolia.* (*Journ. de Pharm.*, xvi. 274.) It is probable that different varieties of the vanilla of commerce are obtained from different species, of which several, besides the two mentioned, have been described as yielding an aromatic fruit, as *V. Guyanensis*, *V. palmarum*, and *V. pompona.* In Mexico the plant flourishes on the eastern coast, in the States of Vera Cruz and Oaxaca. It begins to bear fruit in three years, and continues to bear thirty or forty years. Though most of the vanilla of commerce is derived from plants growing wild in the forests, yet much is the product of a species of cultivation, which is very simple. All that is necessary is to cut a slip of the stem from the lower part, and plant it near the trunk of a tree, attaching it by cords. The plant immediately takes root in the bark of the tree, and sends out air roots, which, reaching the ground, fix themselves in the soil. The fruit is ready for collection about the end of March, and the harvest continues three months. (Müller, *Am. Journ. of Pharm.*, Jan 1866, p. 38; from *Vierteljahresschrift für Pharm.*)

The pods are collected before they are quite ripe, dried in the shade, covered with a coating of fixed oil, and then tied in bundles, which are surrounded with sheet lead, or enclosed in small metallic boxes, and sent into the market. Several varieties of vanilla exist in commerce. The most valuable, called *ley* by the Spaniards, consists of cylindrical, somewhat flattened pods, six or eight inches long, three or four lines thick, nearly straight, narrowing towards the extremities, bent at the base, shining and dark-brown externally, wrinkled longitudinally, soft and flexible, and containing within their tough shell a soft black pulp, in which numerous minute, black, glossy seeds are embedded. It has a peculiar, strong, agreeable odour, and a warm, aromatic, sweetish taste. The interior pulpy portion is most aromatic. Another variety, called *simarona* by the Spaniards, is smaller, of a lighter colour, and less aromatic. A third variety is the *pompona* of the Spaniards. In this, the pods are from five to seven inches long, from six to nine lines broad, almost always open, brown, soft, viscid, and of a strong odour, but less pleasant than that of the *ley*, to which it is considered inferior. According to Bucholz, vanilla does not yield volatile oil when distilled with water; and the aroma appears to depend on chemical changes which take place during and after the curing of the fruit.

Many years since, vanilla was analyzed by Bucholz and Vogel, the former of whom found in it a disagreeably smelling fixed oil, a soft resin smelling feebly of vanilla when heated, a bitterish extractive resembling tannin, sugar, starch, and benzoic acid. But the characteristic odorous principle was not isolated. This object was accomplished by M. Gobley, who, by exhausting vanilla with alcohol of 85°, evaporating the resulting tincture to an extract, softening this with water, and agitating in a flask with ether so long as it gave colour to that fluid, then evaporating the ethereal liquid and treating the residue with boiling water, obtained, on the evaporation of the water, a crop of crystals having the odour of vanilla. Purified by treatment with animal charcoal, and recrystallization, the new principle appeared in the form of colourless, long, four-sided needles, terminated by two faces. It has a strong odour of vanilla, with a hot, biting taste. The crystals are hard, and crack under the teeth

They melt at 195° F., and sublime, at 302° F., in minute needle-shaped crystals, of a shining whiteness. For this substance M. Gobley proposes the name of *vanillin.* It is of difficult solubility in cold water, but is largely dissolved by boiling water, which deposits it on cooling. It is very soluble in alcohol, ether, and the fixed and volatile oils. Diluted acids dissolve it without change. Concentrated sulphuric acid dissolves it, but renders it yellow. Solution of potassa also dissolves it, and yields it unaltered on the addition of an acid. It does not decompose alkaline carbonates, and is probably, therefore, not an acid. Its composition is represented by the formula $C_{20}H_8O_4$. It is analogous to the coumarin of the Tonka bean, but is not identical with it. When the vanilla pods are enclosed in cases, it often happens that they are covered with a white frost-like efflorescence of minute crystals. These were considered by Bucholz and Vogel as benzoic acid. M. Gobley believes that they are vanillin, the vapours of which, given out by the fruit, condense like frost on its surface. (*Am. Journ. of Pharm.*, March, 1859, p. 130; from *Journ. de Pharm.*, Janv. 1859.) Mr. Stokeby has subsequently confirmed the statement of M. Gobley as to the nature of the frost-like efflorescence on the surface of the bean; but, believing that he has found it to have feeble acid properties, he proposes to call it *vanillic acid.* The formula of Mr. Stokeby differs greatly from that of Gobley, being $C_{34}H_{22}O_{20}$. According to Stokeby, vanillin dissolves in its weight of alcohol and boiling ether, one part dissolves in 11 parts of boiling water, and in 198 parts at 59° F. The sesquichloride of iron gives to all its solutions a fine, deep violet colour. It passes with water in distillation. If vanilla finely divided be distilled with water, a turbid liquid passes, which becomes clear by agitation with ether; and the ether on evaporation yields crystals of vanillin. Mr. Stokeby found in vanilla resin, wax, a fixed oil, a brown resinous matter, tannic acid changing the salts of iron to green, gum, sugar, phosphates, and sulphates; and muriatic acid separated from it oxalic acid, and potassa humic acid. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 76, A.D. 1866.)

Medical Properties and Uses. Vanilla has the properties of the aromatics generally, but is probably more diffusibly stimulant, with some influence on the nervous system. It is employed more as a perfume, and to flavour chocolate, ice-cream, &c. than as a medicine. It has, however, been recommended as a remedy in hysteria and low fevers, in the form of an infusion made in the proportion of about half an ounce to a pint of boiling water, and given in table spoonful doses. A fluid extract would be a convenient form for exhibition.*

VERATRUM. *Sex. Syst.* Polygamia Monœcia. — *Nat. Ord.* Melanthaceæ.

* *Fluid Extract of Vanilla.* This is prepared by Prof. Procter in the following manner. An ounce of vanilla, cut transversely into short pieces, is beaten with two ounces of sugar and a little alcohol into a pulp, and then submitted to percolation, first with four fluidounces of deodorized alcohol, and afterwards with diluted alcohol, until twelve fluidounces of tincture are obtained. Two ounces of sugar are added to the tincture, which is then evaporated with a gentle heat to six fluidounces. Lastly, ten ounces of sugar are added, and sufficient water to make the whole measure a pint. (*Am. Journ. of Pharm.*, xxvi. 300.) This fluid extract may be given in the dose of one or two fluidrachms. It is a very convenient form for the use of vanilla as a flavouring substance.

A Syrup of Vanilla may be prepared by mixing two fluidounces of this fluid extract with two pints of simple syrup. If a perfectly transparent syrup is wanted, rub two ounces of the fluid extract with two drachms of carbonate of magnesia, and half a pint of water gradually added; filter the mixture; then add another half pint of water, and two and a half pounds of sugar; dissolve the sugar with the aid of heat; and, lastly, strain the syrup. The syrup is fitted rather for giving flavour to mixtures, either medicinal or dietetic, than for remedial effect.

Gen. Ch. HERMAPHRODITE. *Calyx* none. *Corolla* six-petaled. *Stamens* six. *Pistils* three. *Capsules* three, many-seeded. MALE. *Calyx* none. *Corolla* six-petaled. *Stamens* six. *Pistils* a rudiment. *Willd.*

Botanists who reject the class *Polygamia* of Linnæus, place this genus in the class and order *Hexandria Trigynia*, with the following character. "Polygamous. *Corolla* six-parted, spreading, segments sessile without glands. *Stamens* inserted upon the receptacle. *Capsules* three, united, many-seeded." *Nuttall.*

Veratrum album. Willd. *Sp. Plant.* iv. 895; Woodv. *Med. Bot.* p. 754, t. 257. This is an herbaceous plant, with a perennial, fleshy, fusiform root or rhizoma, yellowish-white externally, pale yellowish-gray within, and beset with long cylindrical fibres of a grayish colour, which constitute the true root. The stem is three or four feet high, thick, round, erect, and furnished with alternate leaves, which are oval, acute, entire, plaited longitudinally, about ten inches long by five in breadth, of a yellowish-green colour, and embrace the stem at their base. The flowers are greenish, and arranged in a terminal panicle.

White hellebore is a native of the mountainous regions of continental Europe, and abounds in the Alps and Pyrenees. All parts of the plant are said to be acrid and poisonous; but the root (rhizoma) only is officinal. This is brought from Germany in the dried state, in pieces from one to three inches long by an inch or less in mean diameter, cylindrical or in the shape of a truncated cone, internally whitish, externally blackish, wrinkled, and rough with the remains of the fibres which have been cut off near their origin. Sometimes the fibres continue attached to the root. They are numerous, yellowish, and of the size of a crow's quill. White hellebore deteriorates by keeping.

Properties. The fresh root has a disagreeable odour, which is lost by drying. The taste is at first sweetish, and afterwards bitterish, acrid, burning, and durable. The powdered root is grayish. Analyzed by Pelletier and Caventou, white hellebore was found to contain an oily matter consisting of olein, stearin, and a volatile acid; *supergallate of veratria;* a yellow colouring matter; starch, gum, and lignin; silica, and various salts of lime and potassa. The medicinal properties of the root reside in the veratria, which was first discovered in the seeds of *Veratrum Sabadilla*, and probably exists in other plants belonging to the same family. (See *Veratria* in *Part* II.) Simon believed that he had found two new vegetable alkalies in white hellebore, one of which was named *barytina*, from being precipitated, like baryta, from its solution in acetic or phosphoric acid by sulphuric acid or the sulphates; the other *jervina*, from the Spanish name for a poison obtained from the root of white hellebore. (*Pharm. Cent. Blatt*, 1837, p. 191.)

Medical Properties and Uses. White hellebore is a violent emetic and cathartic, capable of producing dangerous and fatal effects if incautiously administered. Even in small doses it has occasioned severe vomiting, hypercatharsis with bloody stools, and alarming general prostration. Like many other acrid substances, it appears, in small doses, to be a general stimulant to the secretions. Applied externally upon a portion of the surface denuded of the cuticle, as upon ulcers, for example, it gives rise to griping pain in the bowels, and sometimes violent purging. When snuffed up the nostrils, it occasions great irritation with violent sneezing, and its use in this way is not free from danger. It was employed by the ancients in dropsy, mania, epilepsy, leprosy, elephantiasis, and other obstinate disorders, not without occasional advantage; but the severity of its action has led to its general abandonment. It is sometimes used as an errhine, diluted with some mild powder, in cases of gutta serena and lethargic affections; and the decoction, and an ointment prepared by mixing the pulverized root with lard, have been found beneficial as external applications in the itch, and other cutaneous eruptions. From the resemblance of its operation to that of the *eau médicinale d'Husson*, so celebrated for the cure of gout, it was at one time, though erroneously, conjectured to be the chief constituent of that remedy. A mixture of the wine of white hellebore and the wine of opium, in the proportion of three parts of the former to one of the latter, was introduced into use by Mr. Moore, of London, as a substitute for the *eau médicinale.*

In whatever way white hellebore is used, it requires cautious management. It has been given in doses varying from one grain to a scruple. Not more than two grains should be administered at first. When employed as an errhine, it should be mixed with five or six parts of pulverized liquorice root, or other inactive powder. Ten or twelve grains of the mixture may be snuffed up the nostrils at one time. W.

VERATRUM VIRIDE. *U. S.*

American Hellebore.

The rhizoma of Veratrum viride. *U. S.*

Off. Syn. VERATRI VIRIDIS RADIX. *Green Hellebore Root.* The dried rhizome of Veratrum viride. Collected in autumn in the United States and Canada. *Br.*

VERATRUM. See VERATRUM ALBUM.

Veratrum viride. Willd. *Sp. Plant.* iv. 896; Bigelow, *Am. Med. Bot.* ii. 121. The American hellebore, known also by the names of *Indian poke, poke root,* and *swamp hellebore,* has a perennial, thick, fleshy root or rhizoma, the upper portion of which is tunicated, the lower solid, and beset with numerous whitish fibres or radicles. The stem is annual, round, striated, pubescent, and solid, from three to six feet in height, furnished with bright-green leaves, and terminating in a panicle of greenish-yellow flowers. The leaves gradually decrease in size as they ascend. The lower are from six inches to a foot long, oval, acuminate, plaited, nerved, and pubescent; and embrace the stem at their base, thus affording it a sheath for a considerable portion of its length. Those on the upper part of the stem, at the origin of the flowering branches, are oblong-lanceolate. The panicle consists of numerous flowers, distributed in racemes with downy peduncles Each flower is accompanied with a downy, pointed bracte, much longer than its pedicel. There is no calyx, and the corolla is divided into six oval acute segments, thickened on the inside at their base, with the three alternate segments longer than the others. The six stamens have recurved filaments, and roundish two-lobed anthers. The germs are three, with recurved styles as long as the stamens. Some of the flowers have only the rudiments of pistils. Those on the upper end of the branchlets are barren, those on the lower portion fruitful. The fruit consists of three cohering capsules, separating at top, opening on the inner side, and containing flat imbricated seeds.

This indigenous species of Veratrum is found from Canada to the Carolinas, inhabiting swamps, wet meadows, and the banks of mountain streamlets. Early in the spring, before the stem rises, it bears a slight resemblance to the *Symplocarpus fœtidus,* with which it is very frequently associated; but the latter sends forth no stem. From May to July is the season for flowering. The root should be collected in autumn, and should not be kept longer than one year, as it deteriorates by time.

Properties. As found in the shops, it is usually in small pieces or fragments; but sometimes it comes whole or merely sliced, so that its characteristic form may be observed. In this condition it is seen to consist of a rhizoma an inch or two in length by somewhat less than an inch in thickness where broadest, tapering to a very obtuse or truncated extremity, compact but light, of a dark-brown colour externally, and either closely invested with numerous yellowish rootlets often several inches long, or exhibiting marks on the surface whence they have been removed. When sliced, the cut surface is of a dingy-white colour. The rootlets are about as thick as a large knitting-needle, or somewhat thicker, obviously much shrunk in drying, and marked by numerous close-set indentations, which give them a characteristic appearance. Not unfrequently portions of the dried stem or leafstalks remain attached to the rhizoma, which should always be rejected, as they have been ascertained by Prof. Procter to be inert. (*Am. Journ. of Pharm.*, March, 1864, p. 99.) The root has a bitter, acrid taste, leaving a permanent impression in the mouth and fauces In sensible properties it bears a close resemblance to white hellebore; and has been shown by

the experiments of Mr. J. G. Richardson, of Philadelphia, to contain veratria, or at least an alkaloid closely analogous to it. (*Am. Journ. of Pharm.*, xxix. 204.) Mr. J. C. Scattergood, by adding water to a saturated tincture of the root, and afterwards evaporating the alcohol, obtained a resinous precipitate, while from the residuary liquid he succeeded in separating an alkaloid supposed to be veratria. By experimenting separately with the alkaloid and the resin thus procured, Dr. S. R. Percy, of New York, obtained effects to a certain extent similar, and such as characterize the operation of the root, with this remarkable difference, however, that while both substances produced vomiting and prostration, the resin had a much more powerful influence in reducing the frequency of the pulse. Thus while, in one dog, under the action of the veratria, the pulse was reduced from 148 to 112; in another, under that of the resin, with no greater effect in other respects, it fell from 144 to 40; and this result was so constant that it could not be ascribed to accident. A very important inference is that there is a principle in the American hellebore distinct from veratria, upon which its remarkable powers over the circulation mainly depend. There can be little doubt that the so-called resin will be found to be a complex body, possibly containing a distinct alkaloid. (*Ibid.*, Jan 1863, p. 74.)

To bring down the history of the alkaloid matter of veratrum viride to the present date (Feb. 1869), it is necessary to refer to the recent investigations of Mr. Charles Bullock, the results of which, thus far obtained, appear to be that there are two alkaloids in veratrum viride, neither of which is identical with veratria, that one of these alkaloids is soluble, the other insoluble in ether, and that the resin, supposed to possess the sedative property of the drug, owes this property to the presence of the alkaloid insoluble in ether, for which it has an extraordinary affinity, but, entirely deprived of which, it has no effect on the pulse.*

* The two alkaloids were obtained by Mr. Bullock in the following manner. From a concentrated tincture, acidulated with acetic acid, the resin was thrown down by the addition of water, and was collected on a filter. The liquid was concentrated, and, after filtration to separate the remaining resin, a little alcohol was added, to prevent the precipitation of colouring matter, and carbonate of soda sufficient to induce decided alkaline reaction. On the latter addition, the solution became dark and opaque; a further addition of the carbonate increased the precipitation; and now the solution assumed a clear wine-red colour. The precipitate was washed, dried, dissolved in alcohol, and treated with purified animal charcoal. The alcoholic solution was evaporated; the residue was dried and treated at a moderate heat, with water acidulated with sulphuric acid: on cooling, colouring matter was deposited, which was separated by filtration; and the solution was now precipitated with carbonate of soda. The precipitate, having been washed on a filter till the water passed colourless, was again dissolved in water acidulated with sulphuric acid, and digested with animal charcoal. The solution was again precipitated with carbonate of soda; and the precipitate, being washed to separate alkaline carbonates, and dried at a moderate heat, was reduced to powder, and agitated with successive portions of ether free from alcohol, which dissolved out the alkaloid, and left it on evaporation as a light-yellow residue, which was detached from the glass capsule in scales resembling tannin. The parts undissolved by ether contained a considerable proportion of the alkaloid insoluble in ether, which was extracted by alcohol, and obtained separate by evaporation. As both the ethereal and the alcoholic products were somewhat coloured, they were severally dissolved in acidulated water, and precipitated by very dilute ammonia, a little alcohol being added to the solution to retain the colouring matter. The two alkaloids were thus obtained colourless; the one soluble in ether being when dried in a soft pulverulent condition; the one insoluble, hard and of a semi-resinous form adhering to the filter. As the discoverers of these alkaloids have modestly avoided assigning them names, and yet these are essential in description, in order to avoid inconvenient circumlocution; we provisionally suggest the title of *veratroidia* for the one soluble in ether, expressive of its close analogy with veratria, and *viridia* for the one insoluble in ether, as representing more closely than the other the peculiar sedative influence of the root. Viridia exists largely in the resinous precipitate thrown down from a concentrated tincture of the root, and is held by the resin with great tenacity. To separate the alkaloid, Mr. Bullock, after exhausting the resin with ether, redissolved it in alcohol, and again precipitated by pouring it into acidulated water; and this operation was repeated several times. At length the resin was dried, powdered, and washed on a filter with acidulated water, until the water was no longer disturbed by neutralization with an alkaline carbonate. On a careful examination of the resin now left, it was found to be free from the alkaloid, and

Medical Properties and Uses. American hellebore has been thought to resemble its European congener in its effects upon the system, though asserted by Dr. Osgood to be wholly destitute of cathartic properties.* In addition to its emetic action, which is often violent and long continued, it is said to increase most of the secretions, and, when freely taken, to exercise a powerful influence over the nervous system, indicated by faintness, somnolency, vertigo, headache, dimness of vision, and dilated pupils. According to Dr. Osgood, it reduces the frequency and force of the pulse, sometimes, when taken in full doses, as low as thirty-five strokes in the minute. It may be safely substituted for the European root in most cases in which the latter is employed, and is highly recommended as a substitute for colchicum by Dr. Tully, of New Haven. Gouty, rheumatic, and neuralgic affections are those to which it appeared best adapted. For an account of its medical properties and applications, the reader is referred to a paper by Dr. Charles Osgood, of Providence, in the *American Journal of the Medical Sciences* (xvi. 296). It may be used in substance, tincture, or extract. Dr. Osgood states the dose in which it will generally prove emetic at

taken internally in doses of one-third of a grain every half hour, until two grains had been taken altogether, produced no effect on the force or frequency of the pulse, and no other inconvenience than certain dyspeptic sensations. To procure the alkaloid it only remained to neutralize the acidulated solution with carbonate of soda.

Properties of the alkaloids. Neither of them exhibited any evidence of crystallization. In alcoholic solution they restored reddened litmus paper to its normal colour. They were slightly bitter, and dissolved freely in dilute sulphuric, nitric, muriatic, and acetic acids Both were soluble in alcohol, amylic alcohol, and chloroform; but neither of them in benzole. Both were precipitated from their solutions in acidulated water by alkalies and their carbonates, and were not redissolved by an excess of the precipitant. Both gave a precipitate with perchloride of gold, and copious white precipitates with iodohydrargyrate of potassium. Their reactions, moreover, with the concentrated mineral acids were nearly the same; their solutions in concentrated sulphuric acid being first reddish-yellow, then ochry-red, and finally brown; in nitric acid, colourless or with a slight evanescent rose hue; and in muriatic acid, if in the cold faintly yellow, deepened by boiling, and after 24 hours a turbid green.

Veratroidia. Solubility in ether is its chief recognized characteristic. It is fusible between 270° and 275° F., in this respect differing from veratria, the melting point of which, according to Soubeiran, is 239° F. It differs also in not producing intense redness by contact with concentrated sulphuric acid, and does not answer to Trapp's test of veratria; that is, dissolving in cold muriatic acid without change of colour; but when boiled assuming a red colour, which finally becomes intense, resembling that of a solution of permanganate of potassa. In its effects on the system it is said closely to resemble veratria, acting like that also as a violent irritant to the nostrils; and it is highly probable that most of the irritant effects of veratrum viride on the stomach are ascribable to the veratroidia.

Viridia. This is prominently characterized by its insolubility in ether. It has a considerably higher melting point than veratroidia, requiring from 335° to 340° F. for fusion. Viridia slightly irritates the nostrils, though much less than the other alkaloid; but its effect in reducing the pulse is much greater. Mr. Bullock states, as the result of several trials with persons in health, that one-fortieth of a grain of the alkaloid, dissolved in alcohol, given every 15 minutes till one-eighth of a grain had been administered, caused in half an hour after the last dose, in every case, a reduction of the pulse of from 8 to 12 beats in the minute. No nausea or other effect was experienced, except an impression on the throat resembling that of pyrethrum; nor was any benumbing effect noticed. From the peculiar physiological action of viridia, it is highly desirable that it should be therapeutically investigated; as it may be a valuable substitute for veratrum viride, possessing all its sedative powers, without the irritant properties that sometimes interfere with the beneficial influence of that medicine.

Now that the existence of two distinct alkaloid principles in veratrum viride is determined, it is much to be desired that their chemical, physiological, toxicological, and therapeutical properties should be systematically and fully investigated. (Wm. Bullock, *Am. Journ. of Pharm.*, Sept. 1865, p. 321; and March, 1866, p. 97; also *Proceedings of the Am. Pharm. Association*, 1867.)—*Note to the thirteenth edition.*

* The most striking difference between this and V. album appears, from the experiments of Dr. Oulmont, of Germany, on the lower animals, to be the extraordinarily irritant effect on the alimentary canal of the V. album, not only causing vomiting and purging, but positive inflammation capable of causing death; while the V. viride, though causing nausea, vomiting, and diarrhœa, and even fatal prostration, gives rise to not the least trace of gastro-intestinal inflammation. (*Neues Repertorium*, xvii. 177, A. D. 1868.)

from four to six grains of the powder, one or two fluidrachms of a tincture made of six ounces of the fresh root and a pint of alcohol, and one or two grains of an extract made by inspissating the juice of the root. The medicine, however, should, in most cases, be given in doses insufficient to vomit.

After the publication of Dr. Osgood's paper, little attention was paid to the subject until a few years since, when various communications appeared in our Southern medical journals, tending to prove that American hellebore is applicable to the treatment of numerous febrile and inflammatory affections, in which an indication is offered for reducing the frequency of the pulse. The credit of calling public attention to it is due more especially to Dr. W. C. Norwood, of Cokesbury, South Carolina, who employed it with great success in pulmonary inflammation, typhoid fever, &c., and believed that it afforded the means of reducing the frequency of the pulse at will. He used a saturated tincture, made by macerating eight ounces of the dried root in sixteen ounces of alcohol for at least two weeks. Of this he gave to an adult man eight drops, and repeated the dose every three hours, increasing by one drop at each dose, until the pulse was reduced, or nausea and vomiting were occasioned, when it was to be diminished one-half, and continued so long as might be necessary to prevent a return of the symptoms. (*Charleston Med. Journ. and Rev.*, vii. 768.) From numerous communications subsequently made to the journals, there can be no doubt of the great efficiency of this remedy in reducing the circulation; and many practitioners speak with great confidence of its usefulness in pneumonia, diseases of the heart with excessive action, inflammatory rheumatism, and other inflammatory and febrile diseases with a greatly excited circulation. The author has used it with decided effect in reducing the frequency of the pulse in cardiac affections, and without materially deranging the stomach. It is said to have cured habitual constipation, given in the dose of three drops of the tincture five times a day. Recovery took place in two weeks. (*Med. Record.*, Sept. 15, 1868, p. 320.) Some have found the original commencing dose of Dr. Norwood too large, and he himself has considerably reduced it; but from three to six drops of the saturated tincture, repeated every three hours, and gradually increased, if necessary, until its effects are experienced, may be given with safety. From its powerful emetic properties, and the prostration resulting from excessive doses, it should always be used with great caution, and its effects carefully observed.* Its nauseating and depressing effects are best counteracted by opiates and alcoholic stimulants. A tincture and fluid extract have been introduced into the U. S. Pharmacopœia. (See these preparations in *Part* II.)

Cases of extreme prostration have occurred from abnormally large doses of American hellebore, and sometimes even from moderate doses in instances of extreme constitutional susceptibility; yet no case of death from it in an adult has come to our notice. That it is capable, however, of producing fatal effects is evident from experiments on the lower animals, and from the case of a child of 18 months, under the care of Dr. J. C. Harris, of West Cambridge, Mass., to which about 35 drops of the tincture were given by mistake, with the effect of inducing nausea but not effectual vomiting, great prostration in which the pulse was reduced to 40, loss of consciousness, and ultimately death. (*Am. Journ. of Pharm.*, Sept. 1865, p. 374.)

Vin rouge, *Fr.;* Rother Wein, *Germ.;* Vino vermiglio, *Ital.;* Vino tinto, *Span.*

Wine is the fermented juice of the grape, the fruit of Vitis vinifera of botanists. (See *Uva Passa.*) The juice of sweet grapes consists of a considerable quantity of grape sugar, a peculiar matter of the nature of ferment or yeast, and a small portion of extractive, tannic acid, bitartrate of potassa, tartrate of lime, common salt, and sulphate of potassa; the whole dissolved or suspended in a large quantity of water. Sour grapes contain, in addition, a peculiar acid isomeric with the tartaric, called *paratartaric acid.* (See *page* 70.) Grape juice, therefore, embraces all the ingredients essential to the production of the vinous fermentation, and requires only the influence of the atmosphere and a proper temperature to convert it into wine. (See *page* 77.)

Preparation. When the grapes are ripe, they are gathered, and trodden in wooden vessels with perforated bottoms, through which the juice, called the *must*, runs into a vat placed beneath * The temperature of the air being about 60°, the fermentation gradually takes place in the must, and becomes fully established after a longer or shorter period. In the mean time, the must becomes sensibly warmer, and emits a large quantity of carbonic acid, which causes the more solid parts to be thrown to the surface in a mass of froth, having a hemispherical shape, called the *head.* The liquor from being sweet becomes vinous, and assumes a deep-red colour if the product of red grapes. After a while the fermentation slackens, when it becomes necessary to accelerate it by thoroughly mixing the contents of the vat. When the liquor has acquired a strong vinous taste, and become perfectly clear, the wine is considered formed, and is racked off into casks. But even at this stage of the process, the fermentation continues for several months longer. During the whole of this period, a frothy matter is formed, which for the first few days collects round the bung, but afterwards precipitates along with colouring matter and tartar, forming a deposit which constitutes the wine lees.†

Division and Nomenclature. Wines, according to their colour, are divided into the red and white; and, according to their taste and other qualities, are either spirituous, sweet, dry, light, sparkling, still, rough, or acidulous. *Red wines* are derived from the must of black grapes, fermented with their husks; *white*

* A new mode of extracting the grape juice has been devised by M. Richter, of Stuttgard. He puts the grapes in a drum, provided with a suitable strainer, and rotates this at the rate of 1000 or 1500 times in a minute; the centrifugal force being the expressing agency. The time by this method is greatly diminished, and the quantity of juice is increased 5 or 6 per cent. (*Am. Journ. of Pharm.*, Sept. 1865, p. 395.)—*Note to the thirteenth edition.*

† In certain parts of France, the wine-makers are in the habit, during the fermentation of the wines upon the marc, of adding plaster of Paris, under the impression that it improves the colour and ensures the stability of the wines. The process is called by the French *plâtrage.* The chemistry of the process has recently been investigated by M. Chancel, and MM. Bussy and Buignet, who coincide in the conclusion that, through the agency of the sulphate of lime, a portion of the bitartrate of potassa in the grape, which is but partially dissolved by the wine, in consequence of its limited solvent power, is introduced into the wine, increasing its acidity, and contributing to its stability. But these chemists differ as to the precise nature of the change. Thus, while M. Chancel thinks that the reaction between the sulphate of lime and bitartrate of potassa results in the production of free tartaric acid and sulphate of potassa which dissolve, and tartrate of lime which remains in the marc; MM. Bussy and Buignet, agreeing with the former that tartaric acid, sulphuric acid, and potassa are imparted to the wine, each in the proportion of a single equivalent, yet believe them to be so combined as to form bitartrate of potassa and bisulphate of potassa; the increased acidity being ascribable to the bisulphate; and, considering the peculiar affinities brought into play, this is undoubtedly, we think, the correct view. Whether the introduction of this new component into wines is beneficial or otherwise, they do not pretend to determine. (*Journ. de Pharm. et de Chim.*, 4e sér., i. pp. 347 and 351.)—*Note to the thirteenth edition.*

wines, from white grapes, or from the juice of black grapes, fermented apart from their husks.* The other qualities of wines, above enumerated, depend on the relative proportions of the constituents of the must, and on the mode in which the fermentation is conducted. The essential ingredients of the must as a fermentable liquid are water, sugar, and a ferment. If the juice be very saccharine, and contain sufficient ferment to sustain the fermentation, the conversion of the sugar into alcohol will proceed until checked by the production of a certain amount of the latter, and there will be formed a *spirituous* or *generous* wine. If, while the juice is highly saccharine, the ferment be deficient in quantity, the production of alcohol will be less, and the redundancy of sugar proportionably greater, and a *sweet wine* will be formed. When the sugar and ferment are in considerable amount, and in the proper relative proportions for mutual decomposition, the wine will be strong-bodied and sound, without marked sweetness or acidity, and of the kind called *dry*. A small proportion of sugar can give rise only to a small proportion of alcohol, and consequently the less saccharine grapes will generate a comparatively weak, or *light wine*, which will be sound and stable in its constitution, in case the ferment is not in excess, but otherwise liable to pass into the acetous fermentation and become acescent. In case the wine is bottled before the fermentation is fully completed, the process will go on slowly in the bottles, and the carbonic acid generated, not having vent, will impregnate the wine, and render it effervescing and *sparkling*. The *rough* or *astringent* wines owe their flavour to a portion of tannic acid derived from the husks of the grape; and the *acidulous* wines to the presence of carbonic acid, or of an unusual proportion of tartar. Several of the above qualities often coexist. Thus a wine may be spirituous and sweet, spirituous and rough, sweet and rough, light and sparkling, &c. Wines are made in many countries, and are known in commerce by various names, according to their source. Thus, *Portugal* produces port and lisbon; *Spain*, sherry, saint lucar, malaga, and tent; *France*, champagne, burgundy, hermitage, vin de grave, sauterne, and claret; *Germany*, hock and moselle; *Hungary*, tokay; *Sicily*, marsala or Sicily madeira, and lisa; the *Cape of Good Hope*, constantia; *Madeira* and *the Canaries*, madeira and teneriffe.

In the United States the first attempt to manufacture wine, on an extended scale, was made towards the close of the last century, at Spring Mill, near Philadelphia, by Peter Legaux, agent of the Pennsylvania Vine Company, and proved unsuccessful. The native grape found most suitable by the Company, after the foreign had failed on account of the climate, was the *Schuylkill muscadel grape*. The next attempt was made by the Swiss at Vevay, Indiana, with the Schuylkill grape, and was partially successful; a rough red wine being manufactured which met with a ready sale in the neighbouring States. In a few years the manufacture of this wine languished; foreign wines superseding it. The foreign grape, after numerous trials, not succeeding as a wine grape, investigations were undertaken to determine the adaptation of our various native grapes for making wine. Among these the *Catawba grape*, a native of North Carolina, introduced to public notice by Major Adlum, of Washington City, about the year 1825, is the most esteemed; being largely cultivated in southern Ohio as a wine grape. The chief objection to it is its liability to the rot. The Isabella grape is also cultivated, but more for the table than for wine. It is claimed by some to be a native; but the evidence preponderates in favour of its foreign origin. The wine produced by the Catawba grape, called *catawba wine*, is of three kinds; the still, the sparkling, and the sweet. *Still catawba*, the result of a completed fermentation, is a light, dry, acidulous wine, in these particulars

* The colouring matter of the grape is almost insoluble in water, and hence the juice of the red grape is nearly colourless, and will produce a white wine if fermented alone; but when fermented with the presence of the grape, the alcohol generated dissolves the colouring matter, which is soluble in that liquid; and thus the wine becomes red. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 340, A. D. 1866.)—*Note to the thirteenth edition.*

like hock, but entirely different in flavour. It has a pinkish or straw colour. *Sparkling catawba* is made by letting the wine undergo the secondary fermentation in the bottle. It looks like champagne, but has a different and peculiar taste. *Sweet catawba* resembles the lighter sweet wines of Europe, and is prepared by adding sugar to the grape juice before fermentation. These native wines are gradually coming into use, and constantly improving in quality. They are largely manufactured by Mr. N. Longworth, of Cincinnati. The average product of catawba wine is 400 gallons to the acre, and the amount produced in Ohio in 1855 was estimated at 400,000 gallons. (See the remarks of E. S. Wayne, of Cincinnati, in the *Am. Journ. of Pharm.*, Nov. 1855, p. 494.) The *Herbemont* and *Missouri* grapes are also used for making wine; the latter producing a wine said to resemble madeira. The *Scuppernong grape*, indigenous to North Carolina, yields a hard dry wine; and the vine is said to be a very abundant bearer. According to Mr. R. Buchanan, this grape produces from two to three thousand gallons of wine per acre. (*Treatise on the Cultivation of the Grape.* Cincinnati, 1850.) The climate of Texas is peculiarly favourable to the growth of the grape vine. The *El Paso grape* is found in the vicinity of the falls of the Rio Grande; and the *great mustang* grows luxuriantly in every part of the State, and yields a superior red wine. California is rich in native grapes, and produces a considerable quantity of wine, which is now coming into general use. Considering its advantages of soil and climate, there is good reason to believe that it may, at no very distant time, rank among the most productive wine-regions of the globe. At present the grape, for wine-making, is successfully cultivated in eighteen States of the Union. The wine crop of the whole United States for the year 1857 was estimated at three millions of gallons. (Stearns, *Penins. Journ.*, July, 1858, p. 203.) A misfortune in reference to our domestic wines is that, to supply the demand, they are too often sold soon after being made, so that they have not had the opportunity of ripening with age. (*Ibid.*)

Properties. Wine, considered as the name of a class, may be characterized as a spirituous liquid, resulting from the fermentation of grape juice, and containing colouring matter, and other substances, either combined or intimately blended with the spirit. It always contains a small proportion of aldehyd. (*Magnes Lahens.*) All its other qualities vary with the nature of each particular wine. The principal wines used for medicinal purposes are the officinal wines, sherry and port, together with madeira, teneriffe, claret, and champagne.

Sherry (Vinum Xericum) is of a deep-amber colour, and when good possesses a dry aromatic flavour and fragrancy, with very little acidity. It ranks among the stronger white wines, and contains, on an average, 19 per cent. by measure of alcohol. The U. S. and British Pharmacopœias agree in indicating it as the officinal white wine. It is prepared in the vicinity of Xeres, in Spain, and hence its English name *sherry*. This wine is supposed to have been the *sack* of Shakspeare, so called from the word *sec* (dry). Mr. Henry Long has found about a grain of sulphuric acid in an ounce and a half of sherry wine, and supposes it to be free; but in the light of the experiments of MM. Bussy and Buignet (see note, *page* 890), it is, we think, more likely to be in the state of bisulphate of potassa, resulting from the reaction between bitartrate of potassa, and sulphate of lime used in preparing the wine. (*Pharm. Journ.*, June, 1867, p. 732.)

Port (Vinum Portense) is of a deep-purple colour, and, in its new state, is a rough, strong, and moderately sweet wine. When kept a certain time in bottles, it deposits a considerable portion of its astringent matter, loses the greater part of its sweetness, acquires more flavour, and retains its strength. If too long kept, it deposits the whole of its astringent and colouring matter, and becomes deteriorated. Considerable quantities of brandy are usually added to it, which causes its heating quality on the palate. It is one of the strongest wines in common use. According to Dr. Muspratt, of Liverpool, the alcohol in genuine port never exceeds 19 per cent. (*Med. Times and Gaz.*, Oct. 1856, p. 355.)

Madeira is the strongest of the white wines in general use. It is somewhat acid, and, when of proper age and in good condition, has a rich, nutty, aromatic

flavour. As it occurs in the market, however, it is of very variable quality, on account of the adulterations and mixtures to which it is subjected after importation. The madeira consumed in this country is generally better than that used in England; its adulteration being practised to a less extent with us, and our climate being more favourable to the improvement of the wine. At present, however, little genuine is to be found, in consequence of the destruction of the vine in Madeira; but, as the grape culture is said to have been resumed in the island, we may hope for a speedy return of the wine to the market.

Teneriffe is a white wine, of a somewhat acid taste, and, when of good quality, of a fine aromatic flavour. Its average strength is about the same as that of sherry. It is made from the same grape as madeira, to which it bears a close resemblance.

Claret, called in France *vin de Bordeaux*, from its being produced near that city, in the district of Medoc, is a red wine, and from its moderate strength is ranked as a light wine. It has a deep-purple colour, and, when good, a delicate taste, in which the vinous flavour is blended with some acidity and astringency. The most esteemed kinds are the clarets called *Château-Margaux*, *Château-Lafite*, and *Château-Latour*. Another celebrated variety is the *Château-Haut Brion* of the Pays de Grave. Claret is the French wine most extensively consumed in the United States.

Dr. H. Bence Jones has ascertained the acidity of equal bulks of the above wines, except teneriffe, expressed in grains of caustic soda. The bulk taken was that of 1000 grs. of water at 60°, and the numbers express the extremes of acid; sherry, 1·95–2·85; port, 2·10–2·55; madeira, 2·70–3·60; claret, 2·55–3·45. The same authority has determined the proportion of sugar to the ounce in sherry, port, and madeira, expressed in grains: sherry, 4–18; port, 16–34; madeira, 6–20. Claret contains no sugar. Assuming that the sugar becomes acid in the system, the order of acidity of these wines, beginning with the least acid, is claret, sherry, madeira, port. (*Chem. Gaz.*, Jan. 16, 1854, p. 35.)

Dr. Christison considers it a mistake to suppose that wines become stronger by being kept a long time in cask. His experiments appear to prove the reverse. While, however, the wine is not rendered more alcoholic by age, its flavour is improved, and apparent strength increased. It becomes less acid partly by the deposition of tartar, and probably also by the reaction between the acids and alcohol resulting in the production of ether.

Composition. Wines consist mainly of water and alcohol. They contain also volatile oil, œnanthic ether, grape sugar, sometimes glycerin in minute proportion (*Journ. de Pharm.*, Oct. 1859, p. 292), gum, extractive, colouring matter, tannic, malic, phosphoric, carbonic, and acetic acids, bitartrate of potassa (tartar),* and tartrate of lime. The volatile oil has never been isolated, but is supposed to be the cause of the delicate flavour and odour of wine, called the *bouquet*. According to Dr. F. L. Winckler, the bouquet depends upon the presence of a nitrogenous compound of a volatile organic acid with a volatile base, which has a different smell in different wines. *Œnanthic ether* (*œnanthate of oxide of ethyl*) was discovered in wine by Pelouze and Liebig. It is obtained towards the end of the distillation of wine, on the great scale, for making brandy. It forms only about one part in ten thousand of the wine. It is a colourless liquid, having a peculiar vinous odour, and a taste at first slight, but afterwards acrid. It is considered to be identical with *pelargonic ether*, under which head, in *Part* III., it is more fully described. Œnanthic ether must not be confounded with the substance which gives rise to the bouquet of wine. The other ingredients

* M. Phipson has recognised in some wines, especially a red wine of Meudon, and in some clarets from Bordeaux, the *biracemate* or *paratartrate of potassa*, which he distinguished by the shape of its crystals floating in the wine, and afterwards separated and examined by chemical tests. The crystals are in octagonal tables, partially coloured by the red matter of the wine. He considers its presence as an evidence of good quality in the wine. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 274, A. D. 1866.)—***Note to the thirteenth edition.***

of wine, just enumerated, are sometimes present and sometimes absent. Thus, sugar is present in sweet wines, tannic acid in rough wines, and carbonic acid in those that effervesce. The different kinds of wine derive their various qualities from the mode of fermentation, the nature of the grape, and the soil and climate in which it may have grown. The alcohol in pure wine is that which results from the vinous fermentation, and is intimately united with the other ingredients of the liquid; but with almost all the wines of commerce a portion of brandy is mixed, the state of union of which is probably different from that of the natural alcohol of the wine. By the British custom-house regulations, 10 per cent. of brandy may be added to wines after importation; but to good wines not more than 4 or 5 per cent. is added.

Most wines on being kept form deposits, whether in the cask or in bottles. M. L. Pasteur divides these deposits into three kinds. 1. One consists of crystals of bitartrate of potassa, of neutral tartrate of lime, or of a mixture of the two salts. This does not adhere to the sides of the vessel, but has sufficient weight to collect in a small bulk on repose. It is productive of little inconvenience physically, and has no injurious chemical effect on the wine. 2. A second deposit, often confounded with the first, but altogether distinct, is formed of the colouring substances which adhere to the sides of the bottles, especially the most dependent. It is owing to the oxidation, through the air, of the soluble colouring matters of the wine, which thus become insoluble. In consequence of its adhesion to the bottle, it allows the wine to be poured off quite clear. Its formation is generally coincident with improvement in the wine, which becomes at the same time lighter coloured, so that, after many years, the red wines, like port, will be almost as light as madeira. 3. The third kind of deposit is the most troublesome and injurious. It consists of cryptogamic vegetations, which, in the opinion of M. Pasteur, are the exclusive cause of all the alterations in wines which are considered as maladies. These never adhere to the sides of the bottle, unless confined by the colouring matter, which is very rare. They are little bodies so light that the least movement of the bottle disturbs them, and the liquid becomes turbid to a considerable extent. In a mere physical point of view, therefore, they are very inconvenient, by interfering with the decanting of the wine; while, acting as ferments, they cause great mischief not only by the change of the principles of the wine, but by adding to it new products, the direct result of their own action. As most wines are under their influence, the injury they produce in destroying the better qualities of wine is incalculable. (*Journ. de Pharm. et de Chim.*, 4e sér., ii. 40, A. D. 1865.) The remedy for this disorder in wines, suggested by M. Pasteur, is to destroy the cryptogams by the aid of heat. All that is necessary is, by means of a water-bath, to expose the wine, in bottles, to a heat of 140° to 160° F. Experience has shown that in this way the wine soon clarifies itself, keeps well afterwards, and with an improved flavour. The process of heating their wines was to some extent employed by the ancients. Appert was the first in modern times to try it; and in fact it is nothing more nor less than his own peculiar process for preserving vegetable liquids. M. de Vergnette-Lamotte also experimented with wines with the same effect; but the theory of the change was first made known by Pasteur. (*Ibid.*, iii. 118, A. D. 1866.)

The intoxicating ingredient in all wines is the alcohol which they contain; and hence their relative strength depends upon the quantity of that substance entering into their composition. The alcohol, however, naturally in wine, is so blended with its other constituents as to be in a modified state, which renders it less intoxicating and injurious than the same quantity of alcohol, separated by distillation and diluted with water. Mr. Brande published in 1811 a very interesting table, giving the percentage by measure of alcohol of the sp. gr. 0·825 in different kinds of wine. Similar tables have since been published by M. Julia-Fontenelle, Dr. Christison, and Dr. H. Bence Jones. An abstract of their results is given in a table on the next page; the results of Julia-Fonte

nelle being distinguished by F., those of Dr. Christison by C., and those of Dr. Jones by J. The rest are Mr. Brande's.*

Adulterations. Wines are very frequently adulterated, and counterfeit mixtures are often palmed upon the public as genuine wine. Free sulphuric acid in red wines cannot be detected by barytic salts; for all wines contain a small quantity of the soluble sulphates. It may be discovered, however, by dropping the suspected red wine on a piece of common glazed paper, containing starch. If the wine be pure, the spot, when dry, will be violet blue, and the paper unaltered in texture; but, if the wine contain even a thousandth part of sulphuric acid, the paper will be spotted rose-red, and prove brittle and friable when slightly rubbed between the fingers. (*Lassaigne, O. Henri,* and *Bayard.*) Formerly the wine dealers were in the habit of putting litharge into wines that had become acescent. The oxide of lead formed with the acetic acid acetate of

Prof. Diez, of Madrid, has ascertained, among other points, the percentage in volume of alcohol, and the percentage of acid, determined by potassa, in forty Rhenish wines. He found these constituents to vary, the former from 12·2 to 9·5 per cent.; the latter from 0·779 to 0·332. (*Central Blatt,* Aug. 26, 1854, p. 651.)

Estimation of the Alcoholic Strength of Wines. Mr. Horsley, of London, gives the following mode of ascertaining the percentage of alcohol in wines. Note the sp. gr. of the wine. Then take 5 fluidounces of it, boil it down in a flask to 2 fluidounces, and allow it to cool. All the alcohol is thus driven off. Add to the residuary liquid sufficient distilled water to bring it to the original measure of 5 fluidounces, and ascertain the sp. gr. of the mixture. Deduct the excess of its sp. gr. over 1·000, which is the sp. gr. of distilled water, from the sp. gr. of the wine as at first noted, and the difference will be the sp. gr. of the alcohol and water in the wine. Then by consulting the tables giving the percentage in alcohol of liquids containing alcohol and water, the percentage of alcohol in the wine will be obtained. Thus, suppose the sp gr. of the wine to be 0·997, and that of the liquid, after treatment as directed, 1·020. Then 0·020, the excess of the latter sp. gr. over that of water or 1·000, deducted from 0·997, give 0·977 as the sp. gr. of the mixed alcohol and water in the wine, which, by referring to the table on page 80, will be found to indicate a percentage by weight of 18 of absolute alcohol. (*Chem. News,* Oct. 19, 1861.)—*Note to the twelfth edition.*

lead, which, being sweet, corrected the defect of the wine, but at the same time rendered it poisonous. At the present day, this criminal practice is wholly abandoned. The adulteration is readily detected by sulphuretted hydrogen, which causes a black and flocculent precipitate. Mr. Brande, among the numerous samples of wine of suspected purity which he examined, did not find one containing any poisonous ingredient fraudulently introduced. Lead, in minute quantity, may sometimes be detected; but is derived invariably from shot in the bottle, or from some analogous source. Rhenish wines, when acid from the presence of free tartaric or acetic acid, may be restored by the addition of neutral tartrate of potassa, which gives rise to the formation of cream of tartar. (*Andrew Ure.*) Spurious mixtures, frequently containing very little of the fermented juice of the grape, and which are sold as particular wines, may not be poisonous; but they are, notwithstanding, highly pernicious in their effects upon the stomach, and always produce mischief and disappointment, when depended on as therapeutic agents. The wines most frequently imitated are port and madeira; and cider is the chief ingredient in the spurious mixtures. *English port* is sometimes made of a small portion of real port, mixed with cider, juice of elder berries, and brandy, and rendered astringent with logwood and alum. According to Stracke, genuine wines do not contain salts of potassa in quantity sufficient to yield a precipitate with bichloride of platinum. If, therefore, a suspected wine be evaporated to dryness, and the extract, after being washed with alcohol so long as this is coloured by it, and then dissolved in water, give a precipitate with the bichloride, the presence of cider may be suspected. (*Journ. de Pharm.*, Mai, 1862, p. 442.) By most dealers in wine, colouring is employed, made usually of elder berries and alum. The practice of colouring wines is very reprehensible. In France colouring is openly sold with impunity, and extensively employed; although the wine dealer who uses it is liable to fine and imprisonment. (*A. Chevallier.*) Alum may be detected in red wine by boiling it for a few minutes. If alum is present, even in $\frac{1}{3000}$ part, the wine gradually becomes turbid, and furnishes a flocculent precipitate; while a pure red wine is not rendered turbid, even by long boiling. (*J. L. Lassaigne.*)

The weaker wines often spoil by keeping. In this case they are apt to dissolve any tartar that may have been deposited, and have been found to contain propionic acid. The result is ascribed by M. Nicklès to a fermentative decomposition of the tartar. Of course, in this state the wine contains potassa, and would not respond favourably to the test of bichloride of platinum above given. (*Journ. de Pharm.*, Août, 1862, p. 90.) Lactic acid is one of the products of the changes which take place in the spontaneous deterioration of wine; and M. Balard has succeeded in discovering the peculiar lactic acid ferment in spoiled wines. The appearance of this is preceded by that of globules similar to those of yeast; and, after the completion of the lactic acid fermentation, and the commencement of the putrefactive, a throng of vibriones is observable. After the cessation of the vinous fermentation, and during the progress of that of lactic acid, all disengagement of gas ceases. (*Ibid.*, Juillet, 1862, p. 9.)

Besides the grape, a number of other fruits yield a juice susceptible of the vinous fermentation. The infusion of malt, also, is capable of undergoing this process, and becomes converted into the different kinds of porter and ale. The product in all these cases, though not commonly called a wine, is nevertheless a vinous liquor, and may be classed among the wines properly so called. The following is a list of these vinous liquors, together with the percentage of alcohol which they contain, as ascertained by Mr. Brande: currant wine, 20·55; gooseberry wine, 11·84; orange wine, 11·26; elder wine, 8·79; cider, from 5·21 to 9·87; perry, 7·26; mead, 7·32; Burton ale, 8·88; Edinburgh ale, 6·20; brown stout, 6·80; London porter, 4·20; small beer, 1·28. Dr. H. Bence Jones gives the following percentages of alcohol in the under-named liquors: cider, from 5·4 to 7·5; bitter ale, from 6·6 to 12·3; porter, from 6·5 to 7·0; brown stout, from 6·5 to 7·9. According to L. Hoffmann, Burton ale consists, in the 100 parts, of carbonic acid 0·04, absolute alcohol 6·62, extract of malt 14·97, and water 78·37;

and pale ale, of carbonic acid 0·07, absolute alcohol 5·57, extract of malt 4·62, and water 89·74. None of these liquors should be kept in leaden vessels, for fear of being rendered poisonous.

Medical Properties and Uses. Wine is consumed in most civilized countries; but in a state of health is at least useless, if not absolutely pernicious. The degree of mischief which it produces depends on the character of the wine. Thus, the light wines of France are comparatively harmless; while the habitual use of the stronger wines, such as sherry, port, madeira, &c., even though taken in moderation, is always injurious, as having a tendency to induce gout and apoplexy, and other diseases dependent on plethora and over-stimulation. All wines, however, when used habitually in excess, are productive of bad consequences. They weaken the stomach, produce disease of the liver, and give rise to gout, dropsy, apoplexy, tremors, and not unfrequently mania. Nevertheless, wine is an important medicine, productive of the best effects in certain diseases. As an article of the materia medica, it ranks as a stimulant and antispasmodic. In the convalescence from protracted fever, it is frequently the best remedy that can be employed. In certain stages of fever, and in extensive ulceration and gangrene, this remedy, either alone, or conjoined with bark and opium, is often our main dependence. According to Dr. Stokes, of Dublin, the weakness or absence of the first sound of the heart is an indication for the use of wine in typhus fever. When given in low febrile affections, if it increase the fulness and lessen the frequency of the pulse, mitigate delirium, and produce a tendency to sleep, its further use may be deemed proper; but, if it render the pulse quicker, augment the heat and thirst, produce restlessness, or increase delirium, it should be immediately laid aside as injurious. In some convulsive diseases, as for example tetanus, wine, liberally given, has often proved useful.

Wine, when used medicinally, should be good of its kind; for otherwise it will disagree with the stomach, and prove rather detrimental than useful. The individual wine selected for internal exhibition must be determined by the nature of the disease, and the particular object in view. Sherry, when in good condition, is a fine wine, and, as it contains very little acid, is to be preferred whenever the stomach is delicate, or has a tendency to dyspeptic acidity. Good madeira is the most generous of the white wines, particularly adapted to the purpose of resuscitating debilitated constitutions, and of sustaining the sinking energies of the system in old age. The acidity, however, of pure madeira causes it to disagree with some stomachs, and renders it an improper wine for gouty persons. Teneriffe is a good variety of white wine for medicinal use, being of about the medium strength, and agreeing very well with most stomachs. Port is generally used in cases of pure debility, especially when attended with a loose state of the bowels, unaccompanied with inflammation. In such cases it often acts as a powerful tonic as well as stimulant, giving increased activity to all the functions, especially digestion. Claret is much less heating, and is often useful on account of its aperient and diuretic qualities. Champagne is applicable to the sinking stage of low fevers with irritable stomach, and is often useful in the debility of the aged.

All the acidulous wines are contraindicated in the gouty and uric acid diathesis; as they are apt to convert the existing predisposition into disease.

The quantity of wine which may be given with advantage in disease is very variable. In low fevers it may be administered to the extent of a bottle or more in twenty-four hours, either pure, or in the form of *wine-whey*. This is made by adding to a pint of boiling milk, removed from the fire, from a gill to half a pint of white wine, straining without pressure to separate the curd, and sweetening the clear whey with loaf sugar. Wine-whey often forms a safe and grateful stimulus in typhoid fevers, and other febrile affections, which, after depletion, may tend to a state of deficient action, and be accompanied with a dry skin. Under these circumstances, it generally acts as a diaphoretic, and, when used of moderate strength, does not stimulate the system injuriously.

M. Aran, of Paris, has found enemata of wine highly useful in the convalescence from severe diseases. He has also derived benefit from them in chloro-

sis, dyspepsia, gastralgia attended with debility and gastric irritability, vomiting of food, and obstinate diarrhœa, especially that of phthisis. The rectum should be emptied by a laxative enema, immediately before giving the vinous, which may consist of from five to eight fluidounces of tepid wine, generally diluted with water. (See *Am. Journ. of Med. Sci.*, July, 1855, p. 208.)

Pharmaceutical Uses. White wine is employed as a menstruum to extract the virtues of several plants; and the preparations formed are called *vinous tinctures* or *medicated wines.* Tartar emetic and iron are the only mineral substances prepared in a similar manner. (See *Vinum Antimonii* and *Vinum Ferri.*) For the peculiar powers of wine as a menstruum, see *Vina Medicata.* B.

VIOLA. *U. S. Secondary.*

Violet.

The herb of Viola pedata. *U. S.*

Violette odorante, *Fr.;* Wohlriechendes Veilchen, *Germ.;* Violetta, *Ital.;* Violeta, *Span.*

Viola. *Sex. Syst.* Pentandria Monogynia. — *Nat. Ord.* Violaceæ.

Gen. Ch. Calyx five-leaved. *Corolla* five-petaled, irregular, horned at the back. *Anthers* cohering. *Capsule* superior, three-valved, one-celled.

This genus includes numerous species, of which, though perhaps all or nearly all are possessed of analogous properties, one only, the *V. pedata*, is now officinal; the *Viola odorata*, formerly recognised by the London and Edinburgh Colleges, having been rejected by the British Council. *Viola ovata*, an indigenous species, has been recommended as a remedy for the bite of the rattlesnake. (See a paper by Dr. Williams in the *Am. Journ. of Med. Sci.*, xiii. 310.) As *V. odorata* has long held the most conspicuous place in the genus, medically considered, we shall treat of it together with the officinal species.

Viola pedata. Willd. *Sp. Plant.* i. 1160; Curtis, *Bot. Mag.* 89. This is an indigenous species, without stems, glabrous, with many-parted, often pedate leaves, the segments of which are linear-lanceolate, obtuse, and nearly entire. The flowers are large and of a beautiful blue colour, often more or less variegated. The divisions of the calyx are linear and acute. The stigma is large, compressed at the sides, obliquely truncate, and perforate at the apex. The plant grows in dry sandy hills and fields, and rocky woods, from New England to Carolina, and flowers in May and June.

Viola odorata. Willd. *Sp. Plant.* i. 1163; Woodv. *Med. Bot.* p. 251, t. 89. This is a small, pretty, creeping plant, the runners of which are furnished with fibrous roots, and send up annually tufts of leaves and flowers. The leaves are heart-shaped, crenate, and supported on long petioles. The flowers are at the summit of delicate, quadrangular, channeled, radical peduncles. The leaves of the calyx are shorter than the petals, which are obovate, obtuse, unequal, and of a bluish-purple or deep violet colour, except at the claws, which are whitish. The two lateral petals are spreading and bearded towards the base, the inferior furnished with a large spur, and the two upper reflected. In the centre are the stamens with very short filaments, and anthers slightly cohering by an orange-coloured membranous expansion.

The sweet violet is a native of Europe, growing in woods, hedges, and other shady places. It is cultivated in gardens both for its beauty and for medical use, and has been introduced into this country. It is valued chiefly for its flowers, which appear in April and May.
